Thus, three approaches to the study of economic ecosystems can be distinguished. Proponents of the first approach rely on the narrower concept of "ecosystem", which historically goes back to the natural sciences, as the unity of living organisms and the environment, and therefore focus on the impact of human economic activity on the natural environment [10]. Proponents of the second approach consider the use of a single digital environment (digital platforms, applications, etc.) to be the main sign of business ecosystems. Proponents of the third approach consider the "socio-economic ecosystem" in the broad sense, as a combination of economic agents, organizations associated with a common location, as well as economic relations and participation in the creation of common socio-economic values.

S. Doroshenko and A. Shelomentsev note that while the study of economic ecosystems is carried out on the basis of a diverse methodology: institutional, evolutionary, sociocultural, etc., which has both advantages (methodological flexibility) and disadvantages (methodological eclecticism) [5]. For Russian scientists, an extended (third) approach, based on a combination of the systemic method, the methodology of spatial economics and some other methodological and theoretical tools, is more characteristic. G. Kleiner notes that ecosystem development is of particular importance for the Russian economy, the main feature of which is its lack of system, which is manifested in territorial, substantive and social fragmentation, inconsistency of decisions made at almost all levels and the absence of a generally recognized strategy at all levels of management [11].

In the structure of socio-economic ecosystems, G. Kleiner identifies the organizational structure, infrastructure, communications, and the innovative component. The organizational structure forms the "framework" of the socio-economic ecosystem and consists of business units, non-profit organizations, etc.; infrastructure component ensures the integrity of the internal space of the ecosystem; the communication component forms the links between the elements of the ecosystem; the innovative component makes it possible to create new benefits and develop the ecosystem as a whole. An important role in the sustainable development of the country's economy as a whole is played by industrial ecosystems, which are the basis for the development of territories, industries, and economic sectors.

One of the most important problems of modern economic science and practice is the problem of sustainable development [12, 13]. IMF experts highlight the economic reasons for the long-term decline in economic growth, which include a decrease in the level of investment and demand for consumer durables in both developed countries and emerging markets [14]. The main factors behind the economic slowdown are economic wars and disinflation. Trade wars, increased tensions in the field of trade and technology worsen the forecast of investment prospects and slow down the flow of investment. Disinflation complicates debt servicing and limits the use of monetary policy to counteract recessions, negative shocks, and to stimulate economic activity. A constant problem remains the decline in labor productivity in most countries of the world and recent studies prove [15] that it cannot be solved only with the help of technological factors.

The main recommendations of the IMF are to end the trade wars, as well as to pursue a soft monetary and fiscal policy in countries with low inflation and growth rates. In the medium term, fiscal policy should combine several goals: smoothing demand fluctuations, protecting vulnerable segments of the population, strengthening growth potential through government spending that supports structural reforms, and ensuring the sustainability of public finances.

The priority directions of state economic policy, many foreign scientists consider strengthening sustainability and increasing the inclusiveness of the economy, overcoming restrictions on the growth of potential output. For example, R. Hausman notes that it is inclusion that makes it possible to solve the problem of reducing labor productivity, as it facilitates access to infrastructure networks [16]. A. Guerra argues that inclusiveness provides access not only to infrastructure networks and various kinds of communications, but also to knowledge in a broad sense [17].

Consequently, economic growth in a modern economy is possible only as inclusive growth. The goal of inclusive economic growth policy is to provide access for the general population to infrastructure networks, means of communication, and knowledge. According to proponents of inclusive growth theory, this will also make it possible to solve the problems of poverty and inequality in income distribution. O. Mammadov suggested that the transition to inclusive growth will contribute to the harmonization of socio-economic relations and the development of civil society [18].

The socio-economic development of society is closely connected with the attitude of a person to knowledge, as well as with the changing role of information and knowledge in the economy and society [19]. The distinctive features of the capitalist economy are, first of all, the use of wage labor and machine production (from manufactory to factory) of products. The presence of both signs allows us to conclude that capitalist relations developed equally in the economies of both eastern and western societies. In the East, particularly in India, Russia and China, capitalist relations coexisted with the traditional way of life of society as a whole. Economic interaction was built in the framework of cooperative relations. The behavior of business entities in the East was based (and this is largely preserved today) on the principle of maximizing overall gains. In connection with these features, the development of capitalism proceeded at a slower pace. The formation of capitalist relations in

Western Europe was accompanied by revolutionary changes in the entire system of social relations [20]. During the revolutions, the balance of power between social groups changed and, as a result, the legal infrastructure of society and the motivation of behavior of business entities changed. After the Western capitalist revolutions, the main motive for economic behavior was the maximization of personal gain, and economic interactions were built in the framework of competition relations. The above features contributed to the rapid development of capitalist relations.

There is another reason for such significant differences in the pace of development of capitalism in the East and West, and it seems to us very important. We are talking about differences in the perception and application of knowledge. As P. Drucker rightly noted, "in the West and in the East, knowledge has always been correlated with the sphere of being, existence. And suddenly… knowledge [in the West] began to be seen as a sphere of action. It has become a type of resource, one of consumer services" [21]. It is known that the vast majority of discoveries and inventions were primarily made in the East, and then, often in very confusing ways, fell into the West. Undoubtedly, the fact that the practical application of many of them significantly varied in different parts of the world requires special reflection. For example, gunpowder in its historical homeland, in China, and then in Russia, was used for fireworks, but only in Western Europe they began to use it in weapons business.

In the East, knowledge has always been a tool for a person to know the essence of the world around him and himself as part of the universe. In the West, knowledge has become, above all, an instrument for transforming the world by an individual, as well as an instrument of self-realization of a person in the process of asserting oneself over the secrets of this world. So, Western man used knowledge for action, therefore it is not surprising that after the adoption of individualistic standards of economic behavior, knowledge turned into a special product, transactions with which allowed to maximize personal profit. The perception of knowledge as a product made it possible to create a legal framework in Western economies for transactions with knowledge products, and then for organizing the process of knowledge production itself.

Since the second half of the twentieth century, knowledge has been used, not only for organizing and transforming inanimate nature, but also for influencing wildlife and man in order to realize the main goal of capitalist relations, namely: profit. First, knowledge in the modern economy is a tool for organizing and transforming complexly organized technical and information systems. Secondly, knowledge is a tool for organizing and transforming living systems and individual organisms at the material (biological) level. Thirdly, knowledge is used as a tool to influence living intangible systems, namely social relations.

The evolution in the use of knowledge in the West is explained, firstly, by the fact that non-economic and economic coercion to work is supplanted by non-economic information coercion. The economic and social behavior of a person is modeled using targeted information flows. The priority of technology is superseded by the priority of needs, which are often asked from the outside, that is, are exogenous for the consumer, and endogenous for the manufacturer. Thus, the neoclassical dichotomy "maximizing utility—maximizing profit" is overcome by using information to create

needs. The consumer subjectively gives utility to those goods and services whose production allows the manufacturer to maximize profits.

The use of knowledge as an instrument of influence on the social sphere, human psychology, its economic and social behavior [22], has allowed the creation of technologies that model human behavior based on the manipulation of its natural instincts, such as sexual instinct, hunger, aggression and the desire for idleness, as well as the instinct of mass behavior. These technologies allow, in particular, to create sustainable preferences regarding this or that product, this or that model of social behavior.

At the same time, in the East, the essential perception of knowledge is dominant. There is a conflict between the Western and Eastern perceptions of knowledge, which transforms into the plane of economic and social relations. The capitalist economy of the West seeks to draw new natural resources into economic circulation, in particular, energy carriers whose deposits are concentrated in the East. As shown above, this is determined by the practical application of knowledge in accordance with the Western approach. Claims of this kind inevitably meet with a negative attitude in the East.

Thus, economic development has always increased the involvement of people in the process of obtaining and creating knowledge, and opening up access to information. In modern conditions of digitalization, knowledge has become an important factor in the development of socio-economic systems. Consequently, inclusive growth of the economy and the socio-economic ecosystems, its components, is impossible without expanding access to knowledge, information, technologies of wide layers of the population of all countries of the world.

4 Conclusions

The study of the phenomenon of socio-economic ecosystems in the modern economy allows us to draw the following conclusions:

- it has been established that in the modern economic there are differences in understanding the essence and content of economic ecosystems in Russian and foreign science; the attention of foreign scientists is focused on the study of business ecosystems and digital business ecosystems, and Russian—on the study of socio-economic ecosystems;
- it was revealed that the main factors in the development of socio-economic and business ecosystems are environmental problems and the development of digital technologies;
- it was found that the solution to the problem of slowing growth is the transition to a model of state economic policy aimed at sustainability and increasing the inclusiveness of the economy;
- it has been proved that inclusiveness as a principle for the development of the modern world should also imply access of broad sections of the population to effective institutions, information and market infrastructure in general, which

will solve the problem of a conflict of economic interests and harmonization of socio-economic relations;
- it was proved that inclusive growth of the economy and socio-economic ecosystems, its components, inevitably involves expanding access to knowledge, information, technologies of wide layers of the population of all countries of the world;
- it was found that digitalization contributes to the development of socio-economic ecosystems on an inclusive basis, which increases the sustainability and effectiveness of the entire economy.

Socio-psychological Characteristics of the Innovative Potential of Students as Indicators of Professional Elitism in a Digital Society

Anna P. Avdeeva, Svetlana A. Grishaeva, and Zhibek S. Khussainova

Abstract The digital society and, in particular, the digital economy require the employee to have certain competencies that aren't limited to computer literacy, information competencies, etc. The so-called soft skills become very popular, among which an important place is occupied by effective thinking skills, self-management skills, communication and managerial skills [2]. Soft skills are considered as a style of behavior that combines the parameters of social flexibility and individual activity. In turn, the ability to build business communications in the business environment, teamwork skills, leadership, and behavioral flexibility are decisive for innovative personality behavior, which is an integral indicator [6] of professional elitism of the personality and determines the person's ability to be adaptive to changes, generate changes, new forms of behavior and activities, change yourself, successfully carry out activities aimed at developing, implementing and disseminating new ideas, products, and technologies [3–5]. The article presents the results of a study of the socio-psychological characteristics of students' innovative potential, including value orientations, professional motivation, socio-psychological qualities, as a condition for further professional implementation [1]. It's proved that students with different levels of development of innovative potential prefer to work in companies with different types of organizational values (adochocratic, market, clan, hierarchical types of organizational culture); students with a high level of innovative potential to a much greater degree show leadership qualities, are focused on the role of entrepreneur and senior manager.

JEL Code I250

1 Introduction

A modern digital society is a society that is constantly transforming and, therefore, requires the skills of readiness to accept and manage these transformations, i.e. readiness for innovation, which is determined by the level (degree of development) of innovative potential. Value orientations, worldview features of students associated with development and transformation form the highest level of socio-psychological characteristics of innovative potential.

Value orientations are the basic forms of the functioning of values at the level of the individual and they are also determined through the concepts of goal, attitude, and personality attitudes. The value orientations reflect the semantic meaning of the value categories of creativity, innovation, development, transformation for students as a large social group.

2 Background and Methodology

Groups with different levels of development were identified to study the socio-psychological characteristics of the innovative potential of students.

Diagnostic tools included the questionnaire «Self-assessment scale of innovative personality traits». The questions of the questionnaire were grouped on two main scales: (1) activity (intellectual, social, behavioral) and (2) flexibility (emotional, intellectual and behavioral). Students had to determine their similarity to that person, and give an answer for each of the judgments using a 3-point scale—from 0 (not suitable) to 2 (completely suitable).

To establish groups of respondents which difference depending on the level of development of innovative potential, the procedure of descriptive statistics was applied - the calculation of the average value. Based on indicators of average values of the severity of innovative potential, two groups of students with a high (VIP) and an average (SIW) level of development were identified. The group with a high level of development of innovative potential included students with values above the average, and the other group included respondents with indicators of the severity of innovative potential below the average.

Student distribution results are presented in Table 1.

Table 1 Assessment of the level of development of innovative potential of students

Integral characteristics of the innovative potential of the individual	Mean ($n = 54$)	SIP average value ($n = 35$)	Average value of VIP ($n = 19$)
1. Activity			
1.1. Creative activity	1.3	1.0	1.5
1.2. Independence	1.1	0.9	1.2
1.3. Riskiness (risk appetite)	1.3	1.0	1.6
1.4. Social activity	1.5	1.2	1.7
ACTIVITY INDICATOR:	1.3	1.0	1.5
2. FLEXIBILITY			
2.1. Uncertainty tolerance	0.7	0.3	0.9
2.2. Learnability	1.4	1.2	1.6
2.3. Open to new	1.1	1.4	1.9
2.4. Creativity	1.4	1.1	1.8
Flexibility indicator:	1.1	0.7	1.6
9. Total score – The final indicator is the level of development of the individual's innovative potential	1.2	0.8	1.6

3 Results

To identify the differences between the two groups of students with a high and medium level of development of innovative potential, the nonparametric Mann-Whitney coefficient was calculated. For all indicators of innovative potential, statistically significant differences were revealed ($p \leq 0.05$), with the exception of the indicator «independence». Figure 1 shows a comparative analysis of the profile of innovative potential of students with high and medium levels of development of innovative potential.

Thus, based on a comparative analysis, we came to the conclusion that students with high innovative potential are dominated by personality traits:

- creative activity
- uncertainty tolerance
- learning ability
- riskiness
- openness to the new
- creativity
- social openness.

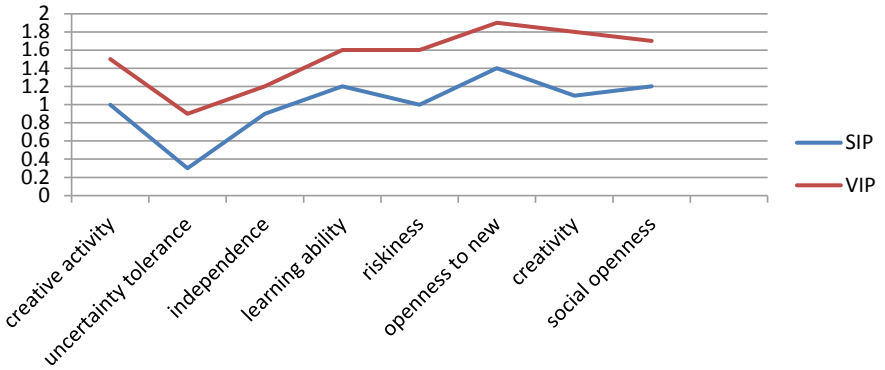

Fig. 1 Student innovation potential profiles

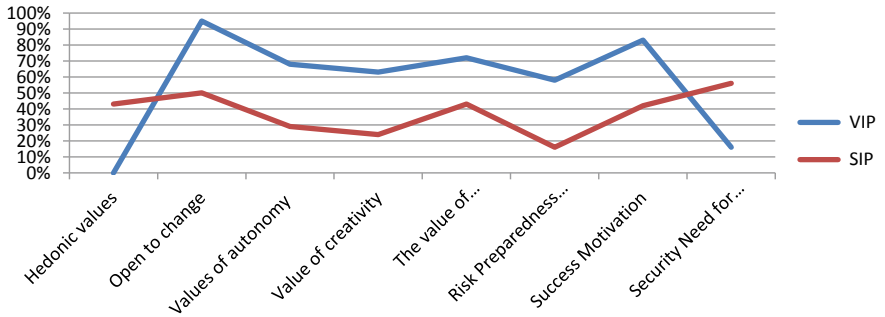

Fig. 2 Student values profile

Next, a comparative analysis of the value-semantic characteristics of the innovative potential of students with high and medium levels was carried out (Fig. 2).

The structure of values of students with an average level of development of innovative potential is dominated by hedonic values associated with the orientation of these students on a pleasant pastime and rest. The maximum value of hedonic values is characteristic for 43% of respondents in this group. In a group of students with a high level of development of innovative potential, we observe the opposite picture. So, 78% of students rated the hedonic value as completely insignificant for themselves (set the minimum value), and for 22% it has an average value.

It was found that the dominant values are openness to change as new experience, knowledge, ideas in a group of students with a high level of development of innovative potential. This value forms a positive attitude towards innovation and innovation in a professional environment. The significance of this type of value is of maximum importance for 95% of students included in this group. In the second group of students, characterized by an average level of development of innovative potential, openness to change has a maximum degree of significance for 50%. For other

students of this group, openness to the new, focus on changes is not the dominant value in their personality structure.

The values of independence (68%) and the value of creativity (63%) are also of the highest degree of significance for students with a high level of innovative potential. It's important for these students to show independence of thoughts and actions, they seek to show initiative, independence in life, work or interpersonal relationships. For students of this group, which focus on personal development, professional implementation is important life goals.

In a group with an average level of innovative potential, for 29%, the value of independence is of maximum importance, 24% of the respondents in this group consider the value of creativity as important as possible for themselves.

The value of professional development is maximally significant for 72% of students with a high level of innovative potential. They are focused on high standards in the professional field of activity, seek to achieve professional competence. 42% of students consider the achievement of professional excellence in work as an important goal in their life in a group with an average level of development of innovative potential.

Very indicative is the data reflecting differences in risk appetite for the sake of achievements among students with high and medium levels of innovative potential. More than half of students with a high level of development of innovative potential (58%) are prepared for risk for the sake of achievements. The level of their readiness for risk corresponds to the maximum values, the remaining students of this group revealed average values of indicators.

Value-based risk appetite determines an individual's focus on risky actions as opposed to cautious actions and behavior. The psychological preparedness for risk for children with high innovative potential is associated with their social attitudes—courage, determination, competition, and also the motivation for achieving success. Our research results showed that 83% of students with a pronounced innovative potential are dominated by the motivation to achieve success.

In addition, as we indicated earlier, these students are characterized by a manifestation of tolerance to uncertainty, which is consistent with the data of T. V. Kornilova et al. They emphasize that «personal risk appetite promotes cognitive risk as an effective acceptance of the conditions of uncertainty in the actual genesis of intellectual strategy» [7], p. 64).

Risk readiness is a manifestation of social readiness (according to L. Schmidt) as a tendency to act in an unusual way, to show independence and independence, not to wait for approval from other people [8]. The results of our study which showed that the need for security and stability isn't significant for 84% of students with a high level of innovative potential are also consistent with these data.

In a group of students with an average level of innovative potential, expressed (maximum value) risk appetite is typical for 12%, the rest of the children aren't expressed. At the same time, the need for security and stability in life is maximally significant for 56% of students; for 44% of children in this group, the significance level corresponds to average values. Data analysis showed that the predominance of

Table 2 Assessment results of dominant career orientations

Students career values	VIP (%)	SIP (%)
Professional competency	72	34
Management	47	26
Autonomy	67	32
Challenge	28	11
Lifestyle integration	63	46

motivation to achieve success is not typical for students in this group. This type of motivation was detected less than half of students (42%).

Summarizing the data obtained evaluating the value-semantic characteristics of the innovative potential of students; we can conclude that the level of development of innovative potential is due to the system of values and motivation.

Students with a high level of development of innovative potential are dominated by innovative values: openness to change, independence, creativity, professional development, characterized by a coordinated, consistent system of value orientations and motivation for success, readiness for transformation, which sets clear guidelines for life.

Analysis of the results of the study of students' career orientations showed their differentiation in groups with an average and high level of innovative potential. Significant differences were identified by the career orientations «professional competence», «autonomy» and «challenge». The results of the study of career orientations of students are presented in Table 2.

Diagnostic results of career values showed that students with a high level of development of innovative potential are dominated by the career anchor «professional competence» (72%). This result allows us to say that for students with a high level of development of innovative potential, the orientation to the manifestation of their talents and abilities in professional activity, the desire to realize them in innovative activity is most characteristic. In a group of students with an average level of development of innovative potential, this career orientation has a much lower frequency of occurrence—34%.

Career orientation «autonomy» characterizes the individual's desire for self-support, independence, freedom from prescriptions and restrictions. In a group of students with high innovative potential, this career orientation is predominant for 67% of respondents and it acts as a significant career reference for 32% of students in a group with an average level of innovative potential.

The main values of a person's career orientation «challenge» are related to overcoming obstacles, winning, achieving success, and competition. A person with such a career anchor is focused on challenging in various social situations; the process of overcoming difficulties, struggle and achieving success is significant for her. 28% of respondents from the group with high innovative potential have high values for this career orientation. Only 11% has an average value in a group with an average level of innovative potential,

Table 3 Orientation assessment results

IPL	Preferred organizational values			
	Adochocratic	Market	Clan	Hierarchical
	Initiative and freedom of action	Leadership and rivalry	Loyalty and cohesion	Stability and responsibility
VIP (%)	41	37	25	10
SIP (%)	22	14	29	37

In the group with an average level of development of innovative potential, 46% of children are dominated by career anchors as an integration of lifestyles, which reflects their high level of energy potential. They seek for success in life in different spheres of their life: in work, career, communication, family relationships.

The obtained results allow us to state that in a group of students with a pronounced innovative potential, the totality of dominant career orientations: professional skills, autonomy and challenge, characterizes innovative activity and flexibility in career choices. This set of career orientations characterizes the aspirations of these students for victory, independence, freedom from restrictions, independence, determination, they are focused on overcoming obstacles and aren't afraid of difficulties, difficult tasks, responsibility. They are energetic, active and focused on achievements in various spheres of their lives.

Further, we conducted a comparative analysis of the organizational orientations of students of two groups: with a high and medium level of development of innovative potential. Results reflecting students' preferences regarding organizational values (their organizational orientations) are shown in Table 3.

Based on the data processing, significant differences were revealed in groups with different levels of development of innovative potential. So, 41% of students with a high level of development of innovative potential are oriented to work in organizations with an adochocratic type of organizational culture (the core values are initiative and freedom of action. Innovation, enterprise, risk appetite and experimentation are required). 37% of students from this group would like to work in companies of the market type (core values—competitiveness, leadership, rivalry. Purposefulness, competitiveness, stress resistance are required).

It was found that the dominant organizational orientations in them are clan and hierarchical in a group of students with an average level of development of innovative potential. Thus, 29% of the respondents in this group are oriented toward work in organizations with a clan type of organizational culture (in their organizational structure they are similar to large families with a positive, friendly socio-psychological climate and a cohesive team of employees. The organizational values of such companies are associated with dedication and cohesion. Employees are encouraged by the ability to work in a team and also non-conflict. They are attracted to participate in business decisions).

36% of students with an average level of expression of innovative potential would like to work in companies with a hierarchical type of organizational culture.

These students are oriented to work in companies with strictly formalized organizational procedures, where the main corporate values are stability and responsibility. From employees, first of all, discipline and organization are required. The guys justify their choice by the fact that they are attracted by stability, job security, the availability of social benefits that organizations of the bureaucratic type can provide.

A comparative analysis of the organizational orientations of students with different levels of innovative potential showed the following differences. Students with a high level of development of innovative potential are characterized by the fact that they are oriented to work in companies where development values prevail.

Type of development values according to Prigogine [9], p. 37)—are the values of innovation, proactivity, competitiveness, leadership, determination, creativity, and professionalism. Students with a medium level of development of innovative potential would like to work in organizations with the type of values of order, well-being and relationships.

Values of order include punctuality, discipline, stability, security, responsibility. The values of well-being are associated with profitability, welfare, security, loyalty, conflict-free. Relationship values are presented as teamwork, trust, mutual commitment, respectfulness, goodwill, openness, honesty [9], p. 37).

Thus, we can conclude that students with different levels of development of innovative potential prefer to work in companies with different types of organizational values.

Socio-psychological qualities reflect the operational resources of a person, who has his significant goals for realizing. The results of the study of students communicative qualities with different levels of severity of innovative potential are presented in the diagram in Fig. 3.

Data analysis showed that in a group with high innovative potential, leadership skills are inherent in 47% of students. They have developed skills for effective communication, they are also able to establish and maintain business and informal contacts. These persons able to organize others, exert influence in the group, organize and lead teamwork. They are tolerant of uncertainty, adapt well in the new environment. Only 26% of students have developed leadership qualities in the second group with a moderate innovation potential. Most students in this group communicate and behavior is difficult because of the insufficient level of development of tolerance to uncertainty. New social situations may cause them to resist change.

We also studied the role orientations of students with different levels of innovative potential (Fig. 4). An analysis of the results of the study showed that 84% of students with a pronounced innovative potential see themselves in the social role of

Fig. 3 Leadership profile

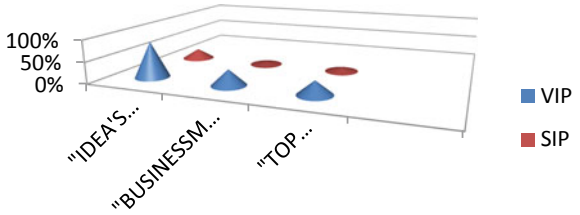

Fig. 4 Social roles

the «generator of ideas», while in a group with an average level of expression of innovative potential, 24% of students identify with this social role.

The social role of the entrepreneur is oriented to 37% of students, who are members of a group with a high level of development of innovative potential. Only 6% of students identify with this social role from a group with an average level of development of innovative potential.

32% of students with high rates of innovative potential and 9% of students from the group with an average degree of expression of innovative potential see themselves as the top managers.

Specialist, who works as a team of an innovative project, should act as an innovative leader, able to fulfill a certain functional role or roles in the process of innovative activity. The role of the innovative type is a necessary condition for the innovation process in the Merrill's theory [10]. According to P. Merrill, the group of innovators should have a distribution of roles, while a lone innovator shouldn't only harmoniously combine these roles, but also replace each other in the course of the innovation process.

He identifies four social roles associated with the main stages of the innovation process. The innovative role of «creator» is manifested in the creation of opportunities. The second innovative role of the «ranger» is connected with the search for solutions—the implementation of the path from opportunity, idea to solution. The third innovative role of the «finalist» is aimed at putting the solutions into practice. And finally, the last innovative role of the « doer » is to implement, implement solutions. These roles are crucial to the innovation process and coincide with the stages of this process.

4 Conclusion

Summarizing the results of the study of socio-psychological qualities of students with different levels of innovative potential, we can write the following conclusions. Firstly, leadership as a fundamental communicative characteristic that reflects the activity and flexibility of a person in interpersonal communication is most pronounced among students with high innovative potential. Secondly, in this group of students, role orientations associated with innovative professional activities are

more pronounced than among students with an average level of development of innovative potential. Thirdly, socio-psychological qualities act as their real opportunities to achieve the goals of innovative personal and professional development for students with a pronounced innovative potential.

Digital Business Development in the Urban Environment of the Future: Economic and Social Effects

Valentin N. Grishin, Stella S. Feshina, and Oksana V. Konovalova

Abstract Due to the rapid growth of the urban population all over the world and the emergence of methods for analyzing big data, there is growing interest in works devoted to the study of current trends in changing urban structure. Studies have shown that the «smart city» system primarily focuses on the integration of three components: economic, social and environmental. Smart cities add digital intelligence to existing urban systems, allowing you to solve more problems at lower cost. When cities function more efficiently, they become more productive places to do business. In addition, digital technology helps increase social cohesion. The social component includes, first of all, democracy with the participation of citizens. In many cases, smart cities focus on finding answers to various urban problems by introducing information and communication technologies (ICT), which are designed to collect citizen feedback or provide resources for information that can improve the quality of urban life. However, there are still few scientific and practical works in which an attempt is made to assess the possibilities of solving urban problems based on digital technologies: from citizens living to doing business in a single unified environment. The purpose of this study is to attempt to develop such a unified approach. The novelty of the study is the refinement of the concept of «smart city», the analysis of the use of its dynamic capabilities with a focus on the stages «assessing the importance of an event» and «using opportunities», where ICT technologies are used as a tool for collecting information from citizens. The proposed approach will allow municipal authorities to quickly respond to unstable situations in all areas of urban life, to justify the allocation of resources and plan their needs for the future.

1 Introduction

Currently, cities generate about 80% of global GDP [1], and this number is continuing to grow. High business and economic activity makes cities attractive for business and an increasing number of able-bodied people. The United Nations reported that by 2008, 3.3 billion people lived in cities, which exceeds 50% of the world's total population. It is predicted that by 2030 this figure will increase to 5 billion people.

Today there are 1,128 cities in Russia, taking into account the settlements of Crimea and closed administrative-territorial entities. At the beginning of 2014 about 100.5 million people or 69% of the population of Russia lived in them. Over the past 25 years, 60 settlements have acquired the status of a city. In addition, the city of Magas was built from scratch, becoming the new capital of Ingushetia [2]. Million-plus cities provide a third of Russia's GDP [3]. However, it's worthwhile to be prepared that a steady increase in the urban population will lead not only to an increase in GDP and intensive economic growth, but also to a concentration of problems—from a shortage of all types of resources to environmental degradation.

One of the revolutionary directions of inhibition of these trends in developed countries is an attempt to global transition to smart cities. In this movement, the word «smart» is usually understood as meaning the ability to be flexible in solving emerging problems in the context of an increase in the rate of change in the internal and external environment. Smart cities primarily provide intelligent services [4].

«Smart city» is a fairly new term, but in the last decade it has become increasingly popular. There are already separate cities around the world characterized as «smart», while others are only taking their first steps in this direction. The concept of «smart city» is multidimensional and, therefore, its study is an interdisciplinary topic—from the areas of computer science, engineering, urban planning to political science, economics and social research.

2 Background and Methodology

The authors used universal scientific methods, including methods of idealization, communication and abstraction, formalization. As experimental methods, the authors used methods of observation and comparison. Much attention was paid to the study of data based on the analysis of news texts.

A clear and unified definition of a smart city hasn't yet been formulated in the research environment and in practice. Different sources use different terminology to describe a smart city—an intelligent city, a digital city, a sustainable city, a tech city, or a city of well-being. One of the reasons for the lack of clarity is the fact that the emergence of a smart city isn't a top-down development process, but a bottom-up phenomenon. The rapid development of technologies in IT industries has determined the development of the functional infrastructure of the smart city towards integration of the provided social services, their management and involvement of representatives of business structures and citizens in these processes in order to increase the efficiency of the urban economy and economy [5]. Each of these changes is important, and smart cities are at the intersection of them all.

Although the functional infrastructure of a smart city is crucial, it can't be fully exploited without the participation and cooperation of citizens, without raising the level of education and developing new competencies, especially among young people [6]. In this context, the word «smart» implies not only intelligence capable of solving problems and adapting to changes, but also ensuring the convenience of its using.

In addition, there is no proper and reliable methodology that allows a structural analysis of problems and solutions identified and perceived by citizens.

Therefore, the purpose of this study is to develop an approach to building a dynamic model to determine the problems and solutions of the city from the point of view of citizens and to determine the place of this model as part of a wider system of a smart city.

In this regard, the authors are supposed to consider two issues.

1. How can smart cities more fully engage citizens and business representatives in identifying opportunities for positive change in today's dynamic and complex environment?
2. How can smart cities use data analytics to identify solutions to problems and positive changes?

3 Discussion and Results

Since the 2000s, the computing power of devices has continued to grow, sensors have become cheaper and more affordable, and microcomputers have become inexpensive and easy to use. These hardware improvements in all spheres of human activity have led to the possibility of obtaining, accumulating and accessing large amounts of information, integrating existing computer systems, creating information repositories, and reducing redundant work on manual system integration [7].

ICT developers foster the widespread adoption of the Internet of Things (IoT) and provide services and products that integrate sensors, cameras and information systems [8]. In this context, integrated systems, which include, for example, sensors that measure the quality of water or air and transmit the results to the appropriate city services, help them respond more effectively in terms of saving time and resources in solving problems.

This integration is especially important in addressing the issues of ensuring the safety of life and human activities and also managing operations in the event of an emergency [9].

Another example of the Smart City project is the building automation system with adaptive dynamics, in which buildings are equipped and programmed to respond to environmental changes. This solution was developed by Siemens Building Technologies Department (IC BT) [10] and is intended for all participants in the building design process, and especially building automation systems.

This work is based on the European standard EN15232:2012 «Energy performance of buildings; impact of Building Automation, Controls and Building Management» and eu.bac (European Association of Building Automation Systems). Utilizing the cost-effective functions of building automation systems reduces operating costs, saves energy and reduces CO_2 emissions. Data from the system can be accumulated and analyzed over time to find patterns for the most economical use of energy. These types of technologies are becoming an important part of the smart city system.

It's worth noting that the definition of a «smart city» by city authorities differs from the definitions in the scientific literature [11]. The main focus of government officials in the concept of the «smart city» and the projects of the «smart city» was given to administrative transformations carried out with the help of ICTs focused on citizens. In this form, they are presented as a function of the second level among the projects of the «smart city» aimed at creating a culture of civic initiative of the «smart city».

An open government, also known as Government 2.0, which is a developed version of e-government in the 2000s and subsequent years, includes a transformation that requires a constructive dialogue between government, business and citizens. Citizens-oriented e-government requires governments to actively seek what citizens want [12]. Citizen participation, not only in the form of voting, but also in conducting state polls, is currently considered one of the pillars of e-government [13].

Bringing together stakeholders who may have different needs and balancing their interests until they identify appropriate initiatives, which create value for their city, can be a problem. When data is collected from sensors, information systems process and analyze them to understand situations, create knowledge, discover patterns, and identify opportunities for positive change. The resulting initiatives can improve the effectiveness of the action and the quality of services provided by the city. Relevant intelligent technologies can be seen in the areas of transport, traffic monitoring, energy, water, waste management and many other areas of urban management.

However, combining the information, which is received from individual business entities and citizens, and identifying the patterns, which are used to achieve consensus and identify specific solutions to urban problems requires a different approach [14]. As the city goes into digital management, the involvement of business and citizens moves from the role of the public as a participant to the joint design and implementation of government functions using user-generated content or engaging citizens in the joint creation of public services (public capital).

Data from user-generated content using analytics can then be used to create predictive models that anticipate services, allowing local governments to move from a

reactive to a proactive response to citizen needs. The resulting opinion can be heard not at the level of an individual with the advent of text analytics, but at the collective level of a community of citizens and business representatives. Once a trusting relationship has been established between government, business, and citizens, regular data sharing can provide an opportunity to pre-evaluate proposed innovations.

It's clearly that smart cities start with smart communities [15]. As we move from community level to city level, the administrative environment begins to be crucial to supporting the development of smart cities. At an early stage of development, the administration should help local initiatives develop and gain the necessary momentum, which will allow unite separate groups of civil communities with other interested partners (business, non-profit organizations, etc.) on dynamic principles later.

Since the late 1990s, dynamic opportunities were initially considered in the context of implementing an organizational strategy, and then expanded to information systems and e-government. Dynamic capabilities include the organization's ability to sense the environment and transform itself. A city can also identify problems like any other organization, collect and accumulate information, and then analyze it.

The authors distinguish three main dynamic features of a smart city:

(1) sustainability or the ability to avoid over-exploitation of resources;
(2) stability or the ability to return to balance after a crisis;
(3) flexibility or the ability to develop and adapt.

The analyst acts as a tool for a dynamic model while he is building integrated information systems in a smart city. Ensuring and encouraging the inclusion of every citizen in the process of identifying problems and seeing positive opportunities is considered as an element of the indicative (sensitive) component, and the accumulation of a set of civic opinions (votes) as the basis of the analytical component of the smart city model.

Obviously, the goal of transforming the city into «smart» can't be achieved without the contradictions and resistance of stakeholders [16]. There are certain differences between the private and public sectors—government changes are usually embedded in legal, regulatory and administrative frameworks, and private interests require consideration of social aspects. Thus, there is a need to harmonize the demands and constraints of the existing social, legal, regulatory and administrative environments as a new component of the model of the dynamic capabilities of a smart city. The model proposed by the authors is shown in Fig. 1.

The classical approach to the stages of regulating the interests of city development includes: identification of importance, using, transformation. It is transformed in the model of dynamic opportunities in the context of a smart city: identification of importance (identification of positive opportunities and/or problems), using, coordination (reconciliation/balancing/smoothing) and transformation. These steps are shown in Fig. 1 as part of an iterative (or parallel) process with continuous conversion cycles.

Based on the considered approaches to building a model of the dynamic capabilities of a smart city, the authors give the following definition.

Smart city is:

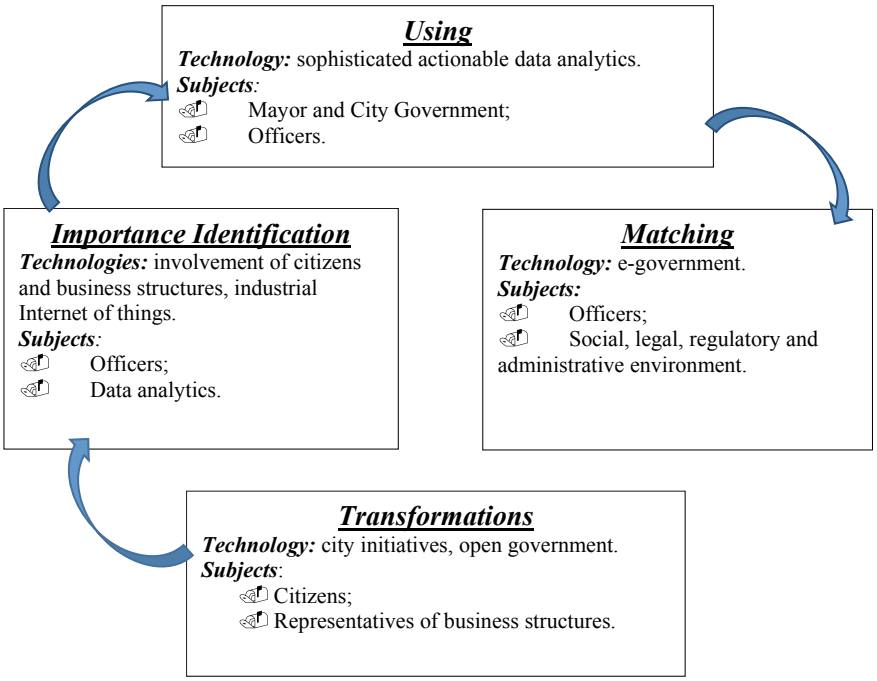

Fig. 1 The dynamic capabilities of a smart city and related entities, processes and technologies (created by the authors)

- The organization as a whole, with dynamic capabilities, because it includes assets, resources, infrastructure that connects them; processes that acquire, support and use these resources; goals that provide these processes with direction; management that sets goals and manages processes and resources, the environment in which it operates.
- The city organization, due to its assets include private and public spaces, its resources include renewable and non-renewable, such as: energy sources, food and building materials, as well as resources that satisfy the biological needs of the population. Its infrastructure includes services and services, such as: roads, waterways, water supply, sewage, transport and communication networks, educational, service and public security services. Its objectives include maintaining certain standards of vitality, sustainability and welfare of citizens. Its management includes processes of interaction and decision-making between participants interested in creating and maintaining certain institutions, such as: a legal system, an education system and a network of trading floors. And his environment includes the natural, political and socio-economic elements that surround him.

A smart city has dynamic capabilities because it uses its resources to perceive opportunities and threats in the internal and external environment, use the opportunities to achieve its goals, coordinate goals with the existing environmental, social,

economic, legal, regulatory and administrative environment and transform itself to get closer to these goals.

The presence and awareness of the possibilities of dynamic changes makes the smart city an organization of knowledge, because it uses its resources and processes to create new values, distributing them through the integrated infrastructure systems of the smart city and also introducing them into products, services and management processes in the form of hidden or explicit knowledge.

4 Conclusion

As part of the study, potential approaches to building a dynamic model of a smart city were considered. Undoubtedly, every city that sets itself the task of becoming «smart» must understand first of all: decision of what tasks is the priority of this project. In each case, whether it is the development of knowledge capital or industrial or service technologies, the design of a smart city will have its own specifics.

The main result of this work, including elements of scientific novelty, is the realization that it becomes possible to redefine a smart city on the basis of these approaches as an urban organization with dynamic capabilities, which operates as part of cycles of awareness of the importance of problems or opportunities, using of collected information and balancing and transforming functions. It's suggested that approaches to model building can be an interesting theoretical view and a useful roadmap for practitioners and politicians who are looking for ways to increase the economic and social efficiency of a smart city in creating positive changes.

Neural Networks in the Digital Economy

Elena A. Gubareva and Ekaterina Shemyakova

Abstract An analysis of the mathematical models and methods, which are used to build the algorithms of the digital sector of the economy, made it possible to draw the following conclusion: the modern development of mathematics and information technology provides a wide range of possibilities for setting and solving various problems in the field of economics. One of them is the analysis of time series in order to predict the behavior of a dynamic system. The ability to use artificial neural networks for this is justified by the theorems of mathematics by Takens, Gorban, and Kolmogorov, which made it possible to reduce the problem of forecasting time series to the problem of approximating a continuous function of several variables. Based on the analysis of neural networks and modern methods of their training, a phased construction of the ANN, which determines the main characteristics of the ANN, is proposed, the correct choice of which will allow to qualitatively solve the task of forecasting the time series. The main stage of the scheme under consideration is the selection and training of a neural network, which requires an assessment of all possible architectures and methods for training neural networks, since there are still no general criteria to confidently choose the optimal «methodology» for training a neural network, despite their active using. The choice of the most important properties of a neural network: its architecture, block size, learning speed, remains largely empirical. A high-quality solution to any economic problem requires a comprehensive analysis of existing training algorithms for neural networks in order to choose the best one. This inhibits using of ANNs to solve the practical problems of the economy. It's proposed to use artificial neural networks (ANNs) only to solve such problems of economics and management, where the formalization of the decision stages is either quite complicated or impossible at all.

1 Introduction

A review of the current understanding of the digital economy can be found in the article by Kozyreva [1]. It gives a historical retrospective of the emergence and development of the concepts of digital economy and digitalization from the first appearance of the term «Digital Economy» (digital economy) to the current state of work in this direction. The works of many authors [2–4] discuss the problems and prospects of the development of the digital economy in Russia.

With the development and implementation of the digital economy, there shouldn't be a process of replacing the goals and objectives of the digital economy with the simple tasks of replacing paper workflow with its electronic counterpart.

Digitalization must penetrate the real economy. The key to success is the fact that behind the word «digitalization» is a powerful mathematical apparatus, the presence of which provided the beginning, development and implementation of it in the economy and our everyday life.

It must be remembered that behind any digital ability to solve a particular problem is a mathematics or mathematical model. The software, which is used in the form of MATLAB, Excel, doesn't replace mathematics, but it allows real-time solution of labor-intensive tasks using various mathematical methods and models.

For example, one of the main tasks in the sphere of digitalization of the educational process is the task of scheduling. One of the leaders in the Russian market of digital scheduling programs is the program «1C: Automated scheduling» [5]. A mathematical model of integer linear programming is the heart of any scheduling algorithm.

The need to take into account a large number of parameters: the number of student groups, the number of subjects, the number of teachers in each subject, the types of classrooms (lecture, seminar and computer), their number and location, the number of pairs makes this task quite time-consuming. The combination of these parameters gives many possible events, on which various conditions necessary to maintain the educational process are superimposed. This makes the scheduling task very difficult. In reality, the schedule is compiled in most cases manually, or the electronic version of the schedule requires substantial revision.

An analysis of the mathematical models and methods, which is used to construct the algorithms of the digital sector of the economy, made it possible to draw the following conclusion: the modern development of mathematics and information technology provides a wide range of possibilities for the formulation and solution of various problems in the field of economics.

We consider, for example, the well-known discrete optimization problem, namely, the knapsack problem (Sigal and Ivanova 2002). Since the problem is discrete, method of simple enumeration of all feasible solutions from G, which power is 2^n, where $n-$ zero vector order, can be one of the ways to solve the problem. Moreover, for each feasible solution, the calculation of the objective function of the form is performed $\sum_{i=1}^{n} x_i v_i$. If, $n = 20$, then search volume is $2^{20} \approx 10^6$, and if $n = 40$, then search volume increases 10^6 times with the consequent time costs.

There are many ways to solve this problem. The first is using of algorithms for solving integer programming problems, such as, for example, the Dancing algorithm or sequential unit assignment algorithms [6]. The second is increasing the speed of the computing system through the using of multiprocessor technology and parallelization of computing. Here, the value of the objective function for each feasible solution can be calculated on a separate processor with subsequent comparison of the results, and you can use parallel processors to calculate the objective function of one feasible solution, while simultaneously performing all the products included in it.

If multiprocessor (Elbrus, USSR, etc.) and vector conveyor (CRAY, USA) computers were used earlier only for large-tech calculations, now «multiprocessor» has become available to the average user. There are a large number of parallel algorithms for solving different mathematical problems [7], and methods have been developed for automatic parallelization of sequential programs, both its cyclic sections and acyclic ones [8].

Also, in recent years, artificial neural networks (ANNs) have become an important research tool in various fields of life [9–11], which are represent computing technology.

A significant part of the new results in research areas such as computer graphics, speech and image recognition was obtained using neural networks [12–14]. Based on neural networks, new approaches to the study of dynamic problems in the sphere of economics are being developed [11].

2 Materials and Methods

It's proposed to use artificial neural networks (ANNs) for solving such problems of economics and management, where the formalization of the decision stages is either complicated enough or even impossible. Well-trained on a limited number of data ANN can show quite reliable results for data that weren't used in the learning process. At the same time, a large number of interneuronal connections and using of a graphics processor can't only significantly accelerate the learning process due to parallel processing of information, but also ensure the processing of new data in a time close to real.

In the area of economics (and not only economics), ANNs are actively used to predict time series. The possibility of using ANNs to solve these problems is determined by several theorems of mathematics: the Tackens theorem, Gorban's theorem, Kolmogorov's theorem and its refinement.

The analysis of the time series generated by some dynamic system is carried out with the aim of predicting the values of its subsequent states on the basis of the available data on its previous states. It has been proved [15] that there is a so-called «immersion depth», which, based on some function of several variables, ensures the uniqueness of such a prediction. That is, there exists a function that is clearly independent of:

$$x_{k+1} = \varphi(x_k, \ldots, x_{k-n+1}). \tag{1}$$

Based on this fact, the problem of forecasting the time series can be reduced to the problem of approximating the (best) nonlinear function of several variables.

For approximation, data sets are used that are obtained as a result of certain measurements (analysis of the history of the time series).

The nonlinear model that is used to solve the problem of forecasting the time series x_k, $k = 0, 1, \ldots$ has the next form:

$$\tilde{x}_{k+1} = f(x_k, \ldots, x_{k-n+1}). \tag{2}$$

Here the function $f(\cdot)$ is a certain nonlinear function of several variables, $\tilde{x}_{k+1}$ is the predicted value of the series, $x_k, \ldots, x_{k-n+1}$ is the observed values, and n is the order of the model.

The Gorban theorem [16] shows that if a nonlinear twice continuously differentiable function is selected as the activation function of neurons, then any function continuous on a closed bounded set can be uniformly approximated by the functions that ANN calculates.

One of the most commonly used neuron activation function is the logistic function (sigmoid)

$$g(z) = \frac{1}{1 + e^{-\alpha z}}. \tag{3}$$

The choice of this non-linear function with saturation is determined by its following properties: firstly, it amplifies weak signals more than large ones, which prevents saturation from large signals (gentle slope of the logistic curve), and secondly, it has a simple expression for its derivative

$$g'(z) = \alpha \cdot g(z) \cdot (1 - g(z)). \tag{4}$$

Other neuron activation functions, such as hyperbolic tangent, are also considered.

The ANN, which will be used to predict time series, should be a function f of two vector arguments: $f(X, W)$, where $X \in \mathbb{R}^n$ are the input parameters and $W \in \mathbb{R}^m$ are the internal parameters (weights).

Neural network training can be carried out with a teacher, which implies the presence of a target vector y_i, which known for each input vector X_i, that is, a

vector that is expected to be output. If training is conducted without a teacher, the significance of the target vector isn't known.

In the process of training a neural network, the vector of internal parameters W is selected so that for all row vectors X_i of the training matrix X the next condition is carried out:

$$y_i \approx f(X_i, W). \tag{5}$$

The next function often uses as error measure of such an approximation:

$$S(W) = \sum_i (f(X_i, W) - y_i)^2 \tag{6}$$

which should take the smallest possible value.

The vectors X_i of the training matrix X are sequentially succumb to the input of the ANN, which calculates the corresponding output vector $f(X_i, W)$, compares it with the target vector, and calculates the error. If the error doesn't satisfy the error criterion, the value of the internal parameters is adjusted by applying one of the manually selected algorithms to minimize the error function $S(W)$. The same input vector can be supplied to the input with a certain frequency as many times as required for the minimization algorithm to work, because of the fact that the internal parameters of the ANN are adjusted in such a way that the error over the entire training array corresponds to the required level.

Various methods are used to minimize the error function. For example, in the popular TensorFlow neural network computing package [17], ten methods are standardly used (tf.train.GradientDescentOptimizer, tf.train.AdadeltaOptimizer, tf.train.FtrlOptimizer, etc.), which are all varieties or modifications of the gradient method. Nine of them can be considered optimizers of the basic gradient descent algorithm (GradientDescentOptimizer), they were created in order to increase the effectiveness of training.

If we consider the basic method of gradient descent (GradientDescentOptimizer), then one step with a given learning speed (LR, Learning-Rate) means the transition from the vector of internal parameters W_0 to W_1:

$$W_0 \to W_1 = W_0 - LR\frac{\nabla S}{|\nabla S|} \tag{7}$$

where ∇S is the gradient vector of the function.

Along with function (7), the Kullback Leibler distance is widely used, associated with the maximum likelihood criterion:

$$E(W) = \sum_i \left[f(X_i, W) \cdot \log \frac{f(X_i, W)}{y_i} + (1 - f(X_i, W)) \cdot \log \frac{1 - f(X_i, W)}{1 - y_i} \right]. \tag{8}$$

In this case, one step with a given learning rate (LR) means the transition from the vector of internal parameters W_0 to W_1:

$$W_0 \to W_1 = W_0 - LR\frac{\nabla E}{|\nabla E|} \tag{9}$$

where ∇E is the gradient vector of the function.

In addition to those described, there are a large number of options for choosing the error measure and ways to minimize it [11]. The choice of the error measure largely depends on the complexity of the task, the solution of which requires training of the ANN, and on the features of the ANN architecture that will be used for training.

At the training stage, which, in general, is the bottleneck and impedes using of neural systems for solving problems in the area of economics, various kinds of problems may arise: the training lasts for a very long time or stops without reaching a result; a local rather than a global minimum of the residual function was achieved as a result of the training, etc.

To avoid such situations, it's necessary to pay special attention to the choice of the initial value of the internal parameters (weights) W_0, apply random ordering of the training sequence of vectors, pay attention to the choice of learning speed. You can also control the magnitude of the learning step, use the impulse method and increase the value of the sigmoid derivative (sometimes multiplying by 0.1).

The most important indicator of ANN training is the convergence rate of the selected method. If the parameter LR (learning rate) isn't chosen too large, then it can be calculated that the error value (objective function S) will uniformly decrease with each step of the method. To measure the effectiveness of a step, you can use:

$$q = 1 - \frac{S_1}{S_0}, \tag{10}$$

where S_0 is the value of the objective function at the beginning of the step, S_1 is at the end. If the efficiency turns out to be negative, it would mean that the objective function at this step did not decrease, but increased, and perhaps in the learning process we slipped the global minimum.

3 Discussion and Results

It turns out that in order to solve the problem of forecasting the time series based on the ANN, it's necessary to solve the mathematical problem of interpolating the nonlinear function of several variables using data sets obtained from the analysis of the history of the time series. It's clear that the process of solving this problem takes place in several stages. The following scheme is proposed for the phased construction of the ANN, which determines the main characteristics of the ANN, the correct choice of which will qualitatively solve the task of forecasting the time series.

- Firstly, an analysis is made of the history of the series under study. The purpose of this analysis is collecting data that will be used for training and to normalize it.
- Preparation of the collected data, namely their random ordering, dividing, if it's necessary, into blocks, etc., that is, carrying out procedures that could speed up and improve the learning process.
- The choice of architecture of the neural network (the number of input neurons, due in particular to the «immersion depth», multilayer, the number of neurons in the layer, direct propagation or bidirectional propagation, connectivity, etc.).
- Selection of qualitative characteristics of the neural network and training parameters. It's necessary to select the neuron activation function, the error function and the algorithm that will be used to minimize it, select the initial value of the internal parameters and the learning speed of the NS, so that its quality training is ensured.
- Direct training of the neutron network and further verification of its compliance with the studied time series on data that weren't used for training, with subsequent adjustment of the parameters if the learning results were unsatisfactory.
- The final training and memorization of the ANN with the aim of its further use for predicting the studied time series.

Analyzing the proposed scheme, we can draw a disappointing conclusion.

The fact is that the main part of the procedure is the selection and training of a neural network, which requires an assessment of all the possible architectures of neural networks and the methods of their training.

Iterative algorithms of local optimization are usually used to train ANNs.

You can use algorithms that calculate partial derivatives of only the first order, or algorithms that calculate partial derivatives of the first and second orders.

Using of stochastic methods also gives in some cases good results for training ANNs. This applies equally to random search and the Monte Carlo method.

The global optimization algorithms, which are based on enumerating the values of internal parameters on which the objective function (error function) depends, are less commonly used [9–11].

Since there are still no criteria for confidently choosing the right «methodology» for training a neural network, the high-quality solution to the problem requires the help of a mathematician and programmer, and this means that relying on the full use of the ANN to solve the problems of the economy is possible only if economists attract certain knowledge in the field of mathematics.

There is no sense to reduce the solution of all problems in the area of economics to the use of neural networks, even by well-trained ones. It's very important to take account of different factors while choosing a solution method. To predict well-structured time series, which can be defined by difference equations, there are various mathematical methods that are less time-consuming compared to training neural networks and don't require specially equipped computing techniques. What else can be attributed to the lack of a neural network?

Firstly, it's the lack of the possibility of a qualitative analysis of the problem being solved. Using a neural network is a purely quantitative method. He can give a correct

forecast if the network is well trained, but doesn't imply a qualitative analysis of the influence of changes in model parameters on the dynamics of the process (here we aren't talking about weights, but about various factors of the process, the change of which can significantly affect its dynamics).

4 Conclusion

The idea of using neural networks at this stage in the development of the digital economy isn't to supplant traditional methods, but to try to expand the range of tasks. Today, neural networks can be effectively used to predict events if they are generated by endogenous factors.

If the data don't reflect changes caused by exogenous factors, then the neural network is powerless in predicting changes in the future. It can be assumed that further study of neural networks and the development of a selection criterion for the training method will lead to more advanced methods for training ANNs, which means its wider using.

Priority of Public-Private Partnership Models in the Conditions of Digital Transformation of the Russian Economic System

Valentina N. Parakhina, Olga A. Boris, Galina V. Vorontsova, Oksana N. Momotova, and Rustam M. Ustaev

Abstract The article substantiates the relevance of the study of approaches to evaluating public-private partnership (PPP) models, taking into account the digital transformation of the economic system taking place in Russian society. A retrospective analysis of the use of PPPs in the Russian Federation (RF) and the EU countries has been carried out, reflecting an understanding of the essential role of public-private partnership, primarily in the implementation of major infrastructure innovation projects in the context of digital transformation of social development processes. It is noted that in foreign countries, public-private partnership has been actively used over the past decades to create and implement various types of innovations that require significant long-term investments, such as developments in the field of robotics and artificial intelligence. The article identifies problematic issues that reduce the effectiveness of public-private partnership in the Russian Federation, regardless of the choice of a particular model of project implementation: gaps in legislation relating to the regulatory regulation of PPP projects. The efficiency of the main PPP models is also analyzed, and a comparative description of the costs of digital transformation of the Russian economy by sector is carried out. The results of the study are summarized, which make it easier to choose a PPP model in the sphere of digitalization of the economy.

1 Introduction

Today is a time of rapid development of information, telecommunications, scientific, technical and digital technologies, an era of change. Every day, each of us in one way or another interacts with the indicated realities of our time. Regardless of the professional specifics of the activity and industry affiliation of the economic system, each of its employees communicates, provides vocational training or retraining, performs their duties, uses the workflow system, using various electronic devices and gadgets that are accessible even to small businesses, thanks to a scientific breakthrough in the field of digital technology. Achievements of the digital economy simplify our life, taking it to a new, innovative level. Any transformations taking place in economic systems require serious efforts to adapt to new realities. It should be noted that these processes make it necessary to update the methodological framework of public-private partnerships (PPP) as one of the modern economic and legal phenomena of our time, which allows us to efficiently accumulate and use the resources available to private business and the state to successfully undergo the digital transformation of the Russian economic system.

2 Methodology

Following global trends, Russia is experiencing a rapid digital transformation of the economic system that has developed in recent decades, affecting a large number of spheres of society. The ongoing digitalization of the economy, the rapid growth of IT-technologies, the spread of innovations based on artificial intelligence necessitates the use of various forms and methods of managing economic systems aimed at the optimal use of available resources in the country.

The digital transformation of the Russian economy requires the accumulation of significant financial, organizational, intellectual resources, which is possible with a properly organized partnership between government and business, with the progressive development of public-private partnership institutions.

The public-private partnership toolkit includes, first of all, the forms, methods, and financial models of PPP projects.

The issue of classifying forms of public-private partnership in modern domestic and foreign administrative literature continues to be debatable. So, various researchers justify the appropriateness of using many classifications of forms, models, types and types of PPPs.

The study was based on the theoretical and methodological foundations of public-private partnerships, described in the works of the following foreign researchers: Bowf P, Karlof B, Keynes J, Coase R, Porter M, Prusak L, Rol M, Samuelson P, Smith A, Frank B, Friedman M, Sharp W, et al.

The methodological basis of the study was also the work of Russian scientists: Abalkina LI, Varnavsky VG, Zvereva AA, Makarova IN, Malgina VA and etc.

In questions of studying PPP tools, special attention is paid to the views of the Russian researcher M. Deryabina

3 Results

Under the partnership between the state and business it is customary to understand the form of organization of state power and private business, the purpose of which is to create and implement specific projects that have socio-economic significance for a specific economic system, which can be implemented through the development of strategically important sectors and spheres of the economy, infrastructure development and the provision of socially significant services to both the population of the whole country as a whole, and its individual territories [1].

As for digitalization, digital transformation or digitalization, there is a widespread understanding of this phenomenon as a process of transition of the entire economy as a whole, or its individual components to a new innovative level, the essence of which is the use of information and digital technologies, which serve as the basis for further improvement of business processes [2].

Consider the key objectives of the digital transformation of the Russian economy:

- creation of a unified architecture of the state digital platform;
- transfer of all public services to electronic form with a remote biometric identification system;
- digitalization of control and supervision and licensing activities;
- introducing a model of a service state—the culture "state for me," which implies a proactive offer by the state of online services to meet the needs of citizens and businesses;
- development of civil servants understanding of digital reality, the formation of competencies in the field of digitalization, digital skills. [3].

It should be noted that the development and application of the PPP institution is gaining momentum all over the world. The accumulated experience in the implementation of PPP projects confirms its undeniable effectiveness for the modernization and transformation of national economies of various countries. So, often in cases where the state has a budget deficit for several reasons or the country experiences an economic crisis, private investment acts as an additional source of financing for the implementation of various state goals and objectives. In turn, the private sector of the economy acquires in this case the opportunity to carry out such activities for the

production of goods or the provision of services, which had previously been monopolized by the state (and with the benefits and various measures of state support) [4].

It should be noted that in the period of the digital transformation of the economy, large-scale tasks have been entrusted to public-private partnerships, which allow accelerating the development of the intellectual, scientific and technical progress of a particular economic system. To do this, the state often attracts private investment, uses the accumulated experience and competitive advantages of a commercial business partner, without which it is difficult today to implement large-scale innovative projects [5].

Note that the experience of using the PPP institution in developed foreign countries allows us to conclude that there is a direct correlation between the level of development of PPP projects and the rate of creation and implementation of innovations in a particular state. So, one of the fundamental moments in the development of the digital economy—development in the field of robotics, scientific and technological innovation and the creation of artificial intelligence—in foreign countries is largely based on the cooperation of the state with private business. For example, in the European Union (EU), about 190 million euros were allocated to implement projects in the form of public-private partnerships for the Horizon 2020 innovation program, about 700 million euros were invested in the EU Member States in the SPARC program, and 2.1 billion euros in private business creation of industrial robotics. As we can see, European countries are actively using the PPP institution to develop the digital economy, investing substantial organizational, material and financial resources in it. Moreover, private business is actively involved in this process, offering ever new opportunities for the development of digitalization. It should be noted that in the EU countries the development and creation of computer equipment and the latest high-tech developments are also based on large-scale cooperation of the state with the private sector of the economy [6].

It should be noted that at present in Russia the volume of private investments in PPP infrastructure projects is less than 1% of the gross domestic product. Practice shows that for the effective development of the PPP institution, this indicator should be 4–5% of GDP [7].

As for the Russian Federation, unfortunately, in many sectors of the economy, the technical and digital base used is obsolete, which negatively affects the efficiency of social production processes, a decrease in labor productivity, and an unjustified increase in the cost of goods and services rendered. For example, in many enterprises of the Russian Federation fixed assets and technical devices that have obsolete are functioning, which inhibit the production process, require a large number of energy costs of working personnel and lower the quality and quantity of manufactured products. This is due to a shortage of funds for the digital and technical transformation of the economy. In addition, it is necessary to note the negative impact of certain geopolitical processes that reduce access to the global financial markets and reduce foreign investment required for the digital transformation of the domestic economy under pressure from sanctions and other restrictions. It is in connection with this

that public-private partnerships are a significant tool in the digital, scientific and technological transformation of the Russian economy.

It should be noted that government spending (10, 8% of the total cost) for the development of digitalization in the Russian Federation is significantly lower than the costs of the private sector (entrepreneurs—40.4%, non-profit organizations—0.7%, households—36.4%, the costs of organizations and households for the acquisition of digital content—11.3%) (Fig. 1) [6].

Thus, domestic private business demonstrates a great interest in the digital transformation of its industries.

State authorities are experiencing a shortage of financial resources for the necessary measures to digitalize the country's economy. In this regard, the state often attracts private investment to implement large-scale projects, since it does not have its own resources (or cannot afford to ignore other items of expenditure in terms of their socio-economic significance).

Note that the process of digital transformation of the Russian economy has identified the need to improve the methodological base of PPPs:

– in the search for various forms and models of PPPs that would ensure the effective implementation of innovative projects in the field of digitalization;

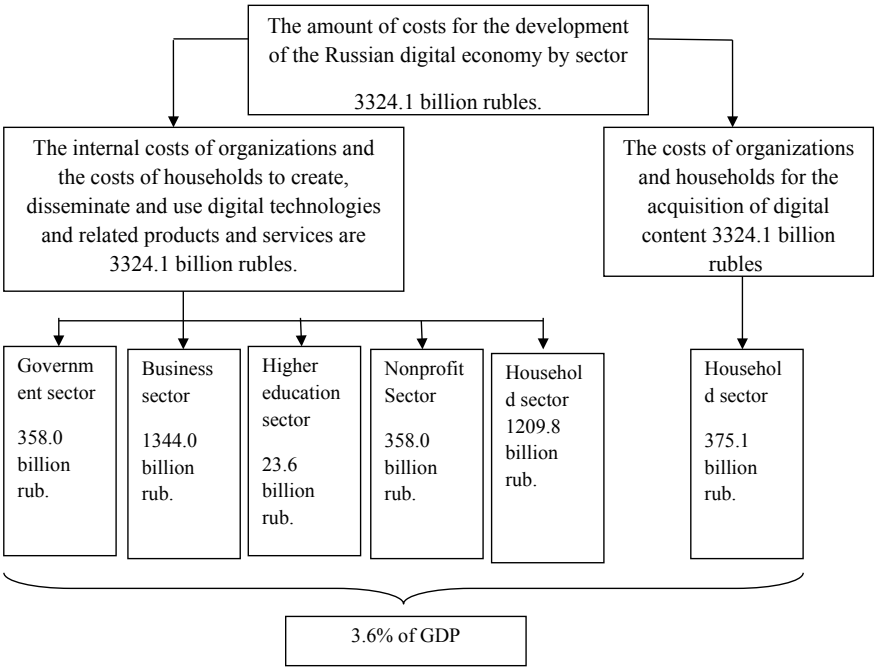

Fig. 1 The structure of domestic costs for the development of the digital economy by sectors in 2018

Table 1 Models, forms and mechanisms for the implementation of PPPs in the Russian Federation (RF)

Models	Forms of incorporation	Mechanisms (legislative base) for implementation
Organization model	Special economic zones, technology parks, technology cities, clusters, investment and venture funds, etc.	Normative legal acts of the Russian Federation (Civil Code of the Russian Federation, Tax Code of the Russian Federation, Federal Law (Federal Law) of July 13, 2015 No. 224-FZ, Federal Law of July 21, 2005 No. 115-FZ, Federal Law of December 30, 1995 No. 225-FZ, Federal Law of April 5, 2013 No. 44-FZ, Federal Law of July 18, 2011 No. 223-FZ, Federal Law of July 26, 2006 No. 135-FZ, etc.)
Capital participation model	Businesses with mixed public-private participation, joint ventures, state corporations	
Contractual models	Concessions, production sharing agreements, government contracts, lease agreements with investment obligations of the private sector, life cycle contract, etc.	

– in the development of the approaches used to evaluate public-private partnership models in the context of the digital transformation of the economy [8].

Table 1 shows the main models, forms and mechanisms for implementing public-private partnerships in the Russian Federation [9].

In contrast to the above point of view, the researcher Gracheva M.L. He proposes to distinguish PPP instruments as: state contract, concession, leasing agreements, investment agreements, the creation of joint ventures and build specific models of PPP projects depending on its specifics. So, in the field of innovation transfer, which serves as the basis for the digitalization of the economic system, it is proposed to use two models: one based on the transfer of the right to use the developed intellectual property based on a license agreement and a model for creating a joint venture, the advantage of which is the fair distribution of risks between the investor and the state [10].

It must be noted that in the domestic scientific literature there are certain gaps in covering the issue of the forms and models of PPPs that would be most effective in the context of the digital transformation of the Russian economy and cooperation between the state and business in the field of innovative PPP projects.

So, based on the current Russian economic policy and the views presented in the writings of Russian authors, it can be considered the most acceptable forms for the implementation of PPPs in the field of digitalization of the agreement on the creation of special economic zones, technology parks, clusters, technopolises, business incubators, etc. forms of cooperation between the state and business are specifically aimed at the development of innovative and scientific-technical sectors of the economy [11].

When implementing digitalization projects, a number of authors consider the predominant use of such a form of PPP as a concession, while the most appropriate models are identified within the framework of the contract model:

BOOT (construction—ownership—operation—mandatory transfer);
BOT (construction—operation—transfer).

A positive aspect is the emergence of a PPP model based on the development of alliances in the implementation of large-scale innovative projects with the participation of a number of large institutional organizations. The main institutions of PPP in the Russian Federation can be considered the Russian Venture Company JSC (RVC JSC)—the state fund of funds and the venture capital market development institute of the Russian Federation and the Skolkovo Innovation Center, which are key platforms for the development of innovative technologies in Russia [12].

At the same time, Russian and foreign researchers believe that for PPP projects in the above-mentioned field, such models as the exchange model focused on a specific object and the "pool" model, the essence of which is the creation of institutional partnership or long-term cooperation, are also effective.

As for the first of these models, here the state and private partner pursue a common goal—the development of innovative products that they seek to obtain in the course of cooperation. In the second case, the alliance of business and the state is united in the so-called "pool", that is, in a joint venture for the long-term production of new products or services that are supposed to be developed in the process of a large-scale digitalization project. This type of research organization is an instrument of long-term cooperation between science and production, which quickly responds to the emergence of new goals and directions of research and is open to the perception of new ideas in the field of digitalization of the economy. A private partner in this PPP model often acts as an investor, providing the necessary capital for the implementation of the project [13].

Of course, the PPP model used is designed, first of all, to ensure the effectiveness of the project implemented with its help. In turn, the evaluation of project effectiveness is regulated by regulatory acts of the federal and regional levels (Order of November 30, 2015 No. 894 "On approving the methodology for assessing the effectiveness of a public-private partnership project, a municipal-private partnership project and determining their comparative advantage", 2015, https://www.consultant.ru/document/cons_doc_LAW_192148/).

In our opinion, quantitative and qualitative verification of the assessment of models used in specific projects of public-private partnerships will be more accurate if it is based on data from a single information base on PPP projects in the Russian Federation, accumulating experience in the application of PPP models in various sectors of the Russian Federation economics.

To optimize the choice of forms and models of PPP for the implementation of projects in the field of digitalization of the economy, it is advisable to create a unified information system on PPP in Russia, which will accumulate the following information (Fig. 2):

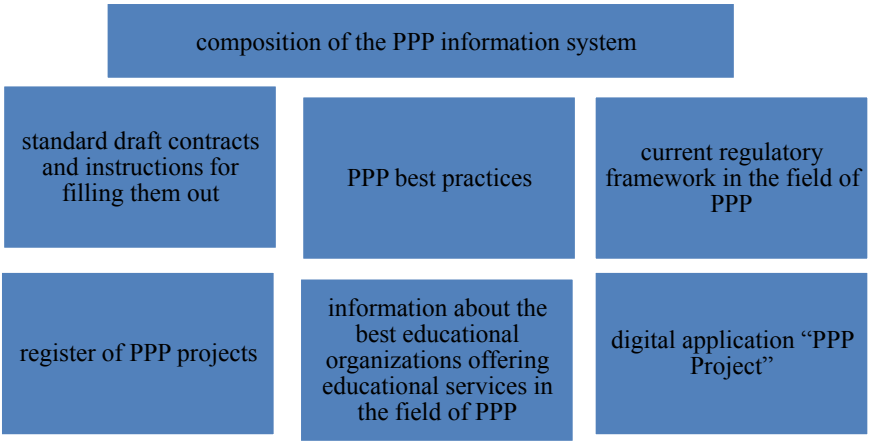

Fig. 2 Recommended PPP information system in Russia

- information on best practices of PPP;
- standard draft contracts and instructions for filling them out;
- current regulatory framework in the field of PPP;
- register of PPP projects;
- the digital application "PPP Project", which allows you to select design objects in which various regions of Russia are interested in accordance with the resources available to a private investor, collect information necessary to determine key parameters of a future project, etc.;
- information about the best educational organizations offering educational services in the field of PPP.

It should be noted that the regulatory framework for the implementation and evaluation of PPP projects has now been created in the Russian Federation: the Federal Law "On Public-Private Partnership, Municipal-Private Partnership in the Russian Federation and Amendments" is the main regulatory act governing PPPs in separate legislative acts of the Russian Federation", in addition to the specified act, it may be noted: the Federal Law "On Concession Agreements", the Federal Law "On Production Sharing Agreements", the Federal Law "On special economic zones in the Russian Federation," et al. [14].

At this stage, the PPP institution in Russia in the field of digitalization is at the stage of rapid development. However, many legal and economic issues still require refinement, which, in our opinion, will soon be allowed for the future development of PPPs.

Acknowledgements The study is performed with financial support from the Russian Foundation of Fundamental Research within the research project «Public-private partnership: models and their evaluation from the positions of development of international cooperation of Russia and Abkhazia in the modern conditions of economy digitization», project №. 19-510-40001/Abkh-a.

Digital Transformation of the Market for Investment Projects with State Participation

Fail M. Ibyatov, Vladimir B. Zotov, and Marina A. Cherkasova

Abstract The investment market with state participation is a system of partnership interaction between subjects of investment process. The paper analyzes German experience in digitalization of investment market, considers the problems of functioning of digital platform "ROSINFRA" and defines the directions of digitalization of investment market with state participation in Russia.

Keywords Digitalization of the economy · Investments · Technological changes · Government policy · Public-private partnership

JEL Classification O330 · O390 · H54

1 Introduction

The continuous and global development of digital technology over the past decades has had a growing impact on all governance processes in the public sector. The digital transformation of public administration presupposes the achievement of maximum usefulness of authorities' activities for the population [1]. Digital transformation means the development and use of new methods and models, changing approaches to management, team building, project development and management systems through the prism of digitalization [2].

As part of the digitalization of the Russian economy, integrated platform models (the State Unified Cloud Platform GEOP, the Platform for Support of Infrastructure

Projects “ROSINFRA”, the Common Government Services Portal “Gosuslugi”, the State Automated System “Management”, etc.) have been formed in the public administration system, which allow to convert all popular services into electronic form, to ensure a continuous process of data quality monitoring, to form integrated digital processes [3]. The main platform solutions are automated and do not depend on human activity. Formation of platform models assumes creation of complex infrastructure, development of interaction with commercial and non-commercial companies and citizens. The process of digitalization for the investment market, which is a system of partnership between the subjects of the investment process, is especially relevant. This is due to the lack of financial resources for the implementation of investment projects, the difficulty of finding partners and other problems on the investment market [4].

2 Methodology

The methodological basis of the study was formed by general scientific methods, among which the following ones should be emphasized: analysis, synthesis, comparison, induction, deduction, grouping, generalization, analogy. Structural and functional, as well as system methods were also used.

Modelling and forecasting have been used to justify the proposed provisions

Theoretical basis of the work consisted of the fundamental provisions contained in the scientific papers of leading Russian and foreign economists and specialists in other scientific fields. For the Russian practice, the activation of digital transformation processes acquires special urgency today.

In European countries, the public administration system is being fully reorganized and all public services are being digitized. The EU Single Digital Market, customs, logistics and financial systems of the EAEU are already functioning digitally, etc. A typical example of the successful digitization of the investment market is the platform of ÖPP Deutschland AG. In 2008, ÖPP Deutschland AG (Partnerschaften Deutschland, PD) was founded in Germany. It was conceived as a mixed capital company to advise the government on government involvement in investment projects in Germany. In January 2017, ÖPP Deutschland AG was transformed into a state-owned company—PD—Berater der öffentlichen Hand GmbH, which supports government customers in all modernization and procurement projects with a special focus on infrastructure consulting [5].

A single database was created, which is constantly being expanded and maintained by ÖPP Deutschland AG. It describes all already implemented and contracted investment projects of ÖPP with state participation in Germany [6]. In addition to searching and ranking by various attributes (cost, level, implementation time, industry, etc.), the platform allows you to search for information about the projects being implemented in each federal state. At this, with an interactive selection of the region of interest, a tab with the division of the land, municipalities and projects being implemented and planned for implementation there shows up.

In terms of the number of projects with state participation in Germany, only projects that allow the tracking of their entire life cycle are considered: site transfer, planning, construction, financing, operation. The ÖPP database also contains projects where the life cycle phase is not limited to a contractual component or is not defined. Since July 2008, this platform has been unlocked and is available to everyone interested, i.e. the system is absolutely transparent [7].

3 Results

In the Russian Federation, the state tries to actively promote partnerships in the field of investment and to strengthen its capacity for project development and follow-up [8]. In order to facilitate the launch of infrastructure investment projects with state participation, the digital platform "ROSINFRA" was created and launched in 2019 as a comprehensive digital solution that meets the challenges of time and technological development [9]. The Center for Public-Private Partnership of the Russian Federation has digitized all the information on investment projects with state participation accumulated over the last 10 years and formed a database, and then an information platform for the formation and implementation of projects was created on its basis. Any user of the platform can work in a personal profile, customizing it to their needs. The "ROSINFRA" platform is a full digital project office for investment market participants.

The "ROSINFRA" platform is designed to facilitate communication between participants of the market of investment projects with state participation through the launch of services that allow: quick and convenient exchange of experience, successful practices and attraction of experts for the preparation and implementation of projects online, to select the optimal characteristics of the project with the help of a "structurizer", to evaluate its effectiveness, to organize convenient interaction between members of the project team, experts, authorities among themselves, to find a partner for the preparation, launch and implementation of projects. At present, the platform provides a description of almost 3,500 investment projects with state participation, more than 1,200 companies of investment market participants are registered, the total volume of investments is almost 2.4 trillion rubles, and there are many analytical, methodological and legal documents [9].

The platform is actively developing, however, there are certain problems of its functioning, including: lack of experience and low awareness of the investment market of existing practices and opportunities; difficulty and cost of attracting qualified experts to prepare projects; difficulty in finding contractors; low awareness of what is happening in the market; slow updating of legislation and by-laws of departmental regulations; inaccessibility of most projects for small businesses, etc. [1]. In order to further digitalize economic processes, the IT industry should be promoted, progressive technologies in innovation should be created, and international cooperation in innovation development and implementation should be strengthened [10]. It seems necessary to digitize the cooperation between business and the state, to

increase investments in programs of complex digital transformation of the investment market, to create an investment environment that is comfortable for business and at the same time meets the interests of the state.

4 Conclusion

Taking into account new trends in digitalization, the attention of the state to the activity of users of digital resources has increased. It is necessary to activate the interaction between different departments of public administration authorities and to reorganize the relations of all levels of public authorities into digital format. At the same time, the degree of state control over digitalization of the investment market should not go beyond reasonable limits. Digitalization of public governance in all segments can and should create conditions for digitalization of the Russian economy.

Digitalization of Brand Communication as a Modern Trend

Anna A. Komarova, Elena V. Moreeva, and Elena V. Dianina

Abstract The purpose of the article is to research of directions of development and formation of conclusions based on brand management research findings. The urgency of digital technologies in brand management is defined in the work. According to the Forrester research company, by 2020 more than half of companies' revenues will depend on digital technologies. If the transformation is not started now, then it will be too late. The subject-target method, statistical and comparative methods are the methodology in the work. The study was carried out using the desk research method of statistical analysis and the field method of sampling and questionnaires. The article notes that in the conditions of modern social and economic reality, globalization processes both in the world as a whole and in the Russian Federation cause serious market transformations, including through the development of innovations: technical, technological, social. One of them is total digitalization, which becomes a determining factor of economic development in the global strategic outlook. An important conclusion was made that the modern trend of business in Russia is undoubtedly optimization and further development of brand management. The results of the study consisted in the formation of conclusions about the industry effectiveness of brand management and its digitalization.

1 Introduction

In management, including brand management, the process of systematization of the company's efforts (development of new products and services, production, finance, sales, etc.) is coordinated in the direction of achieving such important levels as general corporate strategic and operational goals, focused on rapidly changing market requirements, ensuring close and effective interaction with the external environment [1, 3, 5, 6, 8, 10, 11, 14, 15, 16].

In their works, D. Aaker and E. Yohimsteiler write that brands cannot ignore the established digital habits of their consumers, as well as the fact that modern digital technology allows companies to reach a new level of efficiency [2].

V. N. Domnin notes that digital transformation is understood as the introduction of digital technologies in all areas of business. Digital-transformation:

- fundamentally changes the way we interact with our customers, employees and business partners;
- improves business processes and eliminates inefficiencies;
- reduces the speed of management decision making through the use of Big Data;
- introduces new business models.

Huge investments are being made in digital transformation: analysts predict that by the end of 2020 they will amount to 1.7 billion dollars [9].

Such authors as E.A. Rudaya note that the most important direction of introduction and development of brand management digitalization of companies is the digitalization of FMCG (fast moving consumer goods)—an industry that has not been left out by digital transformation, although it comes in a much more complex way and the process of implementation of digital technologies is slow [13].

2 Background and Methodology

The subject-target method, statistical and comparative methods are the methodology in the work. The study was carried out using the desk research method of statistical analysis and the field research method of sampling and questionnaires.

The effective block of the research was formed taking into account modern trends in brand management and its digitalization. The calculations considered such criteria as: factors of dynamism (the impact of digital economy influences economic growth and efficiency), the formation of levels of access to digital technology (on the scale of development) and aspects of trust (by what methods and ways the market can strengthen trust in the digital economy). Such methods make it possible to assess and determine how well businesses are building the digital economy for everybody.

The research presented in this article has been carried out by means of a sampling survey method, where 112 largest Russian and foreign companies have determined what technologies modern business introduces, what budgets the organization is ready to spend on such projects and how they generally approach digital transformation management.

3 Discussion and Results

Table 1 shows the ratio of different business lines addressing different needs of customers in the world through digitalization.

Business modes and markets in this area have evolved over the years, and now efforts are required to move traditional companies' work to digital rails. Final consumers of FMCG products are ordinary people who have already embraced digital technology in their lives.

The digital transformation has already brought some FMCG companies positive results. For example, Mondelēz products are sold on digital media platforms of 25 countries. Some unique products such as Trident gum with "Star Wars" symbols on the label could only be bought online. Today, Mondelēz digital technology supports the company's global financial operations in 75 countries on 6 continents.

In two months, more than 75 million emojis were created, consumers bought 870 thousand codes on packaging worth 2.5 million dollars, and sales grew by 50% in the first five weeks after launch.

As a result of the use of digitalization in brand management of modern companies, brand portfolio management is improved, flexibility and stability of business lines are increased, the client base of companies is increased, the directions of their client orientation are optimized, the time of brand introduction to the market is reduced, resources for reinvestment in innovations and growth are increased.

The following are the tools and results of a survey of more than 100 largest Russian and foreign companies in terms of the impact of digital technologies on business development, own brand and improving economic efficiency.

Thus, the answers to the question "Does the company have a developed program for introducing a digital brand?" were divided as follows (Table 2):

The Internet and social networks have provided customers with great opportunities to search for goods and, most importantly, to exchange information between customers. The process of information exchange has changed qualitatively.

Whereas earlier information flows were oriented in one direction, vertically from company to clients, now there is horizontal information exchange when clients exchange information with each other.

Respondents answered the question "What is the direction of digitalization of your brand?" as follows.

In Table 3 we present the ratio of Russian and European Union enterprises by types of economic activities in terms of brand digitalization.

Table 1 Ratio of different business lines addressing different needs of customers in the world through digitalization, %

Country	Basic needs	Psychological needs	Self-development needs	Social needs

Source [4]

We see that the highest level (52%) of the indicator is at the enterprises in the sphere of informatization and communication.

"Rostelecom", the largest provider of digital services and solutions in the country, presents annual monitoring of global digital trends. These fundamental studies identify, rank and systematize the most relevant and advanced digital technology systems in their continuous and dynamic development.

All data obtained as a result of surveys are subject to mandatory verification and filtering based on information about patenting and investment processes in the implementation of technological startups.

This can allow for the structuring of the most promising digital technologies and solutions that are in the focus of scientists and developers, and that actually attract sufficient and timely funding for the development, implementation, possible refinement and commercialization of digital ideas.

In the survey to the question "What obstacles do Russian companies face in implementing innovative technologies, including the digitalization of the brand?" the indicators were distributed in percentage ratio as follows (Table 4).

Table 4 Obstacles to the implementation of innovative technologies in Russian companies, including brand digitization[a]

	Characteristics	Indicator, %
1	Lack of competence	58
2	Lack of sufficient budget	32
3	Insufficient process maturity/low automation level	64
4	Low level of IT literacy of employees	35
5	Lack of necessary infrastructure	35

[a]Note respondents could select multiple answers
Source [4]

4 Conclusions

The study showed that current trends have significant consequences for advertisers and companies in terms of their interaction with users in digital channels. However, many private CEE companies are still in the early stages of digital transformation.

So, among the most important indicators of the conducted survey, we can name the following. 63% of those surveyed stated that their companies have developed or are in the process of developing digital transformation programs, but in reality it can only represent a set of short-term project directions. 77% of companies-respondents expect to increase operational efficiency and reduce costs through digitalization of management processes, production management, brand management, etc.

Among the most popular digitalization technologies tested by Russian companies are: Big Data analysis; predictive analytics (68%), chat bots (51%), office robotization (50%).

Only 16% of companies have a CDO (Chief Digital Officer) position and 13% have a digitalization committee. In most Russian companies, decisions on digitalization projects are made through individual review at the top management level. 65% of companies engage startups to implement pilot projects.

In 2020, 36% of firms have shown willingness to participate in investing and implementing project ideas in the direction of brand digitalization, the volume of investments is more than 100 million rubles, while 55% of respondents include in their plans possible costs for the brand digitalization and its management at least 50 million rubles. 51% of organizations assume that investments in the digitalization of brand processes will pay off in less than 2 years, and another 43% plan to return the investment funds within 2–5 years.

The survey concluded that more respondents (68% in the countries surveyed, 59% in Russia) say that due to the digitalization processes, including brand management, they will definitely improve the quality and efficiency of business process design and digitalization.

Almost half of those surveyed in CEE (27% in Russia) identified digitalization processes, including brand digitization, as a tool for analyzing data in the course of providing specialized products and services and holding events that increase customer loyalty and strengthen customer focus.

According to the results of the surveys, it was found that 35% of respondents in CEE (Russia—33%), express their attitude to digital branding as promising. In their opinion, a system of complex digital solutions will make it possible to bring their actions in maximum compliance with the expectations of customers. Obviously, the choice of the right approach in implementing digital brand management and its managements using means of digital technologies is an actual but rather complicated task.

As a result of the survey, we found that quite a large number of Russian CEOs consider the digitalization of their brands to be the most important technical means of solving crucial issues (for example, in terms of increasing efficiency in creating relevant supply chains).

When including digitalization in the overall development strategy of companies, it is really important to develop timely and comprehensive measures for the gradual digitalization of brand, technical processes, advertising, etc. to achieve greater economic benefits for firms. This is especially important in a situation of economic crisis, which requires companies to review and adjust their strategies, reorganization and renewal directions in order to prepare for the transition to a growth strategy [7].

CEOs of private companies are aware of the importance of digital brand management for the future of their business. This will enable the company not only to survive in an increasingly aggressive competitive environment, but also to take a leading position. One of the undoubted trends is the growing segment of online shopping, where the undeniable leader is the youth. However, the share of mature people shopping online is also increasing. Retail faces the challenge of people ceasing to perceive shopping as entertainment, spending weekends on it and wandering leisurely through the shops in search for necessary food and clothes.

This change in consumer behavior, on the one hand, is a consequence of the development of digital technology—there are convenient services, applications for smartphones, that allow to order products and goods at home quickly and even with free delivery. On the other hand, such changes continue to encourage companies to provide ever-increasing digitalization, ensuring such a transition to digital interaction with customers, where the consumer sees not so much the product as its image, successfully created by marketers. Some retailers are already closing down a number of retail stores and making them warehouses to store goods to be ordered online.

There are no stoppages in this movement of companies, as competitors are also investing heavily in promoting online platforms and digital communications with consumers. At the moment, if a brand is not online, it seems to fall out of the general rhythm of life.

Management Culture and National Mental Attitudes in the Digital Era

Valeriy D. Didenko, Larisa V. Filindash, and Nur-Akhmet Dosmukhamet

Abstract The article deals with the problem of the dependence of the management culture on the basic features of the national mental attitudes in the context of globalizing telecommunication systems. Findings. 1. Multidirectional globalization and localization of cyberspace as an environment for intercultural communication lead to the addition of opposite codes of managerial strategy in companies of countries representing various cultural and historical types. 2. The opposite philosophical concepts on the subject-matter of spiritual culture are historically expressed by two different trends such as objective-personalistic (from Protagoras to Berdyaev and Sartre) and objective-idealistic (from Plato to Hegel). 3. The content of terms "culture" and "national mental attitudes" given in the context of the spiritual life of the person and society explain the capacities of focusing his spiritual life on his own self (inner immanent-personal world) or commitment to the outside world (transcendental intention). 4. Various expressions of the spirit intentionality in eastern and western cultural traditions allow grasping the meaning, purpose, and borderlines of a person's creativity, including managerial work. The West believes in the activity of the person, but the East states the principle of non-action. Russian self-awareness absorbs the inherent features of Eastern and Western spiritual culture, which can serve as the foundation for a New Eurasian civilization aimed at the synthesis of spiritual values, worldviews, and ways of life in the East and West. 5. The conventional principles of China's managerial culture are exercised by Chinese telecommunications company Huawei Technologies, which altogether intensively adapts Western innovative strategies of management. The dual character of the contemporary managerial model in China is consistent with the dialectic of dichotomies of Chinese thinking,

1 Introduction

The problem of the interdependence of the economic and spiritual areas of the society's and man's life is foregrounded in the era of the technological revolution of the late nineteenth—early twentieth centuries.

A breakthrough of our times was the advance of the worldwide web, the transformation of E-mail, search platforms (Google, Yandex, etc.), and social networks (Odnoklassniki, Facebook, LinkedIn, etc.) into a universal indispensable source of information and the link of unlimited communication between people from different countries, continents, hemispheres.

The globalization of telecommunication systems dramatically changes all public areas (economics, politics, culture, education), invests socio-cultural communications with a new meaning, and affects the worldview of society and man. The arranged and analytically processed information obtained through the communication of population and civil officers in the digital environment serves as the basis for the production of innovations in the management culture of all the tiers, from state to commercial one. Dynamic economic changes in the world require the apprehension of the production, technological, and managerial innovations of other countries, their adaptation in terms of the national mentality foundations, and agile implementation into domestic practice.

2 Methodology

In the course of the research, we have used a systemic, comparative-typological, diagnostic, and descriptive method with elements of comparison and determination of quantitative and qualitative parameters of managerial discourse. Besides, the authors relied on comparative and typological methods to reveal similarities and differences in mental preferences affecting the management culture in different cultural and historical types of society. Using the logical and epistemological analysis allowed

introducing the relevant terms such as “national mental attitude”, “core of culture”, etc., as well as some categories of Confucian and Taoist discourse.

3 Findings

3.1 The Problem of Objectifying the Interlinkage Between National Mental Attitudes and Management Culture

The communication space of the Internet, uniting many countries and creating a single automatically operating area, a common set of language symbols and signs promotes the globalization of cyberspace as an international cultural environment. At the same time, growing trends of unification and glocalization of intercultural communication processes lead to the combination of opposite codes of managerial strategy in companies of countries representing various cultural and historical types. In this regard, we cannot but take into consideration the problems of managerial discourse arising and persisting within and based on a certain national mentality as an entirety of values, rules, and cultural traditions of a particular ethnic group.

Culture as a complex structural formation is embodied in national-ethnic forms (meanings, rules, symbols, norms, religious beliefs, social and psychological attitudes) that make up the system of social values defining the unity and integrity of spiritual life and representing the core of culture and forming the national mentality [1]. It is the identity of ethnic group, mental preferences, the way of life perception, view of the world and life express the spiritual intentions of society.

As for the management theory, the above fundamental problems are explicated in an equally important issue of determination, the influence of a national character and spirit on the quality, level, intentionality (orientation) of management culture, and variety of structure and functions as a representation of diverse national and ethnic worldviews (natural and social).

These issues, which are of great theoretical and practical importance, have been studied by domestic and foreign scientists of different domains. Mainly economists, sociologists, psychologists, ethnographers, historians like I.V. Groshev, A.V. Kolesnikov, A. Ya. Kibanov, D.K. Zakharov, V. O Konovalov, E.G. Mall, F. Kluholm and F. Strodberg, R. Quinn and K. Cameron, H. Mackay, D. L. Lewis, D. Jager succeeded in the exploration of management culture. However, the proceedings of N. A. Berdyaev, P. A. Sorokin, N. O. Losskiy, I. A. Il’ in, N. S. Trubetskoy, L. N. Gumilyov et al., which became classical philosophical studies on national character and spirit were not projected onto the examination of creativity and management.

Meanwhile, as it seems to us, it is the philosophical-worldview approach that has significant heuristic potential in the study of the specific features of managerial creativity within the particular ethnocultural community (Russian, English, Italian, Chinese, etc., and more broadly—Eastern and Western cultures).

3.2 The Contrasts of Philosophical Concepts of Spiritual Culture

In the history of philosophy, there are two opposite trends in explaining spiritual essence. An objective-personalistic trend (from Protagoras to Berdyaev and Sartre) composed the spiritual within the close limits of the unique inner world of the person, which is utterly non-correlated with objective reality. On the contrary, an objective-idealistic trend (from Plato to Hegel) objectified the spirit, lifting it to the transcendental being of the world of absolute ideas.

But no matter how different these trends could be, they have a common link, i.e. some synthetic element (constituting component), which would be, albeit an abstract, but the unity of subjective and objective, spiritual and material. For example, in N.A. Berdyaev it is God as the Absolute with the attributes of the infinite, eternal, etc., in G. Hegel—the absolute spirit as the materialization of the absolute idea of the personal activity.

Facing this eternal philosophical and worldview challenge, we proceed from that the origin of spiritual culture is explained in the ultimate life-meaning terms of human existence as an opposition ("I am the world"; "being/life–non-being/death"; "eternal/infinite–transient/finite)"; "terrestrial–extraterrestrial/spacial".

3.3 The Content of Culture and National Mental Attitudes in the Context of the Spiritual Life of the Person and Society

The author of the typology of cultural dimensions G. Hofstede defined the "culture" with respect to cross-cultural management as a "Software of the mind" [2].

Another interpretation of this statement "culture is the collective programming of the mind" is put forward in the digital area as a set of value attitudes accepted in international society under the influence of Internet communications.

However, for the qualification of national culture, following the basic, traditionally valuable intents of a particular ethnic group remains an important factor. The critical condition for the attribution of national cultural identity is mentality (from Latin "mens, mentis"—sense, mind, intelligence), a particular set of mind, that is fundamental intellectual and emotional features common both to an individual and social community, a way of viewing the world.

By the end of the twentieth century, in scientific practice, the term "mentality" is approved as a single, essential, hard-to-measure, deep way of thinking, a source of ideology, feelings, faith. The term "cultural mentality" discovers the most fundamental cultural features grounded in the consciousness and memory of people of a particular ethnic group, and therefore the most stable. Mentality maintains the core of culture, expressing national identity in a specific world outlook.

Core culture is able to self-develop and preserve a unique identity in terms of globalization.

Ontological depths of spiritual substance are experienced by a person in existential being when facing internal (subjective) and external (objective) reality. Therefore, the essence of spiritual life, its character, and attributes, not derived from socio-historical, political, ideological, and other factors of human existence, show exactly the attitude of the person to objective being. Contingent on the vector (intention) of the spiritual life of the person or society these relations can be focused on the self (inner immanent-personal world) or be directed to the outside world (transcendental intention).

3.4 The Peculiar Intentionality of the Spirit in the Eastern and Western Cultural Traditions

Comparing the typological features of the Western and Eastern cultures, one make sure that their uniqueness hinges both on the range of social, economic, political foundations, development preconditions and the way of spiritual understanding of the opposition "I am the world", immanent and transcendental, subjective-personal and universal-common.

If anthropocentrism, rationalism, and commitment to innovation are clearly expressed in the socio-cultural trend of Western mentality, then cosmocentrism, theocentrism, common spirituality, retention and transformation of traditions are prevailing in the Eastern cultures, in particular Chinese.

The core of the Eastern cultural tradition is the idea of polycentric being premised on the principle of "everything in everything" and worship of the universe, and man is conceived as modus, a function of a universal cosmic entity.

It is closely connected with the key provision of Eastern culture, that is non-action (uwei), which is interpreted by Lao Tzu and his disciples not as a rejection of any action, but as a denial of selfish activity, overcoming the personal preoccupation which is inconsistent with Tao's "right path", "the absolute spirit", "the great law", i.e. the natural law of space [3].

If the uwei principle is regarded in the East as unallowed activity in relation to the universe, then the activity principle of Western civilization conversely admits the actions of the person who is transforming the reality. Hence, personality in Western culture is treated as the outcome of a person's social adaptation, while in the Eastern tradition it's nature itself, the space in all its abundance. Famous sinologist A.S. Martynov writes that "the Confucian personality has been gifted by nature, that's why the government has evaluated him as a natural gift, "talent" (Tsai)" [4].

These archetypal differences in the intentionality of the spirit of eastern and western cultural traditions give rise to a different interpretation of the meaning, purpose, and frames of a person's creativity, including management. The dominance of the transcendental vector of the spiritual life in the East leads to an understanding

of creativity as a person's contemplation and absorption of initial perfection and harmony of cosmic life. The Taoist or Buddhist path of cognition and activity is merging with a divine principle, assimilating a person to the cosmos through a state of enlightenment, tranquility, harmony between inner and outer. It is no coincidence that in Taoism the fundamental notion of Tao is interpreted as the universal path, the law of nature, the fate and order of the cosmos. Therefore, the person needs to learn to take heed to being, to appreciate its minutes, to live in harmony with nature, thereby accumulating life energy de transformed by him into energy qi. The book "Luchshiy Chun Qiu" shows the influence of the elements of nature on the rule and life of the people, the character of the ruler, and peculiarities of his activity according to the energy of cosmic forces [5]. Along with that M. Weber, assessing the impact of the Taoist worldview on the Chinese economic culture, specific nature of economic ethics, and management philosophy, argued that the ideas of the sovereign's non-intervention in the course of "natural laws of cosmic harmony" hide low intensity and instability of economic management"[6].

Dealing with the essential displays of the Russian worldview, the researchers mark a set of dichotomies and ambivalent properties that express the binary nature of Russian culture and identity incorporated a complex combination of inherent features of Eastern and Western spiritual culture.

This was vividly and convincingly described by N. A. Berdyaev, overcoming the extremes of Slavophilism and Occidentalism while defining the uniqueness of Russian identity as religious, messianic, the deep meaning of which shapes the features of the spiritual life of Russian society and individual.

The researcher emphasized that the Russian soul is a unique combination of oppositions. He writes "on the one hand, it's humbleness, surrender; on the other hand, it's a pity-driven rebellion striving for justice. On the one hand, it's compassion, empathy; on the other hand, the possibility of cruelty; on the one hand, it's a love of freedom, and on the other hand, it's a penchant for slavery" [7].

In our opinion, the most important thing in Berdyaev's doctrine is his brilliant intuition about the metaphysical reason of such an intentional pattern of Russian spirituality: "In Russia," he says, "two paths of world history (East and West) meet and come into interaction. The Russian nation is not a purely European and not purely Asian people. Russia is a huge East-West with the historical objective of integrating and converge these two worlds." Therefore, Berdyaev believes that "the Russian idea is one of brotherhood, community, unity of people and nations" [8].

In the modern world, in relation to Berdyaev's doctrine and in the context of open confrontation between Western and Eastern civilizations, the task of predicting the vector of further socio-cultural and economic development in Russia is particularly relevant in view of its unique civilizational distinctness. The most promising seems to be the concept being developed of the establishment of a new Eurasian civilization with a focus on the synthesis of spiritual values, worldviews, ways of life of the East and West. A representative of the New Eurasian School M. L. Titarenko supposes that we need to overcome the extremes of rationalism, borrow the advanced Western technologies in creative terms, recognize the spiritual values of the East and shift to Russian Eurasianism proclaiming the principles of symphony and unity of diverse

cultures. The researcher asserts the idea of "interaction, mutual enrichment of cultures and prevention of diversity collapse, since the forced unification of cultural values is a road to nowhere, or rather a road to the death of local civilizations, and ultimately, to the self-destruction of the human race" [9].

In this complex multi-faceted topic particular attention is attached to the interaction and convergence of national economic cultures, management systems of Russia and the East, in particular China, as historically similar, with largely the same attitudes and rules, beliefs, and values determining the economic domain.

3.5 Peculiar Features of the Chinese Management Model in the Digital Era

What are the main features of the management culture in China stemming from a peculiar Chinese mentality and archetypes of national cultural identity? Summarizing the descriptions and information contained in various sources (research materials of sinologists, psychologists, economists, cultural experts, etc.), we can list the following:

1. Traditionalism as the crucial principle of managerial culture. Perceiving and adopting all the latest developments of Western management, Chinese management theorists and practitioners design their own models of managerial activity stemming from the peculiarities of the Chinese worldview established as far back as in Taoism and Confucianism.
2. The family idea to a large extent affects the national mentality of the Chinese. The corporate culture as a family enterprise composes a single community united by trust and devotion, both in relation to the company and to each other. The culture of traditional family management finds a successful application in practice and plays an important role.
3. Self-perfection and giving peace to others are the principles of the need of self-cognition, self-control, and making peace for the team and oneself.
4. Holism as an essential feature of Chinese thinking, expressing the idea of the interpenetration of opposites, the unity of consciousness and being, the integrity of the natural and social, which is the basis for dichotomies indicating sound management strategies both at the macro (society, state) and micro level (enterprise, corporation).
5. Hierarchy, as the principle of strict regulation of the relations between management levels, based on clear segregation between the senior and subordinate levels of the management machinery and vertical coordination of all management decisions.
6. Irresistible perseverance and patience in the delivery of managerial decisions as a manifestation of the primary feature of the Chinese national character due to deep-rooted philosophical and worldview principles stemming from worship of the ancestors' tradition, legacy, and the sacred meaning of the experience, the

concept of devotion to supreme values laid down in Taoism and Confucianism and exercised by the humane rule of a good-moral sovereign.

Let's dwell on some management principles practiced by one of the most successful Chinese telecommunications company Huawei Technologies founded in 1987 that has advanced from a small private national firm to the largest international corporation with 180 thousand employees.

Deeming the main task to institute a viable, reliable, invincible company, the head Ren Zhengfei adopted the official slogan "orientation to the customer, dedication, perseverance" as a formula of the universal endless path Tao and as an expression of the concept of idea devotion: "Our mission is to enrich people's lives with the help of communication technologies and innovation"[10]. The adopted management strategies of "mattress culture" strategies (daily work in two shifts), "dead grip and pack cohesion", "bindweed" were applied in market capture measures, fight against competitors for industrial, territorial, scientific positions. The hierarchy of the staff structure like in a military organization assisted the cultivation of similar corporate army rules such as discipline, order, subordination, execution of orders, aggressiveness. Thus, we can say with confidence that the basis of the management in the Chinese company is constituted by traditional features of spiritual culture.

However, developing within digital business growing by leaps and bounds, the company's management learns the policy of adopting Western patterns of management strategies.

In international cooperation, the company chooses leading partners with powerful scientific potential in telecommunication equipment, corporate networks, and consumer electronic devices, such as Siemens, Nokia, Motorola, Telecom, as well as the largest Russian communication providers Beeline, MTS, Transtelecom. A modern feature of Chinese management that preserves family management engines is a saving monetarist policy aimed at ensuring scientific and economic independence in the future. It is embodied in the establishment of scientific bases, some kind of think tanks, operating in the Eastern and South-Eastern Asia, Europe and the USA. Another modern strategic area of Huawei's activity is an essential engagement of foreign specialists and their training within the Digital Economy program (based on Russian universities). In its marketing policy, the company employs Western developments and techniques of selling its products via social networks, an online store, and an M. Video chain. Researchers stress an interesting fact regarding the sale of Huawei products in the European and Russian markets: "If in the global promotion of the product the company's profit is distributed in the ratio of 70% (Internet channels) and 30% (conventional media), then in Russia the situation is different (40% for Internet channels and 60% for conventional ones" [11].

The modern generator of ideas and the center for their diffusion into the whole company is the electronic edition-journal "People of Huawei". Among the events providing the introduction of core ideas of the company into the collective consciousness are conventional and innovative forms, such as interactive electronic workshops and training intended both to reveal personal capabilities and attain the company's goals and aimed at role plays and business games to build professional skills.

The key management principle and middle course solution in ensuring the stable and long-term development of the company is introduced by Rén Zhèngfēi the share participation of employees and reduction of his share in the capital stock. Currently, it makes up 1.4% of 98.6%, while 80 thousand people out of 180 thousand employees are the company's shareholders.

A compromise solution on employees' profit-sharing is some kind of an additional incentive for intensive labor, motivating them to be loyal to the company and management, as well as contributing to the cohesion of the team as a community of like-minded people.

4 Conclusion

In studying the problem of the interdependence of the economic and spiritual areas of society in the digital era, we can conclude that the inherent features of the national mentality ingrained in the consciousness of man and society are preserved in the spiritual culture of the ethnical groups and affect managerial creativity within a particular ethnocultural community.

If the West is prone to innovations and activity of the person aimed at reality transformation, then in the Eastern culture, in particular China, a person is interpreted as a subject contemplating the harmony of a cosmic entity.

However, in the era of digitalization and globalization of telecommunication systems, the modern Chinese model of managerial culture exhibits a dual nature, a combination of Eastern-Western and conventional-innovative trends, which is consistent with the dialectic of dichotomies of Chinese thinking underlying holism.

Among the features of spiritual culture determining the peculiarities of the Russian economic culture, ones that are similar to Chinese like binary and dichotomous nature, the embodiment of dedication to the idea are being foregrounded.

In this regard, particular importance is attached to the concept of convergence of national economic cultures, management systems of Russia and the East, in particular China, as historically established attitudes and rules, beliefs, and values determining the economic area.

Social Aspects of the Readiness of Modern Society

Ekaterina V. Kashtanova, Rafik A. Ashurbekov, and Anastasia S. Lobacheva

Abstract The article is concerned with the study and analysis of social aspects which reflect the willingness to digitize modern society, the results of the study of the spread of digital technologies and opportunities that are increasing, therefore, are being used in various areas of public production and daily living. It is common knowledge that in order for digital technology to become more active in the service of humans, it is necessary to develop the skills and abilities of the population in mastering digital literacy and the spread of digital culture [5, 6], which significantly expands the potential for digital consumption. The aim of the article is to study the conditions created in our society to improve digital literacy and the spread of digital culture among the population, because the challenges of developing digital competencies to enhance the needs of citizens is now at the forefront and their interests in the digital economy. Study results: the concept of "digital literacy" and "digital culture" have been formulated; the authors have identified the main social consequences of the results of the use of digitization processes in society—an increase in the variety, quality and time of receiving the state electronic services at all levels, appearance of a new profession related to providing advices on digital literacy to the population, erasing the boundaries of social exclusion of certain categories of citizens, as well as improving the quality of life in general.

1 Introduction

The constant growth and use of digital technologies in all areas of human and social life gives rise to a broad interpretation of the term "digitization".

Today, there is a great deal of emphasis on digitization, in particular, digital literacy and digital culture, at all levels of management, up to the government level. It is the ability of the population to use digital products in their work and everyday life.

2 Methodology

The basis of the writing of the scientific article was the method of synthesis of scientific knowledge on the application and dissemination of digital literacy. In the process of writing this scientific article, research methods were used such as: analysis of statistics and their interpretation, systemic approach, systemization of existing views and empirical data on the subject of research, specification and formalization.

The origin of the term "digital literacy" is attributed to a journalist and writer from the United States, Paul Gilster. Electronics engineer by training, he taught at a university and later became a journalist; Gilster wrote and published a bestseller with the same name more than 20 years ago (A Global Framework of Reference on Digital Literacy Skills for Indicator [1].

In the years following the issue of the book, the concepts of "digital literacy" and "digital culture" have been expanded and filled with new and new content. Many scientific and practical developments of experts from different countries deal with the study of this concept.

In Russia, according to experts, until the early 2000s, digital literacy was understood as only one competence—knowledge of the appropriate programming language and the ability to program, that is, to create certain programs, write codes. Of course, this competence was available to a very limited number of professionals in their field. Digital technologies themselves were not as widespread as they are today, so it is perfectly right to say that digital technologies and digital literacy were a kind of professional niche accessible to the small community.

With the development of digital technologies that significantly simplified the interface of programs, the so-called software itself began to create commands following the established algorithm of action, and society in general and each person in particular, resorts to digital technology every day through the use of Internet technologies and mobile gadgets, creating systems for transferring, storing and securing your own data, making online purchases, making public services from the comfort of your home, finding the right data to use in your daily activities, getting a job, learning new knowledge, and more [12].

Indeed, today digital literacy is becoming one of the leading competencies that a modern professional should have, but at the domestic level, the knowledge of digital literacy and its components seems to be an important quality.

The official definition of digital literacy given by the UN sounds like "the ability to access, manage, understand, integrate, communicate, evaluate and create information safely and appropriately through digital devices and networked technologies for participation in economic and social life"[1].

Regional public organization "Center of Internet technologies" (RPOCOIT) defines digital literacy as follows: "it is a set of knowledge skills that are needed to make safe and effective use of digital technologies and Internet resources" [14].

Thus, we might as well say that at the present stage almost every member of society is a consumer of digital services, while imposing requirements of depth of development, breadth of access and fast speed of obtaining the necessary information or services on these technologies.

3 Results

Russia, in terms of consumption of digital services, is now at the top of the ranking; it ranks 3rd in the world rating, and these rates continue to increase. On the other hand, the digital consumption index has been declining in recent years. The RPOCOIT in collaboration with the research group ZIRCON every year since 2015 are responsible for calculating and researching the status of this issue [8].

The Digital Consumption Index is calculated on the basis of a three-tier model, which in turn is formed from almost 20 key parameters that reflect the state of three components—digital consumption, digital competencies and digital security.

This indicator provides an objective opportunity to diagnose the discrepancy in the distribution and use of digitization in Russia.

From the point of view of the social aspects of the readiness of modern society for digitization processes, the most revealing approach is the humanitarian approach that studies digital culture. In accordance with this approach, the main discourse focuses on the study of the transformation of values, behavioral models, modes of communication and social interaction, as well as the change of ideological and moral installations caused by digitization processes. In this regard, the problems of the phenomena of digital culture and the readiness of modern society, namely, changes in culture due to the spread of digital technologies, the widespread availability of diverse information, the global formation of online communities, etc. [2].

From the social point of view, one of the most important indicators of the readiness of modern society for digitization is the ability of people to adapt to the digital environment, to use the provided digital services and to use digital technologies not only in professional but also in personal life. And it is important not only to have the skills of people to use personal computers and gadgets, but also to understand the functioning of modern information systems, neural systems, smart homes and cities, as well as to overcome the boundaries of social isolation [3].

The fact that state and municipal services are accessible via the Internet is important. Federal Law No. 210-FL of July 27, 2010 "On the organization of the provision

of public and municipal services" makes it possible to receive such services online, unless otherwise provided by law.

The digitization of this sphere helps to equalize the potential of citizens of certain subjects of the Russian Federation in access to public services, speed up and simplify the procedure for their implementation.

Currently, the number of registered users on the web portal of state services has passed the mark of 100 million people. Throughout 2019, the monthly increase in the number of citizens using public services via a mobile app was 1.4 million people [9].

In active ways, the service of state services continues its development, introducing the so-called super services (a complex of proactive services), focusing on the most common life situations: from the birth of a child to admission to a university online, from the European Protocol to a digital construction. 235.7 billion rubles will be allocated from the budget by the end of 2024 for the implementation of the federal digital project "Digital Public Administration" within which super services are created [7].

The Ministry of Economic Development constantly monitors the number of coverage and quality of implementation of the online service of public services. Table 1 presents the results of one of the latest studies conducted with the involvement of the headquarters of IT-researches and expertise of RANEPA.

Table 1 presents the data on the top ten leading players in terms of the digital consumption of public services. According to the presented data, Moscow Oblast is ranked with a high rate. In this region, the level of quality of consumption of digital public services exceeds 90%. In second place was Moscow ranks second with its (89.61%. On the one hand, we can explain the situation by the fact that this central region has traditionally had the largest population, but the top ten included remote regions, such as Khanty-Mansiysk Autonomous Okrug–Yugra (84.01%) and Yamalo-Nenets Autonomous Okrug (74,51%) with a much smaller population. The

Table 1 Rating of Russian subjects based on the results of monitoring the number of coverage and quality of implementation of the online service of public services for 2018

№	Subject of the Russian Federation	Coverage range and quality of online public service sales in 2018 (%)
1	Moscow oblast	93.91
2	Moscow	89.61
3	Khanty-Mansiysk Autonomous Okrug–Yugra	84.01
4	Tula Oblast	79.56
5	Sakhalin Oblast	79.20
6	St. Petersburg	76.00
7	Yamalo-Nenets Autonomous Okrug	74.51
8	Tambov Oblast	73.85
9	Belgorod Oblast	69.66
10	Lipetsk Oblast	69.03

authors of the study note, among other factors, on the one hand, the level of funding and accessibility of public services online, as in some areas there are bureaucratic obstacles to the realization of mastery in certain services by citizens, as well as a high level of digital literacy of the population in these regions. But on the other hand, not all regions have such high rates of digital consumption. Thus, there are 85 subjects in the ranking which close the list of areas where the distribution of digital services is no more than 2%, which, of course, prevents the residents of certain regions from fully enjoying the opportunities that are currently created by the state to increase the quality of life of the population, in particular, to transfer the provision of various services by federal and municipal authorities, social infrastructure facilities into the mode of digitization.

One of the most famous projects in this field is smart city technology. It is a complex of Internet technologies, a system of all available resources of modern digital infrastructure, aimed at building a city with effective feedback, a city that has provided its residents with a multifaceted range of IT solutions on the main aspects of their livelihoods [13].

In addition, representatives of a new profession related to digital literacy—consultants in the development of digital literacy (digital curators) have appeared in these regions.

This profession is completely new both in the Russian and in the world occupational classification, and there is good reason for it—the profession itself was officially designated and approved as late as at the end of 2018; at the same time, the Ministry of Labor and Social Protection of the Russian Federation approved the professional standard of the Digital Curator. The main task of this employee is to provide advice to people who do not know how and/or have no opportunity to use digital services, as well as to help different population groups to master digital competences. Today, in our country, and not only in our country, but also abroad, digital illiteracy is mostly inherent in the older generation.

The emergence of such employees carries a socially significant aspect. On the one hand, it is manifested in the fact that young people and representatives of pre-retirement age have the opportunity to find additional employment as a digital curator, on the other hand—the use of the services of a digital curator allows older generation to exercise social inclusion and avoid isolation and alienation from the opportunities of modern society, providing the older generation with confident actions in the digital environment [10].

In 2017, in the cities of Moscow, St. Petersburg, Nizhny Novgorod, Yekaterinburg, Vladivostok and Novosibirsk VCIOM, under order of the Russian Society "Knowledge" carried out a study of the target audience of 60 degrees on digital consumption. The results of this study were as follows:

- 92% of respondents take a favorable view of modern digital technologies;
- 44% of respondents are interested in the ability to use digital technologies; in particular, they would like to:
- learn how to use your computer and gadgets (48% respondents);
- develop internet skills (37% respondents);

- acquire programming skills (2% respondents);
- gain knowledge and skills as much as possible on the Internet (1% of respondents).
- 60% of respondents feel significant problems when working in the World Wide Web;
- 83% of respondents heard about the proposed opportunities for the first time.

The authors of the study note such a pattern that the higher is the level of education in a person, the higher is the level of motivation to master digital technologies. However, the lack of knowledge is not available as a demotivating factor. Related to the availability of the order of their receipt.

As part of the Federal Project, it is planned to increase the number of trained curators to 10,000 and the number of people who will be provided with digital literacy services to 2 million people until 2024.

The next most popular among the population is the opportunity to promote their professional or personal image through social networks, which also provides unlimited opportunities for communication and business communication, positioning on professional forums, blogs and official Internet portals. One of the most famous Internet projects is the electronic referendum "Active Citizen"—a project of the Government of Moscow, which has been in force since May 2014 and allows the leadership to see the attitude of citizens to certain decisions of the government concerning the development of the capital, while allowing the citizens to influence these decisions. To date, about two and a half million residents of Moscow have joined the project, with the help of which more than 125 million decisions have been made.

The use of mobile Internet by citizens opens up a very broad perspective in terms of digital consumption.

Rosstat and the results of the analysis of the Institute of Statistical Research and Knowledge Economics of the HSE Research Institute note that currently two thirds of the population (more than 75%) and the population are more than 75%) in Russia, between the ages of 15 and 74, use the Internet all the time. The research notes that almost 100% of respondents use the Internet at home and 40% use it at work. It should be added that there is an important social aspect—the mobile Internet opens up the world for people with disabilities, allowing them to live a full life. Indeed, according to data from the Ministry of Labor and Social Protection, almost 11.95 million people in our country have disabilities, but 95% of Russian mobile applications cannot yet be used by people with disabilities.

In this regard, the developers of the most popular Internet resources are actively transforming Internet applications: Google, Yandex, which, for example, creates resources for hard of hearing or deaf people, or, for example, for people with impaired sensory interaction (Federal Project "Digital culture" 2019).

Thanks to the widespread use of the Internet, digitization processes allow us to develop new channels for finding new jobs during employment, and job sites and social networks today occupy the 1st place in the dissemination of information about vacant jobs and the promotion of the candidate. Informatization will also lead to the transformation of the labor market and employment, in the near future—in 2022, the

emergence of about a quarter of new jobs in the world economy will be driven by digital technologies.

The Smart City system highlights various areas of digitization, including the possibility of remote utility payments, the development of public access zones to Wi-Fi, electronic diaries of pupils, etc. Recently, the direction of telemedicine, which becomes an intermediate modification between a doctor's visit to a clinic and so-called self-medication, has also been developed.

In addition to vital processes, the Smart City system is constantly added processes that make a person's life more comfortable and convenient, reducing the time spent on using various services.

Various services can be pointed out among them that can be obtained, issued and paid for online: rental of urban transport—from scooters to cars in the system of urban car sharing, remote educational programs, electric stations, making a variety of documentation, buying tickets and more. If individual services, such as car sharing or gas stations and some others, are not relevant, for example, for rural areas, almost all services are in heavy demand in large Russian cities. It is no coincidence that the digitization of the population, along with ensuring the safety of citizens, improving the environmental situation and many others, was included in the list of the 36 indicators of urban quality assessment, expressed through the definition of the quality index urban environment, which was approved in 2019.

In the practice of many educational institutions, projects are emerging to enhance the digital culture of learners, which imply the development of their competence in the use of modern information technology in the workplace and in the workplace Home.

At the federal level, the concept of digital culture is generally considered in the context of creating conditions for increasing accessibility and the possibility of Participation of Russian Citizens in the cultural life of the country [11].

Thus, the Federal Digital Culture Project has been in operation in Russia since January 1, 2019 with an end date at the end of 2024. The project aims to make culture accessible not only in major cities, but also in towns far from megacities. This is the goal of increasing the number of "references to digital cultural resources by 10 times by creating 500 virtual concert halls and 550 exhibition projects equipped with digital guides in augmented reality format" by 2024 (Federal Project "Digital culture" 2019).

In the age of the emergence of digital society, the development of cultural memory institutions that generate an electronic type of culture as a result of the transition to a digital civilization, which means the availability of the necessary infrastructure, is of particular importance. It provides access of the entire population to the resources of digital culture and introduces a new system of education that ensures that students have the competence to use and assimilate scientific information and knowledge using this infrastructure [4].

4 Conclusion

Thus, summing up the study of the social issues of the readiness of our society for digitization processes, we can note that the increasing lysing and digitization of the professional and personal sphere of each member society determines the increased responsibility of society itself for its protection, strengthening the efficiency of social mechanisms. Digitization has an impact on most well-established signs of the quality of life of the population. Government assistance in accessing educational and information resources contributes to the development of users' knowledge and skills, thereby giving them greater access to available opportunities for digital services and resources. Further digitization of the economy makes it necessary to promote a more effective cooperation between the state and administrative bodies, state structures, expands the limits of people's opportunities. Efforts should be made to develop digital competencies in the daily lives of people of all generations, regardless of their social status and place of residence, to take measures to eliminate digital illiteracy and to promote digital culture.

These are just a few factors that determine the need to strengthen the social aspects of digitization through the development of human skills to use digital information, its production and transmission through appropriate channels, through increased levels of digital information, digital literacy and digital culture of an individual and society as a whole. By creating the conditions for the use of digital services, goods or information, the state has a synergistic effect, as it provides solutions to the main tasks of improving interaction and involvement of residents in social processes, receiving feedback and the same opportunities, even if they are geographically remote or socially isolated.

Cognitive Security in the Digital Age: Types, Levels, Functions

Mikhail Yu. Zakharov, Irina E. Starovoitova, and Anastasia V. Shishkova

Abstract The article is devoted to the study of problems caused by the complication of digital civilization and related to the protection of knowledge and information from a variety of technological and sociocultural threats and risks. These problems can be solved by creating a single and integrated supranational system of knowledge security, the purpose of which is to ensure the cognitive security of society and the individual. The concept of «cognitive safety» is considered in philosophical and psychological senses in the article. The study used such classical theoretical philosophical methods as the method of generalization, analogy, abstraction, analysis and synthesis, the philosophical method of ascent from the abstract to the concrete. The logical and epistemological analysis is used to enter the necessary concepts. Results: 1. A distinction between the philosophical and psychological understanding of the phenomenon of cognitive safety is proposed. In a philosophical sense, cognitive security is the protection of the cognitive resources of society, which forms the social mechanism of control over the storage and using of the intellectual property of society and other spiritual values. There is lack of realization of potential threats to the homeostatic functioning of cognitive and mental processes psychologically. 2. Three levels of cognitive security are distinguished: global cognitive security (security of society as a whole), information and cognitive security of social groups and social communities, information and cognitive security of individuals. 3. Two main areas of information and cognitive security of the society—information security and knowledge security—and their universal functions: protection, social memory and adaptation, have been identified. The protective function ensures the observance of the natural human right to information and protection against it within the legal framework. The function of social memory is storing certain socially significant

1 Introduction

Modern society is called the knowledge society. Indeed, knowledge and objectified knowledge–information–become the main factor of production, a strategic resource and the highest value. And this value needs protection from a variety of technological and sociocultural threats and risks. The prospects for the using of digital technologies due to their applied nature aren't sufficiently studied by philosophers and cultural scientists, and the complexity of digital civilization leads to the fact that optimistic long-term forecasts of digitalization don't look reliable.

On the one hand, society must guarantee the preservation of public knowledge and also the form a cognitive culture and ensure public access to cognitive resources. A unified, supranational system of knowledge security systematically creates the conditions for ensuring all stages of its life cycle, which include: occurrence, translation into an information form, transfer, storage and destruction.

On the other hand, the cognitive security of the individual is at risk. The constant online presence in the modern digital world, the Internet of things, «big data» , artificial intelligence technologies have penetrated into all spheres of our life and they are already helping the state and individual corporations to better monitor all kinds of aspects of people's lives, violating their personal space. Digitalization, together with the spread of mass culture through the media, gives rise to many problems that need to be understood and resolved as soon as it's possible.

2 Methodology

The authors used such classical theoretical philosophical methods as the method of generalization, analogy, abstraction, analysis and synthesis, the philosophical method of ascending from the abstract to the concrete during the study. The authors also used logical and epistemological analysis to enter the concepts necessary for the study.

The concept of «cognitive safety» is considered philosophically and psychologically.

Cognitive safety (in a psychological sense) means «the lack of realization of potential threats to the homeostatic functioning of cognitive (thinking, memory, language) and mental processes» [1]. Cognitive safety is determined, firstly, by a special stable device of the human body, secondly, by psychological self-identification of a person, and thirdly, by the harmonious nature of social dynamics.

Cognitive security (in a philosophical sense) is the protection of the cognitive resources of society, which forms the social mechanism of control over the storage and use of the intellectual property of society and other intangible values. Cognitive security is associated with human rights such as the right to free access to information and freedom of speech. Providing conditions for the free movement of knowledge, this type of information security protects society from attempts to violate its information boundaries through psychological suggestion, religious or ideological manipulation.

It's legitimate to speak of three levels of information and cognitive security: information and cognitive security of the social macro-system, society as a whole, that is, global cognitive security; on the information and cognitive security of social groups and social communities; about information and cognitive security of specific social organisms, that is, individuals.

3 Results

3.1 Psychological and Cognitive Safety of Man and Society

In the modern world, the configuration of social space is globalizing, information flows are multiplying and becoming excessive in their quantitative and qualitative characteristics. Human cognitive abilities are powerless in front of them.

The widespread use of digital technology leads to the alienation of information and knowledge from man and mankind. The famous English sociologist E. Giddens discusses the distance of a person from information and knowledge [2]. It can be stated that in the context of the spread of digital and virtual reality technologies, the limitations of the individual presence of the subject have been overcome, that the communicative, cognitive and even objective-practical forms of activity become unlimited in time and space, moving away from the subject of activity.

Large social organisms (social communities) and the individual are experiencing, crisis phenomena of a psychological nature is a result of all this. Due to the massive nature of political and media manipulations, diverse cognitive threats to public consciousness arise. Radical changes in the socio-economic sphere have led to a real technological explosion of the cultural and mental space [3].

First of all, we have to admit that the ability to think logically becomes much less common in modern young people than in the previous generation. The clip-based way of presenting information gradually led to the emergence of the phenomenon of «clip thinking» (inability to focus for a long time on a cognizable object) [4, 5].

This is due to the fact that specifically human thought processes become significantly less popular, such reduced thinking is quite enough to perform stereotypical actions that are characteristic of many professions of post-industrial society, for functional non-creative work.

Secondly, there is a disproportion of the purposeful and value-rational actions of man. As known, M. Weber refers to the actions or behavioral acts performed by people purposefully, consciously, with a clear intention to achieve specific results under the purposeful behavior [6]. According to the concept of M. Weber, rationality awareness of actions is the higher as the higher social status an individual occupies, and vice versa, the lower a person in his status, the more he is guided by irrational motives in his actions. On the contrary, value-rational actions are guided by unconditional values (aesthetic, religious, ideological and other cconvictions).

In the socio-political sphere in the era of digitalization, the cognitive sphere of social communities and individuals is continuously influenced by political technologies and the media. Political strategists and media appeal to the mythological, illogical and irrational. A person doesn't form an adequate image of social reality, since the media have become an important tool for the socialization and social adaptation of modern man. Myths and quasi-myths become regulators of people's social behavior.

The cognitive and sensory spheres of man are developing asymmetrically under the influence of digital media. The emphasis on bodily consumption inevitably jeopardizes a person's cognitive status. A relatively recent threat to the cognitive security of an individual can be seen in Internet phenomena such as hacking, flame, trolling, bullying, etc.

In the opinion of the authors of the article, the cognitive security of the individual can be ensured by stabilizing the structure of social space, while relying on a system of indirect sociocultural factors, the most important of which are values for the individual. We can agree with the statements of modern Russian researchers: «No social system, no single state can function and develop without a value system that unites its members» [7].

«It seems important that there exists and manifests itself in various formats as a systemic relationship between the psychological safety of an individual and the mental state of society» [8]. «An important safety factors are: the understanding, respect, consideration of authentic and mutual value systems of various subjects of safe development» [7].

3.2 Levels and Functions of Information and Cognitive Security

There are two areas can be distinguished: information security (which appears in various forms) and knowledge security in the structure of information and cognitive security of modern society.

The adequacy, integrity and consistency of the picture of the world have a big importance at all stages of socialization and resocialization of a person, and they also represent the ideological basis of personal growth. Such a picture of the world is built under the condition of guaranteed information and cognitive security.

The information and cognitive security system is divided into two main functional subsystems that are in unity.

The first subsystem (root) is the main component of the overall security system that makes up a single integrity with society. It includes laws, norms, standards, standards and rules for organizing the safe life of society, which were formed during the historical development of society. In practice, this subsystem appears in the form of the aggregate policies of states and other political institutions, historical traditions of safe life, national customs and rules of safe behavior in everyday life. The totality of all these norms determines the content and orientation of public consciousness, forms the paradigm of public safety [9].

We will name the universal functions of the root subsystem of information and cognitive security: social memory, protection, adaptation.

The main task of the fundamental subsystem of information and cognitive security is the preservation and subsequent transmission of the information image of the system of safe existence and development of society.

Here we are talking about the function of social memory, which consists in the rational storage of socially significant information and organized in such a way that it's convenient to use. It's logical to distinguish two levels of social memory: individual memory, which is formed as a result of personal information activity of people, accumulating their personal experience of safe existence (the most important of the social institutions that form individual memory is the educational institution); public memory, accumulating information significant for the safety of society. The latter ensures the survival and progressive development of all subsystems of society in conditions of social dynamics. The fundamental subsystem of information and cognitive security accumulates information and knowledge not only about the current state of the information sphere of society, but also about the main stages of its formation, the dangers and contradictions that arose with it and also about the experience of overcoming dangers and resolving contradictions.

The translation mechanism provides a communicative transfer of information and knowledge from generation to generation, thereby guaranteeing the integrity of this sphere of society. For preserving the qualitative specifics of the information sphere, the ability of the indigenous subsystem to quickly and sufficiently absorb information and knowledge from the internal and external environment and equally quickly and correctly respond to them plays a decisive role.

In the past, in the era of the stable existence of such closed political entities as the national states, the concept of social memory characterized the continuity and reproduction of a stable stock of historical knowledge that determines national identity [10].

But in the global world there is a violation of integrity and consistency, the erosion of social memory, due to the erasure of state and ethnic boundaries. The structure of the social space has changed, as a result of which «the memory of a single world

community, the memory of global social institutions that take on the function of representing the world community in certain areas of human activity (UN, NATO, etc.) gradually replace national memory» [10].

Every innovation in the socio-economic sphere, due to its complexity and versatility, is fraught with risks. The authors of the article consider the digitalization of all knowledge to be such a riskogenic factor. In the digital era, the technical means of storing and transmitting social memory are fundamentally changing. In the post-industrial period, society was faced with the fact that the volumes of digital information significantly exceeded the totality of information on other media [11].

At the same time, no one can guarantee knowledge in electronic form of a long life: there are more and more new ways to save information and the life of digital documents is steadily decreasing. In addition, computer technology is constantly updated, new software is being developed. The enormous volumes of information and the imperfections of the devices, which transmit and process information, along with man-made and man-made risks, jeopardize the integrity of global social memory and lead to the loss and falsification of large amounts of data.

Some influential social subjects «seek to precede their own local history in «the global world memory» , using the resources of computer technology and the media» [10]. Thus, the value component of public life is threatened, and identification risks appear. The socio-economic convergence of states and peoples in the context of globalization didn't lead to the elimination of conflict and it didn't minimize the risks.

On the contrary, the flip side of globalization is ethnosocial divergence. And the destruction of social memory contributes to this destructive process of ethnic disunity. In conditions of high riskogenicity, society begins to strive for stability and security.

The second functional subsystem of information and cognitive security is specially formed to preserve and organize the normal existence of the root subsystem. It performs a protective function, the purpose of which is to create a safe environment for the activities of international social institutions and to respect the natural human right to information and protection from it in the framework established by laws.

The protection function also provides tracking, absorption of potentially dangerous information-cognitive impulses and the issuance of directive information to relevant organizations. For the practical implementation of this function, it's necessary to be able to withstand real and potential threats, primarily related to information theft, with unauthorized entry of personal or secret data to the Network.

The using of artificial intelligence algorithms is coupled with a number of ethical difficulties associated with privacy and at the same time transparency of data, the right to keep personal information confidential, and the asymmetric distribution of information between different agents. The aspect of digital discrimination is still poorly understood. Who owns the information that owns the world: the collection, analysis and use of «big data» can lead to increased social power and control on the part of those who have the necessary algorithms in their hands.

Researchers note that we must recognize now that individuals and social groups are in far from equal conditions when interacting with digital data [12].

An important function of the protection (support) subsystem is also the adaptation of the indigenous subsystem and society as a whole to the surrounding socio-technological environment. The adaptation function is a special form of control and regulation. Monitoring consists in constant verification and monitoring of the conformity of the activities of the indigenous subsystem with generally accepted standards, norms and safety rules.

In real life, the adaptive function is appeared in using legislative acts to stop the adoption of erroneous decisions that undermine the information and cognitive security of society. Another specific form of the adaptation function is regulation, which consists in the targeted regulation of the information flow, ensuring its efficient and rational flow. The adaptation function contributes to the stability of a modern risk society.

The basic subsystem of information and cognitive security of a society, with all its relative stability, will inevitably transform under the influence of changes in the surrounding information reality.

4 Results

A society can be considered a safe social system only if any individual, social group or social institution can legally obtain information and knowledge necessary for a reasonable life support at any point in space.

Society in the digital age is called upon to guarantee the safe use of information and cognitive potential for a comfortable existence of people and the progressive development of society. A rationally organized system of unified information and cognitive security is able in practice to provide comfortable information conditions and protect the information rights of social entities.

To form such a system, it seems necessary for us to further develop the concept of «cognitive security» , within the framework of which it's proposed to use the structural-functional organization of cognitive security described in this article: (1) the distinction between the two types of cognitive security–psychological cognitive and information-cognitive; (2) the allocation of three levels —global cognitive security (security of society as a whole), information and cognitive security of social groups and social communities, information and cognitive security of individuals; (3) recognition of the basic functions of the cognitive security system of society: the protection of knowledge and information, social memory, adaptation to the surrounding socio-technological environment.

France's Role and Place in the Digital Economy

Lyudmila D. Efanova

Abstract This article deals with the main features of digitalization of French economy in the conditions of globalization and development of Internet trade and advanced technologies. The key characteristics of the modern stage of French digitalization development are revealed. Economic activities based on advanced digital technologies and related to e-commerce and e-business are actively formed and spread in all economically developed countries of the world, including France. Within the framework of the article the author analyzes the French digital economy, considers the stages of its development in the modern conditions using examples of specific economic spheres. The results: 1. Different approaches to setting the meaning of the concept of digital economy are outlined and its key characteristics are identified. 2. The peculiarities of the current state of the key French sectors of economy affected by digitalization are determined. 3. Various assessments of the level of digitalization of the French economy are considered and particular measures to overcome the existing gap are proposed. 4. The national strategy for the development of artificial intelligence is considered and key measures to achieve the goals set by the country's authorities, namely, the achievement of France's leading position in the development and application of artificial intelligence, are identified.

literacy and awareness. At the same time, electronic means of communication are in the process of continuous improvement, more than half of the country's population exchanges information through social networks and messengers.

It should be noted that lately more and more scientific and business spheres have become closely connected with computer sciences. Such terms as neural networks, machine learning, deep learning and data sciences are used everywhere. Therefore, the rapid spread of methods of information exchange via the Internet, various electronic networks and communication channels inevitably leads to the development of the digital economy.

The main competitive advantage of digitalization is to optimize the production of goods and services, as well as to increase productivity. Many companies, as well as countries, are actively introducing digital technologies, in order to achieve the obvious benefits that the new wave of the technological cycle brings [1].

2 Methodology

The following scientific research methods were used as a methodological basis:

- analysis: "almost all French enterprises (about 99%) use a high-speed Internet connection. At the same time, the exchange of information for supply chain management and electronic invoice management is still low. There is also potential for wider adoption of cloud computing, big data analysis and radio frequency identification (RFID)—less than 17% of enterprises have used this technology";
- classic approach: "the digital economy is often described as a set of different economic activities within the information and communication technology sector";
- comparative method: "France is ahead of Great Britain and Germany in terms of the level of digitalization of interaction between the population and the state and is inferior only to Sweden";
- analytical method: "the available information on the current state of the French digital economy shows that the country's government has generally succeeded in achieving its goals through digitalization".

3 Results

France is one of the leaders in digitalization in the economic and business spheres for 2019. France is the third largest ICT sector in Europe. ICT now accounts for about 5% of France's GDP (about 80 billion euros), which exceeds the share of agriculture and energy in GDP. At the same time, most of the added value comes from ICT services. Information and communication technologies are the most important sector of the economy, they are one of the innovative drivers of the digital economy [2].

France is one of the key European countries contributing to the world digital economy. It has the following advantages: a strong user base, substantial infrastructure, high-quality mathematics and science education.

The digital economy accounts for 3.7% of jobs in France, 5.2% of GDP and 7.9% of total private sector value added, and more than a quarter of private sector research and development (R&D) activities. The share of the digital economy in the GDP of developed countries is increasing annually [3]. Over the past 15 years, the Internet has created 700,000 workplaces, or 2.4 jobs for each job abolished. Moreover, the digitalization of work and workplaces creates completely new categories of professions and, consequently, people with new digital thinking [4].

In 2019, the French Minister of Economy and Finance Bruno Le Maire in an interview with "Le Journal du Dimanche" said that the French government was in the final stage of drafting a law related to the taxation of corporations in the digital sector. The tax will impact companies operating in the field of digital services, which have an annual working capital of over 750 million euros worldwide, as well as more than 25 million euros within France [5]. The issue of tax regulation of international digital corporations such as Amazon, Google, Facebook, Apple was defined by the minister as "the great challenge of the twenty-first century". This statement is particularly remarkable against the backdrop of policies to enhance the country's digital capacity [6].

An assessment of the current state of development of the digital economy in France requires a definition of the digital economy. Approaches to assessing this issue are based on either a "narrow" (sectoral) or "broad" (universal) understanding of the phenomenon.

The Centre for Digitalization (Observatoire du numérique), which operates under the General Directorate for Business of the French Ministry of Economy and Finance, states that, for the purposes of public statistics, the digital economy is often described as a set of different economic activities within the information and communication technology sector. According to the approaches of the Organization for Economic Cooperation and Development and the French National Institute for Statistics and Economic Research, the information and communication technology sector brings together businesses that produce goods and services related to the transformation of information into digital data [7]. The ICT sector is one of the key sectors supporting the development of the digital economy.

Experts from the French Digitalization Centre suggest distinguishing between four groups of participants in the digital economy: the ICT sector, new digital industries (online services, e-commerce, etc.); enterprises that use ICT intensively in their main activities to increase productivity (banks, insurance companies, car industry, public administration, tourism, etc.); citizens who use information technology for personal purposes [8].

Thus, we can conclude that today in developed countries digital technologies have stepped far beyond the information and communication technology sector and penetrate into all existing industries, forming a completely new type of economic model [9]. The government of France has repeatedly stated its desire to take one of the places among the leaders of digitalization.

Nowadays almost all French enterprises (about 99%) use high-speed Internet connection. At the same time, the exchange of information for supply chain management purposes, as well as for electronic invoices, is still low. There is also the potential for wider adoption of cloud computing, big data analysis and radio frequency identification (RFID)—less than 17% of enterprises have used appropriate technologies. More than half of French companies use the Internet and Electronic Data Interchange (EDI) for online procurement. Today, innovative payment methods allow for instant payment and profit without delays [10]. According to this indicator, France is much higher than the average European level [11].

The digital development of interaction of juridical and physical persons with the state continues. Approximately 90% of juridical persons make transfers of social insurance contributions online. Approximately two thirds of all companies pay fines and customs duties electronically. About 50% of the French population submits tax returns online and about 60% pay taxes using electronic systems. France is ahead of Great Britain and Germany in terms of digitalization of interaction between the population and the state and is inferior only to Sweden. According to the Open Data Index 2016, France ranks Fourth among all countries in terms of availability of government data.

More than half of the French population uses electronic banking services. Two thirds of the population purchases online at least once a year. The volume of e-commerce has increased more than 4 times in the last 10 years (over 70 billion euros). At the same time, about 10 billion euros is accounted for trading via mobile devices—this segment has grown 11 times over the last 5 years [12].

It is worth paying attention to the fact that the total share of investments in information and communication technology development is about 20% of all investments in research and development carried out by French companies.

In France, five innovation clusters support the digital economy:

- Cap Digital (Île-de-France) for digital content creation and multimedia distribution and sharing;
- Images et reseaux (Bretagne and Pays-de-la-Loire region) for networks;
- Minalogic (Rhône-Alpes region) for smart miniature products and solutions for industry;
- Secure communication solution (Provence), for secure processing and communication solutions;
- Systematic (Île-de-France), for complex systems and general software.

Speaking of key sectors, French telecommunications networks are among the best in the world today. Investments in cloud computing, a 25% annual growth in e-commerce and five specialized innovation clusters (Cap Digital, Images and Networks, Minalogic, SCS and Systematic) support development in this area.

According to the Information and Communication Technology Development Index of the International Telecommunication Union, France ranked 15th in the world in 2017, which enabled it to move up two positions compared to the previous year and bypass the USA among others [2].

At the same time, according to a study conducted by Tufts University (USA) in collaboration with Mastercard Digital Evolution Index, France was ranked among the group of countries with slowing growth rates of digital economy. In order to overcome the "digital plateau", experts recommend that such countries make a conscious effort to rethink their economic model, "bet all" on the digital technologies and technological areas in which they lead, and remove any obstacles to innovation.

France's progress is also measured modestly by the Digital Economy and Society Index (DESI), a composite index of digitalization in the European Union. As in the previous year, in 2018, France was ranked 18th out of 28 EU member states. The country made progress in the acquisition of digital skills by citizens. At the same time, the level of access to networks was estimated by the DESI compilers to be below the EU average, in particular due to insufficient coverage of the territory by 4G mobile networks. In terms of the use of digital technologies in the commercial sector, France did not reach the European average. The level of e-government development was described as average. However, the authors of the Index state that the French "Great Investment Plan 2018–2022" provides for the allocation of 9.3 billion euros over five years for the digital transformation of the state.

France today is one of the leading countries in the field of high-speed Internet: it is the second largest in the EU by this indicator. E-commerce in France accounts for 25% of annual growth, revenues of more than 40 billion euros (as well as distance selling), about 70,000 workplaces (full-time equivalents), more than 30 million online buyers and 10% of the revenues of specialized companies.

France is home to many famous online trading platforms. The Frenchman Pierre Kosciusko-Morizet has created the popular online sales platform PriceMinister. It is the fifth most visited electronic sales website in France (after Amazon, Cdiscount, eBay, Fnac). The online designer brand store vente-privee.com, founded by Jacques-Antoine Granjon, has also become a world hit.

France has created some of the most successful non-American startups such as Deezer (predecessor of Spotify), Dailymotion (created before YouTube), Criteo and Ventesprivées.com. It is often the French companies that are the finalists in the international startup competition.

The French market includes 100 data centers, about 40 of which are located in the Paris region. Data centers of major French operators, such as Orange France Telecom and Atos, are developing in France and abroad.

Multinational corporations such as IBM, Interoute, Interxion, Telecity and Telehouse are investing about 1 billion euros per year in the French market. They are attracted by France's renowned engineers and technicians, its secure and affordable electricity supply, as well as national legislation ("Computers and Freedoms Act" and data encryption legislation, "Digital Economy Confidence Act"), which provides optimal legal security requirements for data protection and processing.

The French video game industry is the second largest European market.

France is home to world-renowned companies Vivendi (the world's largest publisher), Ubisoft (the third largest publisher in the world and the largest in Europe) and Big Ben Interactive (the largest distributor of video game accessories in Europe).

This sector employs over 5000 people. France is the second largest provider of video games for Facebook in the world.

France today attracts many foreign digital companies. Foreign companies established in the French market include Ad Ultima, Yahoo, Brightcove UK Ltd., Celum France, Intel, Glam Media, Neovini, Jovent, Microsoft, Peppercan, Google, Teamquest Corp., Wave Software, TurboHercules, 360 Innovation, Experian CheetahMail. and eCairn France. Intel has opened a dedicated wireless technology center in Nice. The Smart Technologies group, one of the largest experts in collaborative solutions, has chosen the Paris region for its European office.

French companies are digitizing: 86% pay VAT online; 24% of companies with over 10 employees use an information management system; 13% sell online; 27% buy online.

The French government strives to create the prerequisites for a structural transformation of the country's economy through the widespread digitalization and widespread introduction of artificial intelligence technology. In 2018, French President Emmanuelle Macron announced his intention to allocate more than 1 billion euros for research and development in the field of artificial intelligence in the next 5 years.

The national strategy for the development of artificial intelligence presented by Macron is mainly based on the report "Giving meaning to artificial intelligence: towards a national and European strategy", which was prepared by the French National Assembly deputy, mathematician Cédric Villani.

The following measures are proposed in the present report:

1. Development and implementation of an "offensive" data policy. The state should encourage data exchange between companies. Facilitation of access to data of public interest is required. The right to "portability" of data (the ability to transfer data from one service or ecosystem to another without loss) should be enforced.
2. Focusing policy and work on four sectors—health, transport, safety and environment. In this area it is also proposed to develop platforms for coordination and exchange of profile information, as well as to create "regulatory sandboxes" – special modes for testing new technologies.
3. Strengthening of French research and development capacities. Interdisciplinary research institutes in the field of artificial intelligence will be established at universities and research centers throughout France. The need for appropriate research resources, including a supercomputer designed specifically for artificial intelligence, has been identified. The importance of providing material support to French researchers, encouraging the return of domestic specialists who have gone abroad and attracting foreign experts was stressed.
4. Regulation of artificial intelligence impact on labour relations. It is proposed to create a commission/committee on the issues of evaluation of the activity in the digital field. It is also assumed that this organization will deal with the transformation of labour by means of artificial intelligence. Emphasis is placed on the need to develop complementarity between people and machines. The importance of updating the funding mechanisms for training programs was noted.

5. Artificial intelligence and environmental safety. The Government of France is encouraged to use artificial intelligence technology for "environmental transformation" (transition to a more environmentally friendly economic model), i.e. finding ways to make artificial intelligence less energy-intensive. Moreover, it can also be involved in solving practical tasks related to wildlife conservation.
6. Ensuring that new technologies comply with moral and ethical standards. The authors propose to ensure the transparency of digital algorithms, also propose to raise questions about the ethical responsibility of developers and to establish an advisory committee on the ethics of digital technology.
7. With regard to the issue of equality and diversity in the digital sphere, the authors propose to increase the proportion of women studying in applied computer science programs to 40 percent. Emphasis is placed on the need to support programs for social innovation based on technology.

One of the first practical steps to implement these plans is the French government's authorization to test autonomous vehicles from 2019. This step seems to be quite timely, as today a real race for the championship in the use of artificial intelligence in transport is unfolding.

The "Digital Boom" affects a wide range of industries, among which the financial sector plays a special role. At the meetings of G20 ministers and central banks' governors in Buenos Aires, Minister of Economy Bruno Le Maire noted the desire of France to become a leader in the regulation of cryptographic currency [13].

The implementation of this objective was marked by the creation of a dedicated working group. The sphere of its activity included development of rules for regulation of digital currency, as well as appropriate measures to counteract use of cryptocurrencies for committing financial crimes, tax evasion, money laundering and terrorism financing. Jean-Pierre Landau, an experienced financier and former deputy governor of the Central Bank of the country, has been appointed head of the working group.

The French leadership has set specific goals for the digital transformation of the country in the coming years. To achieve them, it is important to encourage French technology startups to become world leaders. The importance of helping companies in the "traditional" economy, especially small and medium-sized enterprises, to achieve their digital transformation, is also emphasized.

Meaningful steps should be taken towards creating a "state platform" and developing microservices that would function on its basis.

By 2022, it is planned to transfer the state to a fully electronic document management system.

Reinforcing the statements with certain steps, on 28 November 2018 in Toulouse, M. Mahjubi and the Minister of Higher Education, Research and Innovation F. Widal presented the main directions of the national research strategy in the field of artificial intelligence. The government plans to spend 665 million euros for this purpose by 2022. The French government estimates that, taking into account private sector investments, the total budget of measures may reach 1 billion euros.

It is expected that interdisciplinary centers in the field of artificial intelligence will be established, where both public and private specialized research will be conducted.

The possibility of deploying such centers at four universities – in Paris, Toulouse, Grenoble and Nice—is being considered. Public funding for this initiative is estimated at 300 million euros. It is planned to attract another 100 million euros from private investors.

In addition, the French government is going to open 40 new departments to teach computer science in national universities. The National Institute for Research in Computer Science and automation (INRIA) will be responsible for coordinating this program. Also in the period up to 2022, it is planned to provide material support for studies of 300 young scientists in the field of information technologies. It is planned to allocate 130 million euros for this purpose to technological research institutes.

It is planned to finance researchers' access to computing resources by 2022 in the amount of 200 million euros. In particular, a new supercomputer is scheduled to be launched at the laboratory site of the Institute for Development and Scientific Computing Resources in Saclay in 2019. 115 million euros will be allocated to promoting international cooperation in the field of artificial intelligence.

The French national investment program includes:

- 2 billion euros for the Internet infrastructure (very high mobile bandwidth, fiber optics and digital satellite transmission) to cover the entire country by 2025;
- 2.25 billion euros to support innovative digital services, content and applications;
- 250 million euros for smart grid development.

In the plan for the digitalization of France, 57 new priorities for the development of the digital economy were set for 2012–2020, including:

- increasing digital coverage to 100% of companies in France, including very small companies;
- ensuring high definition of all digital terrestrial channels, developing interactivity and mobility and launching at least one 3D channel;
- paperless administrative formalities by 2020.

Available information on the current state of the French digital economy shows that the country's leadership has generally succeeded in achieving its goals through digitalization.

At the same time, the discrepancy between France's own assessment of its progress towards digitalization and that of its "external" assessment indicates some difficulties in the country's digital development.

4 Conclusion

It is obvious that in order to achieve the indicators and goals set by the leadership of France, namely, to achieve the leading positions of the country in the development and application of artificial intelligence and in the regulation of cryptocurrency, as well as the entry of national technological start-ups into the ranks of international

leaders, it becomes necessary to rethink the existing economic model, focusing on the most promising areas in which France has a fairly serious technological base.

The national strategy and plan of work in the field of artificial intelligence, which determines a new stage of digitalization of the French economy, is aimed at solving these problems. It should be noted that in France, as well as in other countries that are on the way to digitalization and digital transformation, it is necessary to increase investment in human resources, that is, investment in education and acquisition of skills necessary to work on the process of digitalization, because the leaders in the digitalization of the economy will be those countries whose population will be sufficiently skilled and ready for this transition.

Formal Characterization of the Impact of the Institutional Environment in the Digital Twin of the Enterprise

Mikhail V. Samosudov

Abstract The purpose of the article is to give a formal characterization of the institutional environment of the social system and its impact on the behavior of participants and the system for digitalization and automation of management, including the design of a digital twin of the enterprise and simulation of a social system model. The problem is solved by the method of mathematical simulation, which became possible due to the resource-functional approach to the analysis of social systems, the development of the behavior vector concept, and techniques of the quantitative assessment of all types of resources involved in activity, formalization, and recording of human conduct. To solve the problem, we should clarify the nature of corporate systems, which are a special case of social systems, to establish a relationship between the functional events and the resource base, as well as between the company's resource base and the acts of the parties to relations. The development of the behavior vector concept allowed introducing into the mathematical models of the social system the specific acts of interacting parties, information flows and messages, and solving the problems of performance optimization. With that, social institutions are considered in a specific sense as an information object (rules, regulations, etc.) affecting the behavior of the system participants. Using the developed approaches, we identified the parameters of social institutions, firstly, variables distinguishing one institution from another (specifying it), and secondly, ones enabling assessment of institutions' impact on the behavior of participants in the social system. The newness lies in that the institutional environment and particular institutions are formalized in a matrix, which is suitable for mathematical models and computational algorithms. This allows us to record in the digital twin of the social system formal and informal institutions, including regulations, corporate culture, stereotypes, and other phenomena influencing the system state. In the calculation of the controlling actions, this enables, firstly, to estimate the managerial effect with respect to the impact of the institutional environment; secondly, to predict the required changes in the institutional environment to attain a controlling action.

1 Introduction

Nowadays, enterprises under the Industry 4.0 concept are often built on the principle of cyber-physical systems, and the concept is premised on the incorporation of its virtual image in the production system as mathematical models or, in other words, a digital twin [1, 7, 8]. The term "digital twin" appeared more than 15 years ago in the works by Grives [6], and the concept is getting more developed due to growing interest in automation. But even in terms of high automation, man-decision maker remains a significant element of cyber-physical systems [13].

Automation of the enterprise activity requires formalization of processes at the level of phase variables, and the models under use should provide an ability to trace the impact of all key variables on the state of the enterprise. If the ability is not provided, then adequate algorithms for future programs cannot be formed.

The latest technological solutions allow can partially automate the activity. And one of the essential parts, management, defy automation by modern techniques. In particular, due to the insufficient rigor of the theories for describing this activity, conversations about motivation, leadership, charisma, etc. are not translated into digital language, and the computer does not accept another. Therefore, the programs used for automation of control are able only to gather some (but not always relevant) data about the processes. This partially facilitates the manager's work but does not solve the problem of automation.

2 Problem Setting

A digital twin is a computer model that simulates the behavior of a real object, i.e. a simulation model [2, 14–16]. It can be used in the control system as an "active advice-giver", which allows comparing the effect of the decision by control entity and the solution offered by the computer [3–5].

Notably that, for individual parts, assemblies, equipment, and processes, many simulation models forming a part of digital twins are very detailed and lowly-abstracted [14]. But this is not true for attempts to form digital twins in social systems.

In the works by Samosudov [9, 10] the main components of a complex mathematical model of a social system operating in an active environment are recounted. Application of a resource-functional approach to the analysis of social systems;

clarification of nature, formalization and engagement of human activity and social systems into the model helped to form dependencies linking the phase variables of the social system and environment of its operation with the results of the activity, the incoming resource flow comprising the incoming cash flow. The development of techniques to describe and record the values of the phase variables of a social system allows talking about a computer program that can be designed to record the state of the social system and its alteration in the course of activity, that is a digital twin of the enterprise. And the formalization of dependencies linking phase variables with functional events makes it possible to design a program to estimate the effect of changes in the values of some parameters[1] on the properties of a social system (simulation model). This allows for the calculation of the functional (systemic) stability of the company, the level of activity risk, prediction, and adjustment of the development path as well as deviations of the actual path from the estimated one.

Alongside, the implementation of computational algorithms for a digital twin of an enterprise requires formalized action of all influencers, including the institutional environment in general and some social institutions in particular. This is one of the essential influencers of human behavior and, as a consequence, the distribution of resources in the socio-economic space (SES). Regard to the impact of the institutional environment enables a more accurate prediction of the system response to the controlling actions of active participants.

3 Problem-Solving Technique

In this paper, we employed the method of mathematical simulation and a complex mathematical model of a social system operating in an active environment [10].

Firstly, we clarified the nature of the social system. In particular, we showed the resource basis of the relations of parties to the social system. The person at his own free will transfer resources by means of certain acts [9]. Resources are regarded in a broad sense, and the developed approaches help to quantify all types of resources (information, social, material, intellectual, spatial, organizational, etc.).

After identifying the role of resources for the company's performance and the establishment of a linkage between the resource base and the acts of participants, we set the task to make the recording the acts of parties to relations within the model possible. The concept of a behavior vector greatly contributed by neurophysiological works of the Ukhtomskiy-Simonov school (see, for example, [11, 12] is taken as the basis. But we also took heed of papers in the field of social studies, psychology, human ethology, biological cybernetics, etc. (for more details, see [9].

Behavior is regarded as a feature of a person, showing the probability of a certain conditioned act. Moreover, any act o_n performed by persons in the social system is formally characterized by the dependence: $R_{init.} \xrightarrow{o_n} R_{res.}$, where $R_{init.}$ и $R_{res.}$ are

[1]The terms "phase variable" and "parameter" are here regarded as synonyms. A parameter (phase variable) is a variable linked by a known dependence with the state of a process or system.

initial and resulting sets of resources respectively [10]. Besides, activity as a set of acts can be characterized by a specific resource trace, a sequence of resource base transformations that ensures the desired result; and fixing this trace using a digital twin can accurately assess the status of activities. This can be used for automation of control.

To record the behavior in models, a behavior vector is used in the basis of conditioned acts O (the value that allows measuring behavior and recording it in models). This is a $1 \times n$ dimension matrix, where each element determines the probability of *n-th* act:

$$B(O) = \big(p(o_1) \ \dots \ p(o_n) \big), o_n \in O$$

On the back of the analysis of information about human behavior [9]; pp. 422–432), we identified the factors affecting the probability of an act. It is shown that the latter is equal to the act choice probability, based on the person's assessment of the importance of stimuli (attained resources) and limitations (resources lost in the act), approaches to the act probability estimation.

4 Formal Characterization of the Institutional Environment

Information $D_{incom.}(t)$ received by a person from various sources (in SES these are active participants sending messages via selected channels) is translated by the human consciousness into a set of signals $\{d_n\}$, which together set the change in his estimates of existing stimuli, limitations, and the probability of these effects associated with the execution of certain conditioned acts, which results in changing behavior [10]:

$$D_{incom.j}(t) \overset{B_j(O_j,t)}{\rightarrow} \{ d_1 \ \cdots \ d_n \} \overset{B_j(O_j,t)}{\rightarrow} \Delta B_j\big(O_j, t+1\big)$$

A study [9] showed that one of the information sources on stimuli and limitations is formal and informal social institutions.

Bearing in mind the existing definitions, we formulated a working definition of a social institution as *information about the acts and their consequences that will be received by the person observing the behavior of other participants or from documents* [9].

The consequences of the acts for the person are attained and lost resources, stimuli and limitations designated as s_n и l_m respectively.

From the perspective of the analysis of the social system and interactions, *institutions are means of translating the behavior vector* relevant to the institutional environment. Reflecting on the human mind, information from institutions is supplemented by details about required and available resources. As a result, the behavior

vector changes, as well as the basis of the behavior vector (a set of conditioned acts), the stimuli, and limitations associated with them. Along with that, the vectors of the participants' behavior affect the institutions, i.e. information about the right or wrong acts, their consequences, and probability for the person.

The parameters of the institutional environment (composition, the strength of the influence of particular institutions, the translated behavior vector) is one of phase variable groups in a social system, qualifying its state. These parameters allow predicting human behavior and, as a consequence, activity and its results.

Let's denote the *k-th* social institution by the symbol h_k and the set of institutions in the social system Ω as H_Ω.

Let's define *an elementary social institution is one determining the stimuli* s_n^k *and limitations* l_m^k*, as well as the probability of these consequences for the conditioned act* o_k.

The elementary institution is written by the following tuple:

$$h_k = \left\langle o_k s_1^k, \ldots, s_n^k p\left(s_1^k\right), \ldots p\left(s_n^k\right) l_1^k, \ldots, l_m^k p\left(l_1^k\right), \ldots p\left(l_m^k\right)\right\rangle$$

where:

h_k—the *k-th* elementary social institution;
o_k—the *k-th* conditioned act;
s_n^k—stimuli for the commission of the act o_k, that is, resources of *n-type* obtained during the act;
l_m^k—are limitations for the commission of the *k-th* act, resources of the *m-type* lost during the act;
$p\left(s_n^k\right)$, $p\left(l_m^k\right)$—is the probability of obtaining resources of the *n-type* and losing resources of *m-type* in the commission of act o_k respectively.

The institutional environment H_Ω of the social system Ω is a combination of elementary social institutions of this system: $H_\Omega = \bigcup_k h_k$. Similarly, the institutional environment H_Θ SES Θ of the system operation is a combination of elementary spatial institutions.

For analysis of the institutional environment of the social system, one can use the following table (Table 1).

The table is large since there are many types of acts, stimuli, and limitations in the social system. But often it's enough to carry out an analysis of the environment of one unit and only for certain conditioned acts. Besides, it seems possible to record the institutional environment in the digital twin of the enterprise, and use the required "slice" in calculating controlling actions. Altogether, this allows identifying the features of the institutional environment such as redundancy or insufficiency of institutions, contradictions or duplication, etc.

So, the institutional environment of the social system Ω is formally characterized by a matrix of dimension $k \times [2\,(n + m) + 1]$ (institutional matrix):

Table 1 Tabular form for analysis of the institutional environment

Conditioned acts	Stimuli					Limitations				
	s_1^k		…	s_n^k		l_1^k		…	l_m^k	
	Quantity of resources	Probability of obtaining $p(s_1^k)$	…	Quantity of resources	Probability of obtaining $p(s_n^k)$	Quantity of resources	Probability of losing $p(l_1^k)$	…	Quantity of resources	Probability of losing $p(l_m^k)$
o_1										
⋮										
o_k										

$$H_\Omega == \begin{pmatrix} o_1 & s_1^1 & \cdots & s_n^1 & p(s_1^1) & \cdots & p(s_n^1) & l_1^1 & \cdots & l_m^1 & p(l_1^1) & \cdots & p(l_m^1) \\ \vdots & \vdots & & \vdots & \vdots & & \vdots & \vdots & & \vdots & \vdots & & \vdots \\ o_k & s_1^k & \cdots & s_n^k & p(s_1^k) & \cdots & p(s_n^k) & l_1^k & \cdots & l_m^k & p(l_1^k) & \cdots & p(l_m^k) \end{pmatrix}.$$

From the standpoint of the interaction between the parties, each institution can be qualified in terms of translated behavior vector, the capacity, and variance of the institution, the probability of realization in the social system (institutional environme). Moreover, it's also possible to measure the strength of the institution's impact on the social system.

The behavior vector $B_{tr.H_\Omega}(O)$ translated by the institutional environment, can be calculated using the institutional matrix, data on the parties of the social system, and methodological approaches propounded by Samosudov [9]. But to facilitate the calculations, it is possible to calculate the average vectors of participants' behavior as $B_{tr.H_\Omega}(O) = \frac{\sum_j^{Q_\Omega} B_j(O_j)}{Q_\Omega}$, where Q_Ω is multiple participants of the system Ω.

Although, for a more accurate calculation of the translated behavior vector, it's necessary to know the status of the participant in the social system as well as the system in society, the behavior vectors of social systems and the intensity of interaction between parties and certain systems and with each other.

Institutional capacity $(M(h_k, H_\Omega))$ is the capacity of multiple participants whose component of the behavior vector is not equal to zero, i.e., the person knows the conditioned act set by the institution and its consequences (stimuli and limitations) and impartially estimates their probability.

The capacity of the institution can be absolute or relative. In the first situation, we estimate the number of entities with a nonzero component of the behavior vector and in the second one—the ratio of this multitude to the statistical universe. Depending on the tasks, the universe can be all people of a country or region, particular company or division.

The variance of a social institution is the scatter of personal estimates of stimuli, limitations, as well as the probabilities of their obtainment against the average value of these parameters.

There are individual estimates of the stimuli and limitations set by the social institution depending on the state of the system, participants, information flows. Also, there is an average interpretation of the institution as the result of averaged individual estimates.

Accordingly, for the qualification of a social institution, we resort to averaged interpretation and variance indicating at deviations.

For example, a person deals with a manifestation of the institution, that is, sees the act o_k and its consequences (the benefits and loss of resources). The vector of his behavior changes, this results in a conditioned act and alteration of the stimuli and limitations associated with the act. He can get this information when learning. Estimates may change as he interacts.

Committing an act, a person will translate a certain vector of behavior, which will serve as a guideline for other participants.

The probability of realization of a social institution in a given social system (institutional environment) is contingent on the features of the institutional environment. The more rigid the institutions, the more coherent the environment (no "gaps" and "white spots"), the more probable the realization.

From the point of management, **the strength of the institution's influence** is of particular interest. In the institutional environment, this feature determines the *time required for the corresponding component of the behavior vector of the person interacting with other participants of the system to reach maximum value.*

Let us outline the following prerequisites. Institutions affect a person, shaping his behavior; the strength of influence on people is different; an institution the action of which a person will be most often encounter in the social system will have a stronger impact on human behavior.

The institutional impact results in changing human behavior, the emergence, or alteration of the corresponding components of the behavior vector (probability of act commission). This value depends on human abilities, upbringing, desires, knowledge of information about the environment, etc.

Suppose that there is an institution h_x setting the conditioned act o_x. Then there is some maximum probability that a particular person will commit this act $p_{max.}(o_x)$, which will be formed under the influence of the institution for some time required for impersonal estimates of stimuli and limitations to reach the highest possible values in this system. That is, due to the impact of the institution h_x, the corresponding component of the behavior vector $p(o_x)$ will change from zero to the maximum value $p_{max.}(o_x)$ over a certain period T: $p(o_x) \overset{h_x,T}{\rightarrow} p_{max.}(o_x)$.

Moreover, this time depends on the properties of the system under consideration, its institutional environment and specific institution, and personal qualities. The deeper the interaction of parties, the more often a person deals with the facts of the commission or non-commission of an act, obtainment of information about its consequences. In addition, the smaller the deviations, the facts of non-occurrence of consequences, etc., which depends on the institution's variance, the less inconsistent information will be, the faster the person will form the best possible for this system impartial estimates of stimuli and limitations associated with the act. That is, the faster this component of the behavior vector reaches its maximum value.

Generically, both the features of the institution (institutional environment) and person impinge on the result of the functioning of the social system performance. The maximum value of the behavior vector components hinges on human perception of information about the stimuli and limitations of the conditioned act, as well as the resources available determined by (un)availability of information on the facts of no benefits in the act and the absolute values of the benefits/losses of resources. Perception stereotypes also take action.

For simplification, let us suppose that all information reaches a party to relations, that is, a person gets information without hindrances (without distortions)[2].

[2]In a strict sense, this is not the case—information may be non-delivered and distorted, incl. deliberately. But for consideration of the principle this fact is of no importance.

Then the strength of influence of institution h_k in the institutional environment H_Ω of the social system Ω is directly proportional to the deepness of parties' interaction expressed by the coefficient $k_{intens.}$, the institution's capacity $M(h_k, H_\Omega)$ and inversely proportional to its variance σ_k:

$$F_k(H_\Omega) = \varphi\left(\frac{[k_{intens.}, M(h_k, H_\Omega)]}{\sigma_k}\right)$$

It is crucial to assess the strength of an institute's influence solely in the institutional environment. Identical institutions under different conditions can have different effects on the behavior vector.

5 Findings

Thus, the institutional environment can be converted into digital using a matrix of dimension $k \times [2(n + m) + 1]$, and its impact should be recorded by the dependencies propounded by Samosudov [9, 10] and displaying the influence of information, including one received by a person from institutions on the behavior of parties. This allows estimating the influence of institutions on resource inflow, i.e., on the result of the company's performance.

Based on these dependencies, it is possible to form algorithms enabling the record of the institutional environment in the digital twin of the enterprise, as well as estimation of the impact of the institutional environment on the behavior of the system in the socio-economic space and the result of its performance. That is, to build simulation algorithms for the social system, which, in turn, will help simulate a model that can be used for management purposes.

The paper also discovered new lines of research on the social environment relying on the formalization of the institutional environment, as well as opened up new opportunities for simulation of the social environment.

6 Conclusion

The development of computer technology enables the digitalization of controlling actions in social systems, which will contribute to the functional stability and reliability of social systems. Therefore, it seems expedient to use the digital twin of the social system, presenting the sequence of changes in the system state (the path of its development).

Along with that, all the essential influencers of the system state should be formally characterized in terms of parameters. The influencers also include the institutional environment and its impact on the behavior of participants, which, in turn, embraces the distribution of resources under their control.

The employment of the resource-functional approach to the analysis of social systems, the development of the behavior vector concept, the techniques of a quantitative assessment of all types of resources involved in social systems, made it possible to identify the parameters of social institutions, formally characterize both individual institutions and their multitude (the institutional environment of the organization as a matrix).

This allows us to incorporate in the digital twin of the social system formal and informal institutions, including regulatory documents, corporate culture, stereotypes, and other phenomena affecting its state. When measuring control, this helps, firstly, to calculate the control effect with an account of the institutional environment impact; secondly, to predict the required changes in the institutional environment in order with a view to a control effect. Moreover, we can talk about automated and/or automatic calculation of documents, information, and material flows for adjustment of the institutional environment, a more accurate assessment of the corporate culture, and its impact on the company. Using the models presented by Samosudov [9, 10], one can assess the influence of changing institutional environment (for example, due to the adoption of new regulations) on the company's resource inflow.

New Expertise and Skills of Manager in the Context of Digital Business Transformation

Vasiliy M. Svistunov, Vitaliy V. Lobachev, and Siranush Manukyan

Abstract Modern business conditions more often require from managers broader digital vision of both current and future management of the company. Nowadays it's no longer enough for the manager to have the relevant expertise in certain functional areas of activity and broad managerial outlook. A modern manager should be able to initiate the entrenchment and utilization of advanced information systems and technologies in almost all of the business processes of his company. When writing the article, we have used the materials of a study conducted at some domestic industrial enterprises. Findings and main provisions are premised on the analysis outcomes of real practical implementation and utilization of corporate information systems. The results attained during the study, including the opinions of experts represented by a staff of industrial enterprises, were aimed at making up a list of prioritized fields of expertise and skills of current importance and interest that can help a modern manager to succeed in implementation and practical use of corporate information systems. The main finding of the study should be recognized making up such a priority list. The fastest achievement of the essential and sufficient knowledge within the above fields of expertise by company management is a possible solution to the problem of increasing the efficiency of modern IT use. The scientific novelty of the present article is that the demonstration of the professional behavior stated by the authors is designed to help the manager to lower the resistance of company staff to the implementation of modern information technologies.

Keywords Implementation · Knowledge · Qualities · Company · Corporate information system (CIS) · Staff · Resistance to implementation

1 Introduction

The more speeding up the digital transformation of all types of business without exception occurring against the backdrop of globalization inevitably results not only in stiff competition but also the complicated management procedures and tools. There is every reason to argue that the soundness of management processes and management tools have a great impact on the performance of a modern company. The aggressive digitalization relying on the highest possible and acceptable automation of production and business processes, as well as growing responsibility of management for a sufficient level of competitiveness to be achieved by a company, most often make the specialists debate what "new" professional knowledge and skills modern employees should have [11]. The range of new professional knowledge and skills needed by the manager as a person who sets not only the main goals and objectives of almost all business processes in his company but also determines structural and organizational changes required due to the development, implementation and wider dissemination of modern corporate information systems (CIS), which is the basic element of the digital transformation in any company [6] is the most hot-discussed topic.

Many experts mistakenly take the development, implementation, and practical use of modern information technologies by the company as a digital transformation of the business.

Today, digital transformation should be interpreted as a much more substantive category. Digital transformation includes multiple processes from the moment when the management understands the inevitable automation of business processes to the establishment of a brand-new company framework that fully meets the ongoing internal changes and ensures the smart use of the capabilities of CIS under implementation [2].

Consequently, digital transformation is the entirety of works and actions performed by company employees that are responses of the current management system to manager's decisions on automation of technical, technological, production, and management procedures and processes. The key among them are:

- decisions on the amount and terms of investments in modern information and automated technologies;
- revision of the range of products and services provided as a consequence of new technical, technological and information capabilities of the company;
- the achievement and practice by the company staff of the required professional knowledge to ensure highly productive performance work amidst wide automation of technical, technological and business processes;
- current structural changes in the company as a response to the CIS implementation;
- the elaboration of brand-new strategic directions of the company's development, which became available after getting an ability to collect (receive), analyze and

keep up-to-date information on the markets and players of the company's interest in much larger volumes than 5–10 years ago [9].

The scope of work to be done, and the practical experience of the leading world companies, indicate that the implementation and use of digital technology is a multifaceted and extremely complex, time-consuming and cost-intensive process. However, the final result achieved by the company from their practical use can and should pay off the investments [15].

By expert estimates, digital transformation is often accompanied by dramatic and often painful organizational and technical changes in the company. The changes that take place are treated by employees ambiguously. The team is divided into various groups from outright opponents to apparent supporters of the ongoing changes. The reasons can be unconfidence of staff in their future professional employability; the higher probability of retraining to ger the required professional knowledge and skills; serious concerns of possible changes in the system of remuneration and labor incentives; a severe situation on the labor market causing fear of job loss, etc. [12].

Under the current conditions, only essential and appropriate professional knowledge and skills among the company's management can provide the desired level of staff confidence in ongoing changes. The required level of confidence will reduce the employees' resistance to changes fetched by the adoption of digital technologies [10].

Modern digital tools and technologies can help the company to succeed in digital transformations only if they are intertwined with high expertise of the company's specialists, flexible and competent management. With that, a manager working in term of the digital transformation of a business should be a highly qualified specialist with interdisciplinary expertise such as management; personnel and HR management; modern technologies, including information ones, etc. [5, 7].

2 Methodology

The appropriate expertise and skills give a hope that a negative attitude of the company staff (certain groups or particular employees) to the ongoing digital transformation procedures will be significantly mitigated. Such a negative response, even more, complicates the implementation and practical use of CIS and lowers their practical efficiency. As many experts think, resistance should be considered as a reasonable reaction of employees to the digital transformation of corporate business processes. Resistance is explained by that the staff is not ready for ongoing innovations, often covering foundations of the company's activities and making employees participate in the modern lifelong learning model [3]. Besides, in the best case, the staff indifferently rake part in the implementation of advanced information technologies. In the worst case, the strategies of hidden dissent are often employed, often turning into a latent hindrance of changes [4, 8].

In the framework of the digital transformation of business, there is an urgent need to broaden the manager's digital overlook of company administration [14]. Expertise in such sectors as economics, personnel management, finance, marketing, and the broad managerial outlook is not enough for a modern manager. The manager should be able not only to initiate the implementation and use of modern information systems and technologies in the current business processes.

Now his duties embrace pursuing a uniform corporate policy in the new digital space and monitoring the fulfillment of projects on the implementation of effective digital platforms [1]. The main goal of the manager's activity can be defined as promoting the development of the company through the transition from conventional to innovative methods of work. When achieving the stated goal, the manager cannot but remember that innovative methods should meet both current and future needs of the company's transformation through more intensive use of modern information and communication technologies.

The digital transformation taking place among established stereotypes and prejudices of employees, more than ever, makes urgent the task to reveal the expertise and skills to be possessed by a manager who, on the one hand, intend to speed up implementation and effective operation of modern information technologies, and, on the other hand, can, if not completely overcome, but at least dramatically reduce the resistance to ongoing changes on the part of various categories of employees [13]. Overcoming evident or latent resistance should ensure the higher staff's lenience to digital transformation and ramp up dramatically the number of company employees who want to support and take an active part in the implementation and employment of the corporate information system.

The conducted study is devoted to the problem of determining the essential expertise and skills of managers that would greatly contribute to digital transformation in modern domestic enterprises.

A corresponding study was conducted by the authors in February-November 2019. The purpose of the study is set as to assess and sum up the opinions of participants of implementation or utilization of CIS in several domestic enterprises on the role and place of the manager in these processes as well as the list of fields of expertise and managerial skills required for the successful digital transformation of the company, and also overcoming the resistance of staff to ongoing changes.

At the first stage of the study, for the achievement of the stated goal, we carried out an analysis of the opinions of some domestic and foreign experts and advisors dealing with problems of the digital transformation of business processes. Summary and theoretical insight into gathered information allowed identifying the required fields of expertise and skills defining whether the manager achieves the expected result in the digital transformation of corporate business processes.

The outcome of the second stage is making up the priority list of fields of expertise and skills essential for a modern manager based on the practice of implementation and utilization of CIS by employees of domestic companies. To this end, we examined and summarized the opinions of experts representing nine industrial enterprises from five Russian regions (Moscow, Perm, Kazan, the Moscow and Tula regions). The experts

participating in the study represent enterprises that have been implementing or have already implemented CIS in their managerial activities.

In the framework of the stated problem, during the study, we have used an interview method with both open-ended and close-ended questions. Answering the questions, experts representing specific industrial enterprises:

1. had the opportunity, relying on their professional criteria, to add the lists proved at the first stage of the study with other fields of expertise and skills;
2. ranked, addressing their expertise and practice, lists of fields of expertise and skills established at the first and second stages of the study;
3. On the back of the summarized opinion of domestic and foreign specialists and advisors, their expertise and practice, we have drawn up priority lists of fields of expertise and skills that help a modern manager to carry out successful implementation and operation of CIS.

The course of the study did not admit possible external influence on the experts in the expression of their outlook on the problem under study. The answer options and their sequence did not also affect the expert opinion as far as each of them was provided with a random option of a sequence of fields of expertise and skills. The method under use allowed us to collect the initial data for subsequent analysis and evaluation thanks to open statements of experts who are most directly related to the implementation and employment of CIS in their routine professional activities. Subsequently, the initial data obtained in the questionnaire and interview were processed using quantitative and qualitative content analysis.

3 Findings

At the first stage of the study, we selected 14 fields of expertise and skills, most relevant from the standpoint of specialists and advisers, that help the modern manager to successfully implement and utilize CIS. In summarizing and theoretical understanding of resulting information that contains the opinions of domestic and foreign specialists and advisers, we took for the further analysis 7 most frequently and reasonably mentioned fields of expertise and skills that help the modern manager to effectively carry out the digital transformation of his company. The summarized opinion of specialists and advisers are presented in Table 1.

In the second stage, we surveyed 9 domestic industrial enterprises and interviewed 318 people, representing four categories of experts such as top managers (4% of the total number), middle managers (29%), lower managers (21%), and specialists (46 specialists).

The sample encompassed deputy directors of companies; heads of directorates, departments, and agencies; line managers; members of project teams and groups (specialists) who are participating or have earlier participated in project activities for the implementation and operation of CIS in their enterprise. The overall number of experts directly involved in the implementation made up 54.8% of the sample.

Table 1 The summarized opinion of domestic and foreign specialists and advisers on fields of expertise and skills that approach the manager to successful implementation and use of CIS

The following fields of expertise and skills help the manager to succeed in the implementation and use of corporate information systems (opinion of domestic and foreign experts and advisers)	
Fields of expertise	Professional skills
Strategic modeling	Operational thinking
Business communications	Strategic thinking
Computer simulation of objects and processes	Dynamic adaptation
High-potential digital platforms	Performance culture
NBIC—Convergence	Conscious decisions
Theory of collective thinking	Commitment to professional growth
Project management	Integration of time perspective

Experts who use CIS in their daily work routine is 45.2%. Interviews and surveys with a view to collecting initial information were anonymous.

The ratio of men and women in the sample was 82.0 and 18.0% respectively. The age of the sample is 21 years old (the youngest expert) and 71 years old (the oldest expert). The average age of experts is 53 years old.

At this stage, all the experts-participants of the above survey relying on their professional criteria added each list made up at the first stage with other fields of expertise and skills in an amount of not more than three; ranked fields of expertise and skills selected using the summarized opinion of domestic and foreign experts, advisers and experts. The findings are presented in Tables 2, 3 and 4.

An analysis of the opinion of domestic experts evidences that top managers referred to priority fields of expertise that help them in implementation and use of CIS, ones that make it easy to understand the potential of digital technologies ("high-potential digital platforms") and choose the most suitable option for their practical use ("strategic modeling" and "theory of collective thinking").

Specialists made their choice in favor of industries that develop a pool of knowledge that helps to unleash the potential of employees participating in the implementation and use of CIS to the fullest extent.

Table 2 The summarized opinion of domestic and foreign specialists and advisers on fields of expertise and skills that approach the manager to successful implementation and use of CIS

The list of fields of expertise and skills assisting a modern leader in the implementation and use of CIS (opinion of domestic experts)	
Fields of expertise	Professional skills
Team building	Responsibility for decisions and actions of the managed team
Change management	Creativity
Leadership	Social orientation

Table 3 The final opinion of domestic experts representing various categories of employees on fields of expertise of manager that facilitate the implementation and use of CIS

Expert category	Fields of expertise									
	Strategic modeling	Business communications	Computer simulation of objects and processes	High-potential digital platforms	NBIC—convergence	Theory of collective thinking	Project management	Team building	Change management	Leadership
Top managers	1	9	8	2	4	3	7	10	5	6
Middle managers	6	4	3	7	10	1	2	9	8	5
Lower managers	6	1	7	8	10	9	5	3	4	2
Specialists	8	5	9	7	10	6	1	4	2	3
Final priorities (1—max, 7—min)	7	4–6	3	8	10	4–6	1	9	4–6	2

Table 4 The final opinion of domestic experts representing various categories of employees on fields of expertise of manager that facilitate the implementation and use of CIS

Expert category	Professional skills									
	Operational thinking	Strategic thinking	Dynamic adaptation	Performance culture	Conscious decisions	Commitment to professional growth	Integration of time perspective	Responsibility for decisions and actions of the managed team	Creativity	Social orientation
Top managers	2	1	3	5	4	8	6	9	7	10
Middle managers	1	4	7	9	3	6	10	5	2	8
Lower managers	6	7	8	10	4	3	9	2	1	5
Specialists	4	5	8	7	9	1	10	2	3	6
Final priorities (1—max, 7—min)	1–2	3	7	9	6	4	10	5	1–2	8

The analysis of the opinion of domestic experts indicates that top managers prioritized strategic and operational thinking, the dynamic adaptation among professional skills that contribute to a manager's success in the implementation and use of CIS. Such a choice speaks about that preference is given to skills that allow the manager to foresee possible changes in the conditions and maintain the stability of ongoing business processes.

Specialists preferred professional skills such as the commitment to professional growth, responsibility for decisions and actions of the managed team, creativity. Such a choice witnesses that specialists are aware of the importance of their continuous professional growth and immediate response to changes.

4 Conclusion

As a result of the study, we made up based on the expert opinion a priority list of the most relevant professional fields of expertise and skills that help the modern leader to successfully implement and use CIS. The results of the summarized opinion of domestic experts are presented in Table 5.

The results attained in the study show that the successful accomplishment of works on the implementation and use of CIS is contingent on the appropriate specialized training and relevant knowledge of staff involved in these processes within the above-considered list of fields of expertise.

Table 5 The summarized opinion of domestic and foreign specialists and advisers on fields of expertise and skills that approach the manager to successful implementation and use of CIS

Ranking of fields of expertise and skills assisting to a modern manager in the implementation and use of CIS (opinion of domestic experts)			
Priority No.	Fields of expertise	Priority No.	Professional skills
1	Project management	1–2	Operational thinking
2	Leadership		Creativity
3	Computer simulation of objects and processes	3	Strategic thinking
4–6	Business communications	4	Commitment to professional growth
	Theory of collective thinking	5	Responsibility for the decisions and actions of the managed teams
	Change management	6	Conscious decisions
7	Strategic modeling	7	Dynamic adaptation
8	High-potential digital platforms	8	Social orientation
9	Team building	9	Performance culture
10	NBIC—convergence	10	Integration of time perspective

The second, no less important condition for success in using CIS is the willingness of staff to support the digital transformation of the company. The professional skills discussed in this article are those that will help the company staff to be productive both in the implementation and utilization of CIS.

Issues Related to Introduction of Modern Digital Technologies in Urban Infrastructure Management

Viktor M. Serov, Aleksandr V. Kozlovskiy, and Yuriy M. Tikhonov

Abstract This article is devoted to the study of modern trends in urban infrastructure management based on innovative digital technologies. The article provides analytical studies of current developments within national projects aimed at the establishment and evolvement of the urban infrastructure management system. The domestic and foreign practices of design and operation of Smart Cities and Smart Homes are examined and summarized. The authors assess the possibilities of introducing innovative developments in the digital environment for resource conservation, protection, and preservation of the environment. Some problems encountered by various participants in the implementation of these innovative projects and national programs have been revealed. High attention is paid to problem-solving approaches and techniques in the EU countries and megacities of Singapore and Beijing. The focus is put on energy efficiency in the construction and operation of facilities with regard to the foreign experience of application and implementation of innovative energy-saving technologies. The world development trends of urban infrastructure amidst rising energy prices are have been investigated. In the end, the authors have drawn up the conclusions and propounded the directions for a more efficient introduction of innovative resource-saving technologies as well as have made recommendations on improvement of the urban infrastructure management system.

1 Introduction

In the current context of the developing global and domestic economies, heed is paid to the preservation of the environment, adoption of resource-saving technologies in various fields of activity, enhancement of competitiveness at productions in general and enterprises in particular, as well as betterment of the population's living standards. In this regard, the implementation of national projects, such as "Housing and Urban Environment", for example, the national program "Digital Economy", aimed at establishing an adequate and productive system of urban infrastructure management, seems well-timed and currently important [1].

It is obvious that such high-profile multi-faceted projects embrace an entirety of various projects. For example, the implementation of project "Smart City" will higher the competitiveness of Russian cities in the world, lay down a productive management system of urban infrastructure and housing and utilities sector, which in turn will create comfortable living conditions, preserve the environment and refine the resource component of this economic management field [2].

These issues can be solved only through the introduction of digital and engineering technologies in urban and housing-utilities infrastructure.

2 Methodology

As follows from its content, the "smart city" is a coordinated system of technologies and innovations employed for communication with government bodies and provision of administrative services, in the transport network and traffic, energy power industry and water supply, healthcare, and housing.

The foreign experience of establishing and managing smart cities is positive. It foremost envisages provision with the technical equipment (urban safeguard and safety management system). The introduction of such a system has allowed saving municipal budgets on water consumption and urban cleaning in the amount of 42.5 million euros, replenish the budget annually by 36.5 million euros thanks to the creation of smart parking and new jobs [3]. For example, in Singapore, the institution of the smart city system is a national smart program with organizations and companies engaged in the development and implementation of digital technologies and telecommunication systems at the government level as participants. Smart transport, the establishment of energy and water-saving systems, waste removal and recycling systems, as well as the development of healthcare and public online platforms are among the technologies under consideration.

Russia has established the National Competence Center for project "Smart City" which will develop, implement, and promote technologies, equipment [4], programs aimed at higher digitalization of the urban economy. Moreover, it is expected to closely cooperate in the study and implementation of projects on international collaboration with respect to housing policy, urban infrastructure development, and the

management of resource-saving technologies, ones that foremost related to maintenance of Smart Cities' performance. For example, St. Petersburg doesn't divide the city into municipalities that facilitate the centralized provision of information and uses the principle of a single digital platform for integration of all urban infrastructure management systems into a single digital space, thereby creating a digital profile of the city. It is clear that the concept of "Smart City" should be aimed at the performance of municipal housing and social services and the comfortable life of the population. In this connection, the Smart Home concept seems to be an integral part of the Smart City system.

The practicability of using the Smart Home system is proved by comprehensive studies of a wide range of factors, one of which is the cost-effectiveness of the system components. The analytical studies gave an understanding of reasonable efforts to reduce the expenses for the resource component and discovered approximately 45% benefit under steadily growing energy tariffs [5].

Thanks to the Smart Home options, all life-sustaining systems are becoming more stable and durable. As for the introduction of such systems at the stage of new construction, the Smart Home system mitigate possible inconsistencies between the technologies to be introduced, which in turn not only extends the service life of the entire building and comfortability for residents but also lower the costs for installation of utilities system and monitoring devices. Russian law mentioned the need for entering innovative energy-efficient technologies in the construction and revamping the facilities. It's apparent that the Smart Home system meet these requirements to the fullest [6]. A "smart" house is taking control of climate, ventilation, light, all electrical devices, and a security system via remote control or smartphone. Sensors fitted in the house respond to any external changes (air temperature, time of day, presence of strangers) and allow the owner to manage the house from the outside; monitor the level of water and energy consumption through electronic devices, control equipment using the voice system.

To date, digital technologies being developed as part of Smart Home systems in Russia and European countries are intended to conserve resources. Developers aim to the economic efficiency of the systems to be introduced. Obviously, it relates to a large extent to energy-saving technologies as the resource is in the most demand.

Now the state is interested in the cost-effective energy supply of various industrial facilities and housing and private companies—in reducing the prime cost of delivered products. Energy costs are weighty expenditure item of companies, regardless of its activity whether construction or management of real estate facilities.

In Moscow, the heating season lasts 180 days on average and the heating spent is about 100 W/m^2. Innovations in energy conservation are designed to cut this indicator.

Together, energy-saving and energy efficiency in the construction industry and housing-utilities sector contributes to an adequate use of energy resources, the involvement of alternative sources of energy, and compliance with environmental requirements to keep the same level of energy supply.

In our opinion, the key point is that truly efficient energy consumption in the construction industry cannot be achieved without the interest and coordinated efforts

of all participants in the investment project. Since the introduction of energy-saving technologies requires an integrated approach at each stage of the life cycle of a real estate facility (Information Simulation of a Construction Project (BIM) [10]), we can present the following stages of the life cycle:

1. Design, i.e. setting the framework, components, interfaces, and other features of a system or its part (ISO 24765). This stage is resulting in the project as the entirety of models, properties or features described in a way suitable for the implementation of the system, including available or developing approaches to the implementation of the Smart Home system.
2. Construction, i.e. erection of buildings, facilities, and structures as part of the renewal of capital assets. This point also includes the refurbishment of buildings and facilities, their reconstruction, restoration, technical re-equipment and renovation, various forms of renewal resulting in innovatively equipped building "Smart home".
3. The operation, that is a set of works on maintenance, management, and renovation of a building (facility) allowing for installation and mounting of individual elements of the Smart Home system [7].

As a rule, at each stage various companies are pursuing their goals, that is, profit-making. Unfortunately, very often the management of companies is seeking to make a profit here and now without thinking about the possible, albeit the bigger, profit in the future. That's why the designers do not always find it necessary to introduce modern energy-saving technologies in the project since the Customer wants to cheap out on construction and refuse from expensive energy-saving technologies. This circumstance hinders the introduction of modern technologies.

Thus, if the participants in the investment and construction project cannot coordinate their actions, this function should be assigned to the government that should pursue a policy on the introduction of energy-saving technologies through appropriate legislative solutions [8].

The government should ensure the delivery of:

- energy-saving measures in an urban environment (management of all systems providing efficient use of infrastructure facilities, including waste disposal, parking, resource supply, the performance of various public healthcare services, social orientation, etc.);
- city-planning measures of energy conservation (that meet the climatic conditions of the mutual arrangement of buildings, the removal of through wind-forming spaces, etc.);
- city-planning solutions in low-rise construction, where the Smart Home technology can be applied to a greater extent.

Design engineering companies should take into account the general development path of the settlement in designing particular micro-districts or buildings and facilities. Designers should maintain the required level of energy conservation through:

- energy-saving architecture-planning, space-planning, and structural solutions;
- energy-saving solutions in the design of engineering systems.

After approval of the design by approving authorities, construction companies are admitted to the facility. At this stage, construction workers need to provide the execution of all design solutions. Otherwise, the slightest inaccuracy in construction works will reduce to zero all energy-saving solutions.

However, notwithstanding accurate theoretical forecasting and compliance with all the rules in the construction, a completed real estate unit can be found energy-inefficient. Such a situation is caused by a violation of operating rules. The service companies should regularly carry out energy audits of buildings for the detection or prevention of heat loss.

Germany is pursuing a policy encouraging the introduction of energy-saving technologies at the legislative level. Energieeinsparungsgesetz Act (Energy Conservation Act in the Construction Industry) prescribes that the energy consumption indicators of a building under construction must conform to the established standards.

To the end of enforcing compliance with these standards, participants in the construction process must use modern energy-saving technologies. At each stage of the project life cycle, decisions, both engineering and production, are made to reduce energy consumption.

Designers enjoy a wide choice of energy-saving technologies fitting the conditions of a particular construction (BIM-technologies in Design. What Are They and What Are Their Advantages?; Information Simulation of Construction Facility (BIM)).

The manufacturers of modern construction materials and equipment, seeking to access the market and augment the sales, carry out innovative activities to reduce the prime cost of materials production, and improve their technical features.

Besides, wages are high in Germany. In this regard, contractors also pay attention to the time spent by the worker for mounting these materials.

The entirety of all these conditions makes the Customer pay for the utilization of energy-saving materials. Meanwhile, the introduction of these materials will lower building maintenance costs and also will gradually reduce the cost of energy-saving technologies use [11–13].

3 Findings

Relying on the information examined in this article, we can conclude that the main constraining towards the introduction of energy-efficient technologies and materials in the Russian construction industry is inadequate government policy in the field of energy conservation and energy efficiency, as well as negligence of business in energy conservation as well as no mandatory energy consumption criteria of buildings and facilities. One of the indicative examples of state promotion of energy

conservation is Germany. Russia should develop its own strategy for the introduction of energy-saving technologies by adopting foreign experience and taking into account the peculiar Russian climate.

Today requirements for cost-effectiveness analysis as to the management of the energy supply and energy consumption systems of urban infrastructure facilities and industrial/residential buildings contain clear provisions and regulations for assessment of the economic efficiency of the energy system. In this respect, national law has to be clarified and, in some cases, altered [9]. One should work out a methodology for assessing the performance of measures taken to raise the interest of participants in the implementation of current innovative technologies and the development of new ones in a fast-paced digital environment. A methodological approach should stipulate the level of energy consumption for various types of buildings that will be influenced by electrical appliances or required electrical equipment. Then follows an assessment of the overall energy consumption and elaboration of measures for a possible reduction subject to specifications of electrical appliances and equipment and the scenario of their use. For example, in the EU countries, there have been developed certain requirements for energy and heat consumption within the design and installation of engineering networks in the construction of buildings and facilities. The alternative sources of energy and heat are also discussed. Such a methodological approach will help to assess the economic efficiency of decision-making depend on the properties of the energy source and electrical appliances and equipment under use.

4 Conclusion

Summing up, let us note that in Russia there are no well-defined approaches to the assessment of the introduction of innovative technologies in the systems for maintenance of urban infrastructure in general and individual real estate facilities in particular. In this vein, we suggest:

- taking advantage of innovative resource-saving technologies in the engineering system of the construction facility as early as the design stage;
- necessarily looking for provision of the facility planned for renovation or reconstruction with devices, sensors that will raise the operation efficiency of such buildings;
- reconsidering approaches to the assessment of efficiency of the energy generation and transfer by energy companies;
- providing well-defined investment financing models aimed at the establishment of an energy efficiency system by municipal authorities in the management of urban infrastructure facilities. With that in mind, for the efficient use of funds, one could carry out a regular energy audit to promptly identify “bottlenecks” in the general system for management of a city or a particular house.

Implementation of at least some proposed measures will necessitate the revision of approaches to business management within urban public utilities services.

Learning of Convolutional Neural Networks in the Tasks of Land Use Digitization Based on CUDA Technologies

Pavel V. Tereliansky, Alexey F. Rogachev, and Elena V. Melikhova

Abstract The purpose of the research is to explore the convolutional artificial neural networks (ANN) used in the tasks of land use digitalization to justify multi-year crop rotations, assess the state of crops, manage land reclamation, predict yields, etc. ANNs are a powerful tool of artificial intelligence, but its wide application is constrained by the limited speed response of central processors of modern electronic computing machines. This constraint can be surmounted through the utilization of parallel computing technologies. The use of CUDA technologies allows, depending on the ANN architecture and a set of macro parameters, dramatically reduce time input into network learning. As an environment of ANN development, we used cloud service Google Colaboratory based on the Python language, which involves a wide range of libraries for ML. We have taken into account the features of the physical principle of GPU operation, in which memory architecture is divided into DRAM and GPU memory in its streaming processors. A special unit of the system under development provides for building models and comparing the predicted parameter values with the given reference ones. Additionally, it is provided a unit for analysis of the parameters obtained from ANN to support decisions regarding the occurrence of adverse situations of crop cultivation (damage from pests, salinization, soil erosion). In the small ANN with up to 256 neurons in each of the layers, the time spent on the exchange between the GPU and CPU when implementing the CUDA technology is much higher than the time required for direct calculation, while it slightly hinges on the dimension of the input data streams. The findings make it possible to refine the

architecture, the macro parameters, and the learning time of ANN in the development of information-analytical complex for support of land-use task resolution.

Keywords Land use digitalization · Artificial neural networks (ANNs) · Convolutional layers · ANN learning · Parallel computing · CUDA technology

JEL Classification C63 · Q16

1 Introduction

Digitalization in land use tasks involves the employment of artificial intelligence algorithms and, above all, artificial neural networks (ANNs) of various architectures (Rogachev et al. [1]; Khilko et al. [2]).

Neural networks are intended to assess the state of crops, manage land reclamation, predict yield, and solve other problems relating to the processing of data bulk [3]. ANNs are a powerful tool for the practical implementation of AI tools, however, its wide application is constrained by the limited speed response of central processors of modern electronic computing machines. This constraint can be surmounted through the utilization of parallel computing technologies.

Information technologies of parallel computing have become an attribute of modern PC architectures thanks to faster task solution in various fields of the digital economy (Terelyansky [4]; Kostikova, 2017). The technologies under consideration are fully relevant to the tasks of learning ANNs used in various domains (Haykin [5]; Golovko [6]; Khilko et al. [7]).

Learning of ANNs requires considerable computational powers, therefore the so-called CUDA-technologies based on Nvidia Graphics Processing Units (GPUs) are used. Such video cards implement software modules written in the C family high-level language of Java-based Java engines and suitable for many problems, including the use of parallel streams in computations. CUDA-programming technology is implemented in a variety of Nvidia products (Cloud Services for GPU Computing. CUDA.NET. Available at http://www.hoopoecloud.com/Solutions/CUDA.NET/Default.aspx. Accessed 3 Feb [8]. It synchronizes the processing of information flows through shared memory, which speeds up the execution of operations with integer data (Frolov [9]; Boreskov [10]; Kundas [11]; Kundas [12]; Yarovoy et al. [13]). Although the initial application of the above CUDA technology was video accelerators for computer simulators and games, now this technology is also successfully used for calculations that do not involve visual computing graphic calculations (Kundas [11]; Shalkevich [14]; Kundas [12]) such as learning of ANNs with various architectures, matrix computing, solving linear equation systems and Fourier transforms, as well as in numerous application domains of economics and industrial production, including physics, astronomy, agricultural production, medical industry, etc.).

The architecture of typical graphic GPU-processors includes many streaming processors that are able to process 1,024 threads at the same time. It is focused on

Table 1 The features of modern graphics processors

Model	Memory capacity (GB)	Memory type	Cost ($)
RTX 8000	48	VRAM	5,500
RTX 6000	24	VRAM	4,000
Titan RTX	24	VRAM	2,500
RTX 2080 Ti	11	VRAM	1,150
GTX 1080 Ti	11	VRAM	800
RTX 2080	8	VRAM	720
RTX 2070	8	VRAM	500

memory modules (DRAM), the capacity of which depends on the model and can reach tens of gigabytes.

GPU that were popular a few years ago (for example, an RTX 2060 with 6 GB VRAM and a cost of about $ 350) are unsuitable for ANN learning and replaced by more advanced models (Table 1).

Nvidia's modern GPUs are based on ten-core SIMD processors that execute one-type computational instructions and simultaneously implement the same-type stream of instructions and process several data flows.

This approach fits for various scientific and applied tasks but requires special programming techniques that provide a larger number of execution units through their unification and simplification (Berillo [15]). The advantage of this approach is clarity and ease of learning by programmers, as well as usability thanks to the wide availability of the developed flexible and easy-scalable CUDA algorithms (Kalitin [16]). CUDA-technologies are widely promoted by the NVIDIA information website (see, for example, the contents of the website http://www.nvidia.ru.).

Along with that, the experts note (Berillo [15]) that some drawbacks of CUDA technology are the need for program code sophistication, a certain loss of performance in data exchange with the CPU, and the lack of software and hardware support for execution of recursive procedures.

In the field of AI tasks, CUDA technology is widely applied for resolution of time series forecasting tasks, recognition of graphic patterns, processing of agro- and geophysical studies' findings (Kalitin [16]; Khilko [2, 7]). The authors' research proves the data (Yarovoy [13]) estimating the application CUDA technology, which reduces the learning of ANNs about tenfold against CPUs.

At the same time, well-known software implementations of CUDA-technologies have disadvantages like:

- software modules are designed for specific GPU brands with disregard to the hardware capabilities of other types of new CUDA video cards;
- lack of open back codes for developers under a high cost of commercial products;
- possible loss of the potential benefits of increased productivity through the diminishment of the exchange rate between the RAM of the CPU and CUDA graphics accelerator.

Therefore, common recommendations on the use of CUDA-technologies for applied tasks, in particular, support for artificial intelligence, should be critically overviewed. In this vein, the following specific tasks should be tackled:

- verify the employment of CUDA-technology for learning of convolutional ANNs, in particular, ones aimed at productivity forecasting in crop production;
- obtain the most suitable values of the ANN macroparameters used by CUDA through experiment to accelerate their learning;
- cut the exchange of data between the GPU and the CPU in software during ANN learning.

For the assessment of the quality and forecasting of agricultural fields' productivity, we employed ANN with backpropagation algorithm learning (Haykin [5]).

The main difference between operations of the GPU and the CPU is an arrangement of works with in-built memory. A significant share of the CPU is constituted by the cache memory architecture. In contrast, most GPU is aimed at computations. GPU is characterized by a more complex and thoroughly documented internal memory architecture (Kundas 2011).

2 Background and Methodology

When building the ANN architecture, we took into regard the peculiarities of the GPU application to reduce the time of learning. As an environment of ANN development, we used cloud service Google Colaboratory based on the Python language, which involves a wide range of libraries for ML as well as C-family languages. We have taken into account the features of the physical principle of GPU operation, in which memory architecture is divided into DRAM and GPU memory in its streaming processors (Berillo [15]; Khilko [7]). Let's note that DRAM-memory includes several subclasses (local, global, constant, and texture). The memory located in the GPU streaming processors and having the maximum exchange speed involves both register and shared one.

The registers distributed in the code compilation determine the number of units executed by one multi-core processor.

When the available memory registers are not enough, local DRAM memory is preferable for the storage of variables. Interaction with which is distinguished by a higher level of latency, reaching several hundred cycles of access operations (Berillo [15]). Hence, high-dimension data should not be placed in the space of the mentioned registers.

3 Discussion and Findings

The flow chart of ANN developed for the software package is presented in Fig. 1. The function of activating neurons of the hidden layers f was taken in the form of *ReLU*. The ANN architecture provides for the concatenation of information flows from graphic (color images of fields) and numerical (retrospective data on productivity) inputs. The software package includes modules for the input of information, which also provides for storage and update of incoming information, in particular, remote sensing data.

A particular unit of the developed system will be responsible for the construction of models and comparison of the predicted parameter values with given reference ones. Additionally, it is provided a unit for analysis of the parameters obtained from ANN to support decisions regarding the occurrence of adverse situations of crops cultivation (damage from pests, salinization, soil erosion).

When studying the influence of the CUDA function configuration on the ANN performance, we analyzed recommended architecture parameters (Kundas [11]), in particular, the dimension of units (one-dimensional or two-dimensional), the number of streams in the unit, the sizes of the shared memory unit. As shown in the article (Golovko [6]), a comparison of NN computing time for the GPU and CPU containing 64 and 128 neurons in hidden layers allowed us to establish that CUDA technologies are well-founded for deep ANNs with over 32 neurons in the layers.

In learning deep ANNs, indicators of response speed have been compared with the duration of CPU-based calculations. The measurements were made for hidden layers of ANN and contiguous hidden neural network layers under the mathematical formula below (1):

$$Z_j = \mathrm{Fac}\left(\sum w_{ij}^T Z + T\right),$$

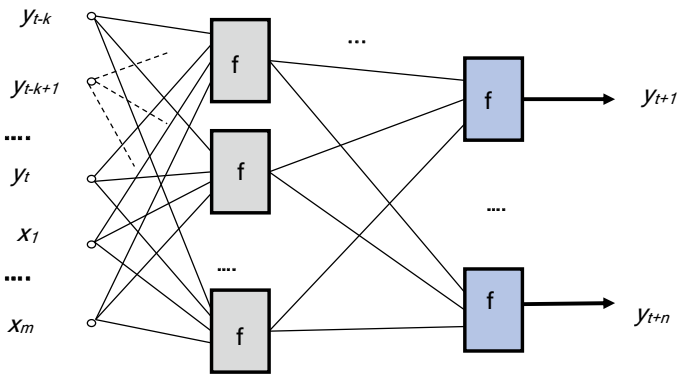

Fig. 1 Flowchart of the ANN under development

where Fac is the expression for the applied function of ANN layer neuron activation, for example, semi-linear *ReLU*;

W_{ij} is a weight matrix of interacting *i*-th and *j*-th layer neurons;
Z is the column vector of the *i*-th layer values in the analyzed ANN;
T is a column vector of the *j*-th layer values in the analyzed ANN.

The duration of calculations under the above formula when calculating in the implementation of the ANN learning procedure was determined in Python-based program for electronic computing machine using callback and the parameters of contiguous layers of neurons with different numbers of neurons in power 2 (16… 64).

The analysis of final time values revealed that the two-dimensional framework of the GPU is characterized by a higher response speed compared with one-dimensional. Hence, it makes sense to use 16 × 16 units with the same size of the shared memory. The choice of the optimal memory dimension is based on account of neurons number for the largest of them, with rounding upward to 2n, where the integer value n is taken from the range [1, 5].

During computational experiments in Google Colaboratory, we proved earlier received recommendation not to use large units of memory for layers with a relatively low number of neurons in hidden layers (Khilko et al., [2]), which negatively affects the speed of information processing. Therefore, we can recommend the size of the unit for the 1st pair (32 × 32) and the 2nd pair (16 × 16) in a network with a topology of layers containing 26-16-1 neurons.

Additionally, we can recommend exploring the use of combined CUDA technologies under joint utilization of GPU and CPU, particularly assess the practicability of CUDA use for layers with a large number of neurons from an adjacent pair.

4 Conclusions

The employment of CUDA technologies in the tasks of land use digitalization (justification of long-term crop rotations, assessment of the state of crops, land reclamation management, yield forecasting, etc.) when using the ANN configuration based on convolutional layers can dramatically reduce time input into network learning depending on the architecture and a set of macro parameters.

In the small ANN with up to 256 neurons in each of the layers, the time spent on the exchange between the GPU and CPU when implementing the CUDA technology is much higher than the time required for calculations. Besides, this time slightly correlates with the dimension of the input data. For the studied ANNs containing over 256 neurons in hidden layers, the duration of the GPU-based calculation is several times shorter although time expenditures grow due to the increased access time to the data. The number of neurons in each layer should be a multiple of the powers 2^n, $n = [1, \ldots, 5]$ of the number 2. The findings make it possible to refine the

architecture, the macro parameters, and the learning time of ANN in the development of information-analytical complex for support of land-use task resolution.

Concerning the Need for Digital Transformation of Cooperation Between the State, Society and Companies in the Field of Solid Waste Disposal

Jacques K. Mumba, Aleksandr A. Yakovlev, and Irina V. Milkina

Abstract This article is aimed at the identification of bottlenecks in the field of solid waste management and ways of their elimination with the use of digital technology. An analysis of the procedure for coordination between the state (represented by the federal and regional authorities) as well as municipalities with society and companies, which caused great communication problems. The most acute situation with both waste management and communication takes place in developing countries, especially in Africa and Asia. To a large extent, this problem has developed due to failures and sometimes a legal vacuum in the communication between the authorities, population, and companies. The good news is that similar problems, maybe of not so large scale. This situation may have already been solved by many Western countries. Digital technologies that have been developed by leading economies have already proven to be effective and will help change the current severe situation with waste management faced by many countries. The best practices of smart technologies have today a high potential as well as methods and outcomes of their use, which has been reviewed in this scientific paper.

1 Introduction

Throughout history, mankind has passed many stages as well as ups and downs. Each decade and rarely a shorter period brings various qualitative changes. Today, the world's population is on the verge of another transformation (this time it's digital one), which has already penetrated and even managed to root in particular fields. Emerging digital technologies make people's life easier and speed up management processes. There are many challenges before the modern society and the population of particular countries. Most of them have turned from presupposed threats into real ones particularly, the environment and its derivative management of solid waste (SW).

Almost half of the world's population does not have access to efficient waste management services. Waste storage at the specially designated territories remains the most common method of waste disposal in most large cities of the world. According to estimates of the UN Environment Program (UNEP) experts in 2012, around 1.3 billion tons of solid waste were collected in the world and by 2025 this figure will reach 2.2 billion tons [1]. To a large extent, higher waste volumes are associated with the underuse of technologies for the separation and recycling of industrial, defense, domestic, chemical, and other types of waste.

The issue of solid waste disposal is highly contentious in Asian and African countries. In particular, since 2018 the capital of the Democratic Republic of the Congo, the city of Kinshasa with about 12 million inhabitants has generated about 8400 tons of waste per day. Every day in the city, only 10% of the waste comes to city landfills the remaining 90% is piled in litter bins and boxes throughout the city, on the streets, in public places and on the territory of enterprises. There is no centralized system for the collection and disposal of waste.

A way out of this situation could be a more active and coordinated interaction between state (represented by federal, regional, municipal bodies and companies) [2]. Engaged in this activity are the state and private. The private companies are more common in most countries. The proliferation and inculcation of digital technologies can contribute to the resolution of the problem.

2 Background and Methodology

The methodological background of the study was constituted by general scientific methods such as analysis, synthesis, comparison, induction, deduction, grouping, generalization and analogy. Structural-functional and systemic methods were also employed.

To substantiate the assumptions, we used modeling and forecasting methods.

The theoretical background of the study served the fundamental provisions contained in the scientific papers of leading Russian, foreign economists and specialists in other fields of science.

3 Discussion and Findings

Both the state of the environment creating a comfortable space for life, the levels of illness, mortality and life expectancy is contingent on the procedure and depth of communication between the state and companies in the field of solid waste disposal. The state represented by authorized bodies set the game rules in any field of society, including handling and disposal of solid waste. In turn, legal and physical entities act within the established framework.

States have a much different approach to this issue. In some countries, this area is overregulated (mainly European states) and contributed by a high level of legal awareness. A clear separation of powers and the impartiality of the judicial system [3]. Other states have a legal vacuum resulting in chaos and criminalization of the economy (a significant part of the Asian and African countries) through corrupt relationships to a large extent [4].

An important point in the field under investigation is the ownership of the respective company. If the owner is federal (central authorities) especially when the company is located far from the capital, the governance will be constrained and the performance as a rule will be low. As for regional and municipal legal entities, the situation is far better.

State and municipal institutions function more transparently for their founder due to higher control [5]. In particular, it concerns a public institution [6]. In some countries, including Russia, a significant number of state institutions communicate on a variety of issues via special information systems which allows for the acquisition of information in real-time.

Joint-stock companies are obliged to disclose information on the Internet. Its scope strongly correlates depending on the state, but anyway there is a minimum that is enough to get a fairly complete overview of the company.

In all fairness, speaking about what way and how effectively the communication between the state and companies, we should bear in mind that it depends not only on the continent [7] or the country of location [8] but also the industry of company's operation.

This study pays heed to developing countries and ones with the transitional economy as far as where the problem of solid waste disposal persists for the authorities.

The population of developing countries especially, low-income urban residents suffers the most from higher volumes of solid waste in large cities that are often poorly governed by the municipal authorities. In countries with low living standards, more than 90% of municipal solid waste is often disposed off in unregulated landfills or openly incinerated. Such practices have severe implications on health, safety and the environment. Improper state and municipal management of solid waste provides fertile soil for disease vectors which contributes to global climate change due to methane production and can even lead to the growth of violence in the cities [9].

As noted above, in African countries the situation with the disposal of solid waste is extremely complicated. This problem is the most likely felt in cities with a population

of one million people. One of them is Kinshasa, the capital and largest city of the Democratic Republic of the Congo. Kinshasa has an area of 9965 km^2 and is located on the left bank of the Congo River. The population is growing steadily. Thus, it has increased from 1600 inhabitants in 1920 to over 12 million to date. The population density is 1211 people on km^2. One person makes from 0.8 to 1 kg of SW per day depending on the living standard.

The problem is unresolved in the megacity for a whole range of reasons, such as the lack of population's initiative and political will. At the same time, the population and consumption of livelihood keep on growing, uncontrolled urbanization, the establishment of anarchy and industrialization. Waste management mechanisms are out dated and stems from the colonial era. The annual volume of municipal solid waste in the city of Kinshasa is estimated at 2 million m^3.

It should be noted that the legal part of the solid waste disposal market accounts for less than 20% of waste in 9 out of 24 municipal entities from where the solid waste is delivered to the municipal landfill site. The rest (since 2010 it's over 80% of waste) is disposed off in public places and city rivers, which are commonly regarded as potential dumps [10].

Neither private nor state companies are involved in the above processes. They are either organized and controlled by representatives of the shadow economy or in some cases they're illegal.

If dramatic measures are not taken, such a state menace can lead to disastrous consequences. The number of uncontrolled landfills with a high potential impact on the environment and human health will increase.

In addition to the aforementioned, we can list other reasons that gave rise to the present challenging situation in the field of solid waste disposal.

The legal framework that has existed since colonial times have become obsolete and can hardly be revised and updated. The public administration system also in the field of solid waste management was established in the same period which consequently has the same flaws.

The laws governing the activities of legal entities is piecewise and is unregulated in many areas. On the one hand, it hinders the work of companies especially with private capital. Nevertheless, it is sometimes difficult to even find a regulatory act under which a company should function. There is a critical shortage of information essential for the company's operation. The integration of state and municipal bodies into the Internet space is extremely slow.

A shortage of regulatory acts could be overcome if state bodies (municipal ones in a perfect scenario) were obliged to publish full texts of them on the official website in a special section entitled the same way for all bodies.

Along with this, there is no a few official data on the location and description of solid waste landfills in the city of Kinshasa. As a result of this, for state and municipal bodies as well as public it's hard to control the disposal of solid waste.

As far as the authorities are not able to gather reliable information on the volume of solid waste and its circulation, it seems unfeasible to work out a strategy for efficient waste management.

If the more or less reliable information possessed by authorities was published on the Internet, this would enable the residents to take part in the discussion of this problem.

A significant measure could spring up if the authorities would design an Internet portal for placement of information on waste to be supplemented by residents and representatives of companies involved in the solid waste disposal.

The lack of crowdsourcing technologies in this area dramatically hamper the modernization of an ineffective solid waste management mechanism. Similar tools are employed even in some cities of developing countries.

Smart technologies are rapidly developing and making pioneering changes to the governance of the country in general [11]. A city or company in particular [12], as well as communication between them [13]. They make the operation of municipal services not only more efficient but also transparent and understandable for residents. In the localities of Europe and other continents where smart technologies have been introduced, the performance of local authorities and companies also rose and brought them to the next level of digital transformation.

The implementation of a special application designed to collect, manage and review downloaded data on waste can make a positive contribution. This application could contain other useful functions. Adaptation to different operating systems would help to quickly promote the program not only among consumers but also companies involved in the disposal of solid waste as well as bodies supervising the activity of such companies.

Today, many city residents agree that there are environmental risks to life in a city and the need for continuous improvement of life quality of the urbanized population. One of the main lines is the disposal of solid waste and control over it.

In many developed countries, owing to digital technology residents and companies reconsidered the issues of urban space usage. Involvement and influence (direct and indirect) of new physical and legal entities on urban management, includes, waste disposal which creates a synergistic effect and even more improves the urban environment.

Digital technologies can be implemented in different ways. One of the examples is a New Jersey volunteer project. They are actively introducing a new web-application based on a geographic information system for reporting and mapping the cases of illegal landfilling throughout the state. The app was designed by the New Jersey Department of the Environment using Esri ArcGIS technology. It allows users to identify the type of waste such as construction or hazardous materials and the size of piles, such as small, medium or large etc.

Another example is crowdsourcing analysis recently conducted by the Institute of Environmental Sciences in the Democratic Republic of the Congo. As a result, the public and government bodies were provided with reliable data on the existing waste landfills in the city of Kinshasa. The database contains landfilling points in the city of Kinshasa [14]. Among them are 61 public and 151 illegal dumps. Their total volume is 587.920 m^3.

According to data provided by analysts of the solid waste project, the waste mainly consists of plastic organic materials, follow by metals and glasses. The observed landfills are generally located next to roads, houses and a river.

Innovative and effective management of solid waste is a solution to the problem of inefficient route planning and conventional methods of solid waste management, which include the waste collection in urban areas.

In particular, the city of Kinshasa could invest in automation based on the Internet of Things (IoT) and smart sensors together with advanced capabilities of cloud computing services. It's high-potential for the establishment of real-time communication with transport and other units of companies involved in the disposal of solid waste.

4 Conclusions

In a nut shell, we can state that solid waste management is not just a severe problem but a global canker both from environment, healthcare and other points of view. Unresolved environmental problems hamper the economic development of the state and the intellectual growth of the population.

Digital technologies are capable of at least not solving the problem but moving the situation forward. Open and integrated management models (mechanisms) are always more efficient. Therefore, the introduction of tools that make solid waste management more transparent should be prioritized by all tiers of authorities in the whole world. The best solution algorithm is the inculcation of digital technologies and the adoption of progressive experience in this field.

Visualization of Corporate Digital Management

Aleksandr V. Raichenko, Viktor G. Antonov, and Yuriy V. Lyandau

Abstract In this article, the authors considered the visualization of technology for building a management system for the innovative start-up "SPERO", which implies the organization of access to the technological platform for calculating indicators of IVF procedures for own and partner clinics. In the article, the visualized models of business architecture of top level, chain models of value creation, models of financial streams are presented. The authors emphasize that the effective construction of activities is possible through the correct construction of the business architecture of the project, which is actively promoted by visualization.

Keywords Organization management system · Digital organization management system · Business architecture · Visualization of business architecture

Jun Sun's research suggests a technology for text analysis of documents, which is the basis for visualization. A frequency algorithm has been optimized to automatically extract this key information from text, taking into account the characteristics of engineering texts. Key messages extracted from report text as keywords/terms were visualized using a tag cloud algorithm.

In research, intelligent text analysis and visualization technology is used to extract valuable information hidden in the dense and abstract text of a construction report and process it in a simple and intuitive graphics. This structure allows managers to quickly understand and make more informed decisions based on key information. For automatic extraction of such key information from the text, the frequency algorithm of the term "frequency-inverse document" was optimized taking into account the

characteristics of engineering texts. Key messages extracted from the text of the case study report in the form of keywords/terms were then visualized using the tag cloud algorithm. The questionnaires filled by construction managers have shown that the proposed system of information visualization can facilitate fast and informative access to key design information. The framework thus reduces the workload and time required for construction managers to ascertain the status of their projects and take action.

In the studies the questions of how the heads of enterprises make the decision on introduction of new technologies are solved. We have found that the limitations of perception of new technologies are a barrier to innovation. In contrast, factors of easy perception of the new technology will stimulate innovation [1].

Visualization of activities is relevant for researchers in terms of safety [3]. This growing trend encourages researchers to develop new safety models based on information visualization. These technologies, however, do not address defense solutions.

Balakrishna [4] states that effective information understanding is possible thanks to the generation of data from various devices, communication protocols and data formats, which are enormous by their nature. This is a significant challenge for application developers of Internet of Things to make data compatible. Existing approaches lack well-defined standards and established tools to address semantic compatibility in applications Internet of Things and Big Data. Sivadi Balakrishna offers an approach to big data solutions for healthcare applications where doctors and patients can interact effectively and conveniently with each other. Internet of Things and Big Data are the dominant technologies for healthcare applications.

Modern digital technologies actively penetrate into management activities and allow to form systems of digital management of organizations.

The system of digital management of the organization is a set of interconnected elements, united by a digital platform, through which the organization and implementation of activities using modern digital technologies are implemented (artificial intelligence, Big Data, blockchain, etc.).

Let's analyze the system of digital management of innovative medical startup "SPERO". SPERO is the first project in the world that shows a 2.5 times higher level of efficiency (70–75%) of IVF procedures compared to the industry average [5].

The concept of the SPERO project involves providing access to a technology platform for the calculation for own and partner clinics. The availability of own clinics is conditioned by the fact that own face-to-face patients are the main source for gaining a complete picture of the market presence. Besides, on the basis of own clinics it becomes possible to solve such problems, as: adaptation of patient treatment protocols, enrichment of training samples with fresh data, training of new specialists.

Interaction with the technology platform is planned to be carried out through a web interface that allows downloading the full clinical picture of the patient, which includes anamnesis, test results, results of studies, and more. Downloaded data in anonymous form are sent to the SPERO own server for making calculations in a short period of time (at the moment the speed of one calculation corresponds to 2–3 min,

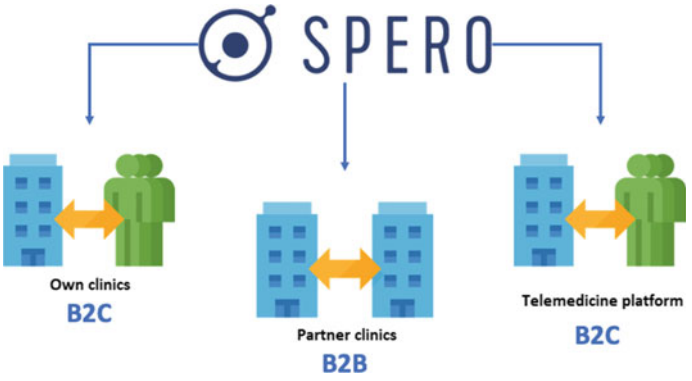

Fig. 1 SPERO areas of activity

but in the process of technical support and constant updating of the technological platform the time for processing one request is significantly reduced).

In the process of developing the entrepreneurial project, it was decided that in order to ensure maximum availability of services and to cover the maximum number of potential consumers, activities will be carried out in three main areas (Fig. 1):

- own SPERO clinics;
- partner clinics;
- telemedicine platform.

Own clinics are meant as a B2C solution (Business-To-Consumer). In the general structure of activities, own clinics are a certain foundation on which further development of the project will take place. The main advantage of own clinics in the context of the whole project is the ability to quickly attract the primary flow of patients to the clinic without incurring high marketing and advertising costs, since at the moment there is already a certain list of people who would like to use the SPERO technology. In addition, if there are a large number of successful treatment results, own clinics will serve as an irrefutable proof of the advisability of using the SPERO technology in future partnership agreements with other clinics.

It is important to note that the control at all stages of the process of diagnosis and treatment of the patient allows to make the most objective clinical picture, which provides the highest possible accuracy of calculations and quality of recommendations issued in the report. The peculiarity of implementation and control of activities in own clinics contributes to the optimization of methodology for working with the SPERO platform. Such methodology is extremely necessary due to the fact that on the basis of own clinics it is planned to organize a specialized training center for new specialists to work with the technology platform. The activity of the training center will be aimed not only at training its own specialists, but also at training specialists from those clinics which it is planned to enter into partnership relations with. One of the potential advantages of the training center is the opportunity to get acquainted with the principles of the technological platform of potential patients of SPERO

clinics, which will characterize SPERO as an open and transparent organization—in the future this will have a positive effect on strengthening brand loyalty.

Partnership with other clinics is meant as a B2B solution (Business-to-Business). This direction was chosen as the main direction for business scaling, as the process of opening own clinic is quite long and expensive, and often it will be irrational.

For example, in order to provide access to SPERO technology to residents of remote regions with small populations, but where there are already a number of clinics involved in the diagnosis and treatment of infertility, the construction of an own SPERO clinic will not be able to provide sufficient patient flow necessary to reach the optimal cash flow, which from an economic point of view will lead to losses and closure in the future. At the same time, a partnership with an existing medical institution on the market in this region will allow to avoid capital investments in opening an own clinic, but at the same time to cover another region with SPERO technology and thus strengthen the effect of presence on the global market.

The telemedicine platform is the final line of business that allows maximizing market coverage. The expediency of such a model is due to the fact that among people facing the problem of infertility, there is a certain percentage of those who are not yet ready to go to the clinic for direct treatment for various reasons (high cost of treatment, large geographic distance from the nearest center where infertility is treated, etc.), and in terms of B2B: There will be a certain percentage of clinics that are interested in SPERO technology, but plan to use it only in exceptional cases, so it will be advisable for them to access it only as needed.

When developing new entrepreneurial projects in the digital economy today, special attention is paid to the construction of business architecture, as it allows to visualize the logical relationship between the mission, vision, internal processes, their participants and development strategies, thus creating a significant competitive advantage over other projects whose vision is limited only to an idea. The key to a competent description of the business architecture is the graphical visualization of the main business processes using different models. At construction of business architecture of enterprise project SPERO the decision to describe the following models was accepted:

- value chains;
- top-level business architecture model;
- infrastructure model;
- financial flows model.

Since SPERO's activities have 3 main areas (own clinics, partner clinics, telemedicine platform), the value chain was reviewed for each of them.

The first area of activity is infertility treatment in conditions of own IVF clinics (Fig. 2). For greater visibility of the process, it makes sense to consider the primary treatment of a new patient in the clinic. At the first stage, the administrators of the clinic make a new appointment with the doctor, then a new medical record of the patient is created in the information system of the clinic, where information about the patient's history, information about all the studies conducted, as well as the treatment program itself will be recorded at subsequent stages.

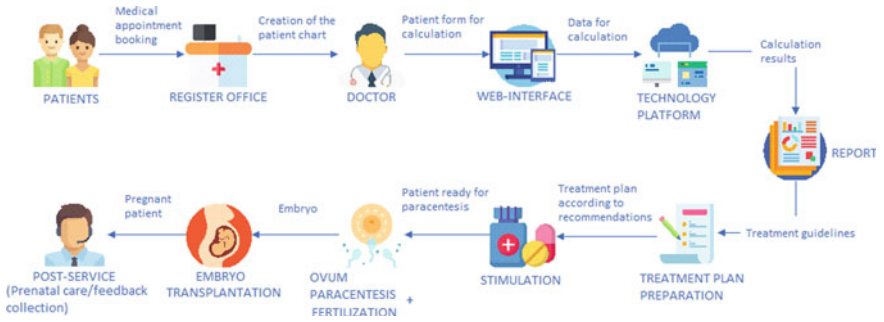

Fig. 2 Own clinic's value chain

Fig. 3 Partner clinics' value chain

During an appointment a doctor collects all the necessary information about the patient for making a diagnosis and drawing up a treatment plan: anamnesis, biometric indicators, results of laboratory tests, history of previous treatment, and others. All information collected by the doctor also includes data needed to calculate an individual IVF date and collect recommendations. This data is recorded in an anonymous format using a dedicated SPERO web interface, which is then sent to the SPERO technology platform, which consists of the server part itself and an algorithm based on machine learning that performs the calculation.

The calculation report, which contains information about the optimal dates of the manipulations within the treatment protocol and individual recommendations, is sent back to the attending doctor, who corrects the proposed treatment plan according to the report received. The treatment is then carried out.

The final stage includes either prenatal care directly at the SPERO clinic if the pregnant patient wishes, or collecting feedback and receiving reviews on the work.

The next area of activity is working with partner clinics (Fig. 3). The direct client in this process for SPERO is the partner clinics, which treat their own patients using a key technology. To interact with the technology platform for partner clinics, a special web interface is provided that allows uploading anonymous patient data to the SPERO technology platform. The calculation and reporting phase with results and recommendations in each chain is done in the same way. In the final stage, the attending doctor from the partner clinic receives a report from the SPERO platform, meaning that the doctors of the partner clinics may or may not follow the recommendations specified in the report. This means that for them, the report from our platform is more of a reference base than a strict treatment plan to be followed.

Fig. 4 Telemedicine platform value chain

The third area is the telemedicine platform. The direct client here, as well as for own clinics, is the patient, only with the difference that the access to the technology platform is performed independently (Fig. 4). At first, a potential patient is registered on a special resource (site or a specialized application), after registration a patient questionnaire is filled in.

At this stage, all necessary information is collected directly by the patient. The completed questionnaire is then sent anonymously to the platform for calculation and report preparation with expected dates and recommendations. The report received as part of the telemedicine platform services cannot be used for making a diagnosis or prescribing a treatment course. Thanks to this report, a patient can only assess the potential state of their body and complete their clinical picture with such a study. In case the patient then decides to contact the clinic with this report, they will have to go through the calculation phase again.

The next stage of building the business architecture of the SPERO project is the visualization of the top level model (Fig. 5), which is based on all activities considered by the value chain. In this model of value chain, the directions of activity jointly represent the main processes of the entrepreneurial project, which are centralized around the SPERO technology platform, that calculates the optimal dates for IVF.

As can be seen from the model, the main administrative function is performed by the CEO, who controls the results of the main activity, on the basis of which he/she provides reports to business owners, who manage the strategic direction of the entire project. The CEO manages the project's core team, which consists of financial, operations, medical, scientific, technical directors and a lawyer.

The project team performs the function of ensuring optimal and uninterrupted implementation of the main processes of the project activity. Each of the team members is assigned with a function within the framework of the processes under their control.

Financial director: provides uninterrupted money flow at the main stages of the project; controls the costs produced; analyzes and prepares a report based on the main project metrics; develops financial models of the project; at the initial stage of the project performs the function of developing and providing potential investors with a model of unit economics of the project.

Medical director: provides control over the activities of medical personnel within the framework of own SPERO clinics; deals with issues of life safety of both personnel and patients; takes part in adjusting and developing the methodology of interaction with the project platform.

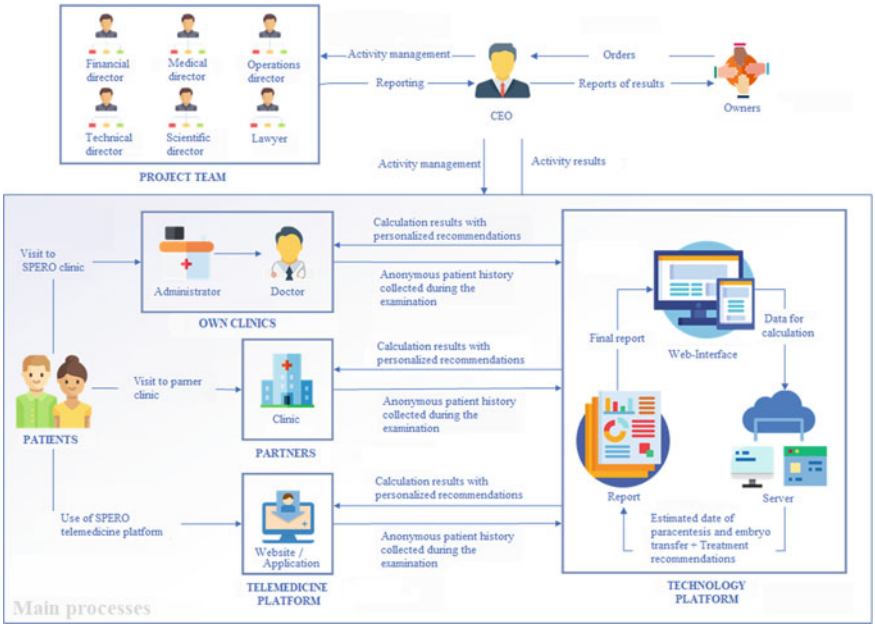

Fig. 5 Top level model

Operations director: provides control over the implementation of the main business processes of the project; SPERO provides logistics of necessary consumables for all necessary manipulations within own clinics; exercises direct control over CRM.

Technical director: the main functions are to control the uninterrupted operation of the technological platform, ensure platform security and confidentiality of transmitted data, the process of optimizing the calculation algorithm, development of new editions of the program code.

Scientific director: deals with the analysis and optimization of the logic of the algorithm of the technological platform, is engaged in increasing the efficiency of the algorithm, setting and testing new hypotheses.

Lawyer: deals with legal support of the project, distribution of rights among investors, support of investment transactions.

The technological infrastructure of the project has two main elements:

- Complex automated system for managing internal data flows;
- The server providing interaction of the whole technological platform, web-interface of access to the platform, support of the project site.

As a control system of internal data flow, a complex solution is used, designed specifically for the organization of the information system of treatment and prevention facilities, developed by medesk (Fig. 6).

A large number of interconnected modules of the medesk software solution will allow to perform the following functions:

Fig. 6 Medical Information System structure

- making an appointment with the doctor + online appointment;
- ensuring uninterrupted operation of the registry and automation;
- organization of the doctor's workspace;
- payment and billing process management;
- patient database maintenance;
- maintenance of electronic patient records with print capability;
- setting tasks for employees;
- ensuring the security of processed data through regular backups;
- patient management with a CRM system;
- data collection and preparation of an automated performance report.

Proceeding from the described functionality of the Medical Information System it is possible to draw a conclusion that within the limits of one software product all necessary internal functions in the organization are provided.

The main advantage of medesk software is that it supports integration with other software, so it will allow absolutely painless process of interaction between web-interface and doctor's workspace, while maintaining confidentiality.

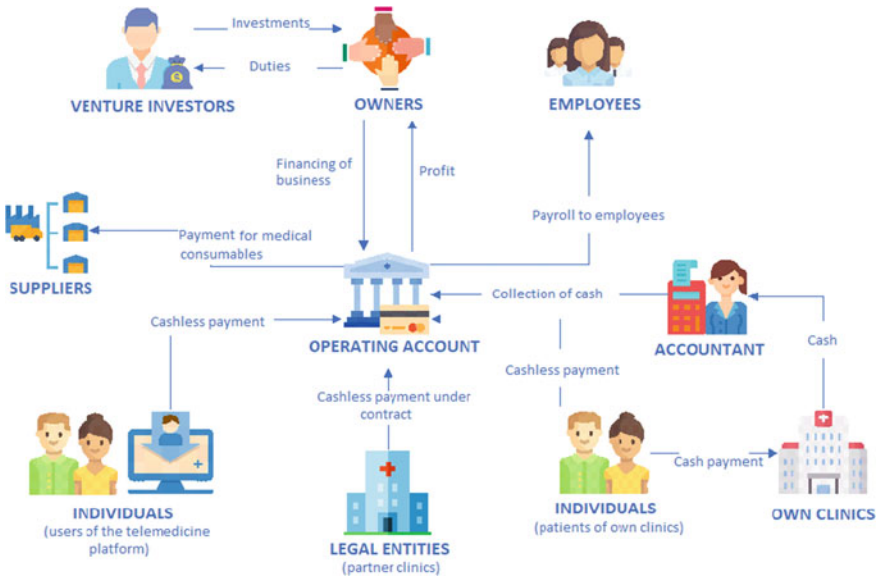

Fig. 7 Financial flow model visualization

The final stage of building the SPERO project business architecture is the visualization of the financial flow model (Fig. 7). This model is necessary in order to characterize the process of creating value for the business owner in terms of converting users of services into direct profits for the owner. As it is possible to notice from the financial flow model, the own way of payment is carried out for each of directions of activity. For example, patients at own SPERO clinics can pay for their services either in cash or by card. In the first case, cash is collected before it is deposited into the current account. Collection of cash is done on a regular daily basis.

The result of the collection procedure is the transfer of funds to the current account of the organization. In the second case, payment is made through the terminal with the help of a card, so the money is immediately credited to the current account of the organization. Users of the telemedicine platform pay for services by means of non-cash transfer via online cash register on the website or in the application, depending on which interface of interaction with the platform they have decided to use. In the two cases considered, payment for services was made by individuals, in cooperation with partner clinics, payment for services of technological platform is made by legal entities. In this context, payment is made by transferring funds from the counterparty's current account to the organization's current account in accordance with the rules established in the concluded partnership agreement. Once the revenue from the services has been transferred to the current account, the stage of fulfilment of obligations, such as payment of salaries to employees and payment of necessary

consumables to suppliers, begins. After the basic payments are made, the business owners have the net profit in their current account. Holders dispose of profits at their discretion: they can pay out dividends to themselves, or refinance the resulting profits.

System Approach in Digitalization of Management

Nikolay G. Malyshkin, Natalia V. Mikhalevich, and Elena V. Nikitina

Abstract The development and widespread dissemination of digital technologies in almost all sectors of the economy and management has led to radical changes in the nature of project management, which in turn has created new problems in organizing project activities. An analysis of the impact of digital technologies on modern business processes in the sectors of material production and services made it possible to identify changes in the functions and knowledge requirements of system theories. This necessitates the search for new approaches to project management, changes in the forms and content of project activities both inside the company and at the level of public project management. The authors consider many concepts of system theory in the work. The lack of a single concept of the system leads to the absence of a standardized definition of this concept, equally understood in various areas of project management. The authors examine the evolution of the definition of the meaning of "system". It's noted that the theory of systems can be defined as the totality of an object or subject of study of system theory, as well as the methodology and methods of the management process. The studies conducted by the authors indicate that, in connection with the digitalization of the business, it's important to revise project management taking into account the methodology of system approaches. The authors propose a system of measures to ensure the development of the corporate project management system in the organization in response to the challenges of global technological changes and the complexity of production and public relations, which leads to a noticeable lag in the methodology for the formation and application of new terms in digitalization.

1 Introduction

The systematic approach has shown its strengths and weaknesses on various practical examples. As it emphasized in the literature, a systematic approach to management is a modern phenomenon, the occurrence of which shouldn't be surprising, since currently complex technological processes are inherent in production.

In fact, if you really look at things, you can quite definitely say that the modern "systemic movement" still doesn't have a clear and concrete program.

However, skeptical conclusions shouldn't be drawn regarding the theory of systems and its future. Currently, the main question isn't whether a theory of systems is possible, but how to construct such a theory. It's a fact that great success is evident in this area, that the systemic ideas and methods used in scientific research and in practice have made significant progress.

Experience shows that not one of the currently existing versions of system theory fully satisfies the requirements. These versions contain advantages and disadvantages, which, taken together, don't allow to give preference to any of them. That is why, in this regard, some authors emphasize that during the analysis they don't adhere to any special version of the theory of systems. One of the reasons for the weakness of L. Bertalanffy's concept noted in the literature is that the general theory of systems began to be created as a formal deductive system and didn't contain any applied developments.

Among specialists, a significant reason for the limitations of some modern interpretations of systems theory is the fact that these concepts draw attention to the formal and mathematical problems of describing systems and the content, basis haven't been satisfactorily developed yet. That is why the using of a formalized apparatus in them turns out to be extremely limited, inadequate to the tasks that system research and the general theory of systems are designed to solve. In this sense, experts believe that the construction of a formalized system research apparatus directly depends on preliminary successful work in the area of studying the content of a systematic approach [1–8].

This makes it possible to consider ideas (the theory of systems in a modern form) and use them as methodological prerequisites for solving certain problems.

Now it's virtually impossible to analyze all definitions of a concept (system), the number of which is increasing. At the present stage, incorrect practice is increasingly being asserted, in which, as a rule, all authors, who develop system problems, use their exclusive concept of this term.

Of considerable interest is the evolution of the search for a satisfactory definition of the term of "system". L. Bertalanffy considered a set of elements that enter into

interaction under the "system". This definition was later criticized for the fact that not every system has an interaction between elements. From such positions, A. Hall and R. Fagin define the system as a set of elements. There is relationship between them, not interactions.

This definition is also vulnerable, since here any combination of objects is called a system. These shortcomings were overcome by V. N. Sadovsky, who, considers the totality of the set of elements intertwined with unique connections and relationships within a unique structure under the system. Here it's necessary to make one clarification that the element acts as an indivisible component precisely with this dismemberment method [9].

The relationship within any system is the matrix with help of which the components of the system are combined into one indivisible whole. When building a control system, much attention is paid to the compatibility problem.

Compatibility is a commonality between components with respect to certain properties. Compatibility is something that enables interoperability between these components [9].

Every system of organically composed elements is characterized by non-standard behavior and a high degree of influence of new ideas. Systems function and develop in a specific environment, which is a collection of all objects whose changing properties affect the system.

Many authors aim to build a formal theory of systems. Others point to the need for cybernetization of systems theory. At the same time, all these experiments are inspired by one constant circle of ideas, among which the idea of synthesis is central [10].

The synthesis problem is one of the fundamental ideas of systems theory since its inception. This theory was established by overcoming the atomistic view, which had deep roots in almost all sciences. The essence of the concept of "system" is the idea of synthesis of integrity as a property of the system.

2 Methodology

The systematic approach throughout its entire life cycle was system-differentiating and system-integrating. Basically, these two approaches don't contradict each other; they act as varieties of a systematic approach. Therefore, we have a certain invariant, which, when it activated, functions in accordance with the requirements of the methodology for studying systems.

This is a requirement of the integrity, compatibility of components, horizontal and vertical decomposition of systems. No matter how great the specificity of the approaches being considered, no matter how peculiar the situations, in which they can be used, it's necessary to act in accordance with the laws of a systematic approach in practice.

System-differentiating and system-integrating approaches are two different, strategies and activities of the system, which are caused by qualitatively different

processes. Currently, innovation in organization and management requires not just a systematic approach, it require a system-integrating approach.

The essence of the system-differentiating approach is that the corresponding system is built on the basis of continuous differentiation in accordance with the goal. In the event that there is a preliminary tree of goals, more and more new components are gradually separated in the system. A typical example in this regard is the process of differentiation in the area of science and the complexity of its organization.

Now there are over a thousand sciences and scientific disciplines. Something similar is observed in the organization of science—scientific links (institutes, sectors, sections) of research in the area of individual sciences are created. It should be noted that at a certain stage, all these links are organized into larger systems—scientific centers, academies. The organization of science is a certain system that functions according to the laws of a system-differentiating approach.

The first type. In the process of creating a system, first of all, the system's governing bodies are isolated as a whole—without this, the system can't function.

A feature of such a system is the fact that the creation of a component at the lowest level of the vertical is usually preceded by the formation of a subsystem at other, intermediate stages. In this case, the process of integration of science and production began with the creation of separate scientific links (institutes, laboratories), which at later stages comprise scientific associations—centers.

The second type. The construction of a control system according to the laws of a system-differentiating approach is carried out by sequentially isolating the central output and input subsystems. Directly in the system, the processes proceed in the direction from the input to the central and from it to the output subsystem.

This order can change during the formation of systems, if the central subsystem is crucial, and the result appears in the name of which the system was created.

For example: the emergence of scientific organizations such as academies, research centers, where the development of the system began with the separation of the scientific link, and later created information and other bodies.

During its inception, a system-differentiating approach was a fundamentally new idea in the theory and practice of management. It influenced the construction of systems, especially control systems, which are based on certain principles and goals, capable of solving extremely complex and difficult tasks. Using a system-differentiating approach, the diversity (in the cybernetic sense) of the control subject was achieved, which decisively contributed to the reduction of the variety of control objects to rational limits.

The dialectic of the development of the system approach area is that at a certain stage the system-differentiating approach inevitably begins to exhaust its capabilities. Theorists and practitioners have noted serious shortcomings of this approach for decades, that couldn't contradict the ever-growing integration processes between different sectors, sub-sectors and activities.

In general, the deepening of differentiation in this system has its limits—differentiation is useful as long as the necessary diversity of the system is provided. There may come a moment when the system faces a kind of destruction.

In this case, it's necessary to take measures to prevent a decrease in the effectiveness of the system [11].

With a system-differentiating approach, the situation is very different—activities and resources are components of the corresponding systems, and their coordination and unity in the implementation of the goal is carried out through traditional coordination.

The methodology of the system-integrating approach assumes that the integration of the first kind on a systemic basis requires a correspondingly integrated management body. This introduces some new points in the organization of systems.

According to some experts, a system-integrating approach requires serious changes in the management structure. It seriously undermines confidence in traditional functional specialization and in a strictly vertical hierarchical organizational structure. Instead of models of a stable organization, a system-integrating approach ensures the using of a model of a changing organization, which is adapted to function in a dynamic environment. In accordance with this, a system-integrating approach has led to new requirements for the qualities of a leader and employees.

3 Results

Following the global trends, there is widespread digitalization of management of various economic entities, respectively; the transition to the automation of business processes becomes the main lever for gaining a competitive advantage in the market.

A methodological study of various vectors of application of systemic approaches, which are analyzed in this article, confirms the importance of applying these principles in organizing the activities of companies in modern conditions, as it helps to build an integrated management system at different levels of the enterprise.

The introduction of a systematic approach when reviewing the design activities of an organization, which is a complex and diverse activity, is especially relevant. At the same time, the formation or transformation of project management in a company, depending on the stage of implementation of such a corporate system, is based on both system-integrating and system-differentiating approaches.

Building a corporate project management system in an organization for various areas of activity becomes a necessary step in the development of a project-oriented enterprise, especially in the context of digital business transformation [12].

Based on the name, it's obvious that the corporate project management system is based on a holistic principle that takes into account the whole range of interconnections of the human resources of the company and the material and technical means, which are necessary for the implementation of projects.

In this connection, a system-integrating approach and a system-differentiating approach are taken into account while a corporate management system is being developed [13].

In this work, the authors investigated the relationship between the stages of implementing a corporate project management system and applying a systematic approach

to them, distinguishing between differentiating and integrating models, which can increase digital literacy in the field of project management.

From the point of view of the authors, at the first stage of developing a corporate project management system, the activities of a project-oriented organization should be analyzed and the directions, which should be carried out according to the project principle, should be classified. The standardization of project management should be carried out by differentiating projects into classes, types, prospects, scale and complexity of projects.

The next step is to identify and unify the business processes required for the implementation of classified projects, it's important to use a system-integrated approach for this that will reveal the patterns of project execution.

Therefore, it is important to compile a library of projects implemented in the organization, and in this regard, the third stage is the selection and using of technological means of information processing, which allow a comprehensive assessment of the processes and results of project activities.

At the same time, the digitalization of the stages of project management allows you to build an effective business analytics of the stages of implementation of the organization's projects, which makes it possible to intensify research in the area of project management.

At the same time, the capabilities of business metrics analytics make it possible to evaluate individual projects according to a differentiating feature and in a synchronized form according to the classification of projects, based on integration features, which allows a comprehensive assessment of the results and reveals the patterns inherent in each type of project [9].

The final stage in the development of a corporate management system is the definition of the organizational structure of project management. It should be noted, that the application of the integrating approach in this case is inherent in organizations, which carrying out project activities through the project office or project committee [14]. The differentiating approach is used in organizations with a functional or matrix organizational structure, where project management is carried out by individual units [15].

Based on the all of the text above, it's possible to distinguish the main advantages of applying a systematic approach to the organization of project management, the main purpose of which is the possibility of developing a continuous digitalization strategy for project management and the ability to avoid isolated definitions and formulate individual terms and their definitions within the framework of an agreed terminological system [16].

From the position of the principle of systemic research of the indicated problem, the starting points of which were the ideas about:

- the integrity of the system of continuous digitalization of management in all the diversity of its institutional, non-institutional components;
- differentiation of the components of the system of continuous digitalization of control as elements, whose properties and functions are determined by their essence within the framework of the whole system;

- the integrity of the system through the concept of "communication", which are system-forming;
- a set of relationships (the "forms" considered by us) and their characteristic properties, leading to the integrity of the structure and organization of the process of continuous digitalization of project management.

4 Conclusion

Nowadays, new methods of system research and also specialized methods and procedures, which allow you to apply a systematic approach in digitalization, have been developed. Progress in this area is largely due to advances in the digitalization of project management. It's premature to argue that the systems approach is a holistic theory with relevant laws, procedures, techniques and research methods [17]. Currently, there is still a process of final determination of the face and specifics of this approach. But now it's completely clear that the success of the further development of the systems approach depends on how deeply and organically it will be based on the dialectical materialist theory as a scientific philosophical methodology.

We also can add to the all of this that in our time, dozens of scientific disciplines are related to system analysis with the help of which such concepts as "whole", "element", "connection", "structure" are formulated. Models and concepts are optimized at lower levels of the hierarchical structure [18].

At the present time, there is a deep process of further development and enrichment with ideas of integration and synthesis in the theory of systems. The transition from a system-differentiating to a system-integrating approach is so briefly possible to express the most important process in the considered area.

Features of Restaurant Business Management in a Competitive Environment

Marianna S. Santalova, Irina V. Soklakova, Dariko K. Balakhanova, Elena Yu. Kuzmina, and Olga G. Charykova

Abstract *The purpose* of the work is to evaluate the management system of specific restaurants and develop a system of quality training of staff. *Design methodology approach*: In this work, the authors rely on comparison methods, principles of comparative and competitive analysis, criteria for evaluating the effectiveness of the restaurant business; the points of view of such theorists and practitioners as Aleschenko V. V., Aminov E. F., Baumgarter L. V., Santalova M. S. and others. *Findings*: The article identifies the strengths and weaknesses of the main competitors in the restaurant business, a comparative analysis of the competitive positions of restaurants, an assessment of the effectiveness of catering, the criterion of the effectiveness of their activities, the competitiveness of restaurant services. It is concluded that non-price methods of competition are of particular importance, since the restaurant service is not only food, but also the service of the process of taking food with the provision of a range of additional services. *Originality value*: The organization of the training system in the restaurant as a non-price method of competition is proposed. The training system of a new employee may include the following stages:

1 Introduction

Such a category as competitiveness, until recently, was a little developed domestic economic science, but now it has acquired great importance and relevance in a market economy.

Today, enterprises and organizations are increasingly feeling the strengthening of competition, they increasingly have to think about their own competitive position and gain absolute advantages in the market. Economic success (and often survival) of the subject of market economy, first of all depends on how well it knows the laws of competition, its manifestations and forms and how ready for competition. The study of competition is one of the most important components of market research, creating the basis for the development of strategies and tactics in the market, choosing the right way to improve the technical level and quality, which is the basis of competitiveness management in the enterprise. Assessment of the market situation, analysis of the impact of forces and environmental factors, determining its further development is important in the development of the company's strategy.

Assessment of the restaurant business and analysis of the competitive environment of the restaurant is relevant and requires constant analysis in order to modernize. That is why modern restaurants are interested in updating the management system and searching for the specifics of their activities.

2 Methodology

Methods of managing the competitiveness of the restaurant business are studied and applied for a long period. Many scientists-theorists and practitioners develop the principles of restaurant business management, methods for evaluating its effectiveness, and suggest ways to modernize it, taking into account the training of staff.

The competitiveness of the restaurant business and updated issues of personnel management and its evaluation are actively studied Aminov [1], Aleschenko [2], Baumgarter [3], Santalova [4–7], Petrov [7], Kuskova [8], Kaplina [9], Azoev [10],

Dmitrieva [11], Zerbaliyeva [12], Didenko [13], Lesnikova [14], Turkov [15] and others, which the authors rely on in their research.

3 Results

In order to study the competitive features of the restaurant business, consider the competitive position of the restaurant 1. The main competitors of restaurant 1 are "restaurant 2" and "restaurant 3". The strengths and weaknesses of competitors will be presented in Table 1.

A comparative analysis of the competitive positions of the object of study and its main competitors will be presented in Table 2.

We will assess the performance of management of catering, which is reflected in Table 3.

Taking the data on the efficiency of enterprises-competitors, we will further assess the effectiveness of the "Restaurant 1". In this case, the assessment will be made in points (5, 10 and 15). The value of indicator 5 indicates that this indicator is the lowest among the analyzed companies, 5—the average, 15—the highest. The results will be presented in Table 4.

Table 1 Strengths and weaknesses of the main competitors

Competitor	Strength	Weakness
Restaurant 3	Powerful production base Own financial institutions Aggressive advertising policy System of discounts and bonuses Constant growth and access to the regions	Position only the trademark, confusing it with the brand, the brand of the company does not pay enough attention Some underestimation of competitors
Restaurant 2	Own production base Powerful administrative resource	The main volumes of services in the city Forced to focus on the load of their production capacity

Table 2 Comparative analysis of competitive positions

Success factor	Weight (%)	Restaurant 1 (%)	Restaurant 3 (%)	Restaurant 2 (%)
Powerful production base	20	14	20	17
Quality of services	30	23	28	27
Effective management	10	7	8	7
Financial resources	30	30	30	27
Brand awareness	10	8	7	5
Competitive position	100	82	93	83

Table 3 Evaluation of the efficiency of public catering enterprises

Criteria and indicators of competitiveness	Indicator calculation rule
1. Expenses on the received revenue, RUB	Gross cost/Revenue
2. Return on assets thousand rubles	Revenue/average annual value of fixed assets
3. Profitability of services,%	Profit from sales * 100%/company costs
4. Labor productivity, million rubles/person	Revenue/average number of employees

Table 4 Evaluation of the effectiveness of competing enterprises (in points)

Criteria and indicators of competitiveness of the first group	Average value	Points		
		Restaurant 2	Restaurant 3	Restaurant 1
1. The costs of the proceeds	0.8675	15	10	5
2. Fund return	0.825	5	15	5
3. Profitability	14.25	10	15	5
4. Labor productivity	263	5	15	10

The data of Table 4 do not allow to visually determine the clear leader in terms of the efficiency of companies. There is a fairly wide variation in the values of the estimates in points.

Therefore, we define the criterion of the effectiveness of the activities of each enterprise by the formula:

$$\mathrm{EP} = 0.31\mathrm{I} + 0.19\mathrm{F} + 0.40\mathrm{RT} + 0.10\mathrm{P} \tag{1}$$

where

I—a relative indicator of the costs of the company's revenue;
F—relative indicator of capital productivity;
RT is a relative indicator of profitability of services;
P is a relative indicator of labor productivity;
0.31; 0.19; 0.40; 0.10—weighting factors indicators.

$$\mathrm{EP(Restaurant\,2)} = 0.31 * 15 + 0.19 * 5 + 0.40 * 10 + 0.10 * 5 = 10.1$$
$$\mathrm{EP(Restaurant\,3)} = 0.31 * 10 + 0.19 * 15 + 0.40 * 15 + 0.10 * 15 = 13.45$$
$$\mathrm{EP(Restaurant\,1)} = 0.31 * 5 + 0.19 * 5 + 0.40 * 5 + 0.10 * 10 = 5.5$$

Thus, we find that according to the evaluation of the activity, the best indicator for the company "Restaurant 3", the worst one in the Restaurant 1.

Moreover, it should be noted that this indicator in Restaurant 1 is 2 times less and 2.5 times less than that of Restaurant 2 and Restaurant 3, respectively. From this we can conclude about the urgent need to improve the efficiency of the restaurant 1.

Table 5 Assessment of the competitiveness of services

Criteria and indicators of competitiveness of the third group	Points		
	Restaurant 2	Restaurant 1	Restaurant 3
1. Price of services	15	10	15
2. Efficiency of the company's employees	15	5	10
3. Company reputation	5	15	10
4. Assortment	5	15	15

We will assess the competitiveness of the services of the competing enterprises under consideration on the basis of analytical materials, immediately putting points on enterprises, evaluating the quality and cost of their services (Table 5).

Next, we determine the coefficient of competitiveness of restaurant services according to the formula

$$CC = 0.25 * C + 0.4 * O + 0.2 * R + 0.15 * A \quad (2)$$

where

C—the price of services;
O—Efficiency of work of the company's employees;
R—Company Reputation;
A—Assortment.

$$CC(\text{Restaurant } 2) = 0.25 * 15 + 0.4 * 15 + 0.2 * 5 + 0.15 * 5 = 11.5$$
$$CC(\text{Restaurant } 1) = 0.25 * 10 + 0.4 * 5 + 0.2 * 15 + 0.15 * 15 = 9.75$$
$$CC(\text{Restaurant } 3) = 0.25 * 15 + 0.4 * 10 + 0.2 * 10 + 0.15 * 15 = 12$$

After analyzing the data on the competitiveness of services, we find that, according to the competitiveness assessment, the palm is in Restaurant 2, the worst indicator in restaurant 1.

The problems of restaurant 1 are mainly related to the staff. Ordinary employees need the most attention from the managerial staff, because they bring revenues to the institution—waiters, bartenders, cooks, hostesses, cashiers, etc. Unfortunately, in most restaurants and cafes these employees are treated as temporary staff—they came, worked, left, so high turnover reduces the motivation of working with staff to almost zero.

It turns out a vicious circle. Managers and directors of restaurants and cafes are not engaged in staff training and development due to high turnover: "Why train and develop if he/she goes to competitors tomorrow?" But what's worse: if you trained your employees and they left you, or if you do not train them, and they work and do not leave? Consider the organization of the training system in a restaurant with a

specific example. The training system for a new employee may include the following steps:

(1) familiarity with the restaurant;
(2) post skills training;
(3) certification.

Personnel management dictionary. An intern is a person who has entered a new job and is undergoing a probationary period during which his abilities are evaluated and work experience is acquired in his specialty.

The task of the manager is to create such a procedure of acquaintance, which will allow the employee to find out as much information as possible about the new place of work, but at the same time will not take a lot of time from the manager or other employees of the restaurant.

For this you can use several tools.

1. Sheet of the first day—it lists all the procedures that the manager and the new employee need to perform on the first day at work (Fig. 1).

The sheet of the first day is drawn up by the manager, who communicates with the employee who came to the restaurant on his first working day. First of all, the manager should conduct a tour of the restaurant for the intern. During the tour, the manager tells the novice how all the departments of the restaurant work and what they are for. Issues uniform, tutorials, training schedule, record book; gets a file of all necessary forms and documents to the employee; gives the keys to the drawer in the locker room of employees; prepares all necessary documents for admission to work (application for admission to work, medical book, employment record book, etc., depending on the competence of the manager); draws up an employee's pass,

First day sheet

- Take a tour of the restaurant.
- To issue a uniform.
- To issue tutorials.
- To issue a training schedule, observation sheets and record book.
- Check out the employee's folder.
- To give the box in the locker room.
- Issue documents for admission to work.
- Issue employee badge.
- Attach to the mentor (coach)

Fig. 1 Sheet of the first day

with which the employee will be able to mark the time of arrival and departure from work. It also attaches to a trainer-mentor (an experienced employee who has completed training courses for trainers-mentors) for training.

At the next meeting of the shift, the manager should introduce all the employees to the new intern and ask for the newcomer to provide all necessary assistance.

2. Tutorials. The manual on the post of the employee at the first stage is necessary to obtain information.

Schedule employee training. Schedule includes a list of topics that the employee must study on their own (if relevant training materials are available). The schedule includes a description of each employee's training day, a topic for study, a place in the workbook where he can learn about this topic in more detail, a control method—what tests he needs to pass. The schedule also includes notes about the practical activity of the trainee—work on working out the necessary skills under the supervision of a trainer-mentor (Table 6).

3. Sheets of observation. They are a list of questions that the intern (employee of the hall) must answer, observing the work of this or that department. Thus, having answered all the questions on this form, the intern will have an idea of what the work of the staff in this area of the institution is. The forms of the sheets are presented in two versions—"Observation" and "Fulfillment of duties" (Table 7).

The first introduces, the second provides an opportunity to understand how this department operates. In each form, put a mark coach and mentor manager. The trainee is given 2 h to complete and complete each form. Forms are created for all existing departments of the restaurant (hostess, hall, bar, kitchen). When passing the form "Observation" or "Fulfillment of Responsibilities", a mentor of the department with which the trainee becomes acquainted is attached to the intern. For example, during the passage of the form "Monitoring the work of the waiter," the manager responsible for training the trainee selects a mentor from among the working waiters and introduces him to the trainee. The trainee should not distract the waiter from work, but if he has any questions, he should get answers from him. The same applies to the passage of the "Fulfillment of Responsibilities" form, with the only difference that the trainee himself performs the duties of the staff of one or another department.

4. Record. In the record book, the trainer can mark the delivery of tests by the trainee on the menu, tests on work standards, rate guest service, etc. qualification tests (Table 8).

To study the standards, it makes sense to create training manuals that would include all the information relating to the work of this department.

Clearly written manuals will help save time—the beginner will find the answers to all his questions, and if it is not clear, he will turn to the mentor (coach). With this approach, there is not only a reduction in the cost of teachers' salaries, but also an individual approach to training interns and better training of new employees, since all knowledge is stored in one document. Allowances should be created for all

Table 6 Sample bartenders training plan

Change	Key topics/homework	Location in the textbook	Control and supervision	Tests
1	2	3	4	5
1	– A tour of the restaurant – Credo, the mission of the company – "Who is who" in the restaurant. – How will be trained? – Distribution of textbooks and uniforms – Coming and leaving work – Safety rules, uniform standards – Terms and abbreviations – Teamwork – Numbering of tables – Bar menu and main – review Homework: – Learn the numbering of the tables – Learn the food menu – Learn the drinks menu	Chapter 1 Chapter 1 Chapter 1 Chapter 1 Chapter 1 Chapter 1 Chapter 1 Applications: Seminar: "Teamwork"	Checklist familiarization: – Assistant waiter – Host/hostess On-the-job training checklist: – Assistant waiter – Host/hostess

departments (waiters, hostesses, cooks, etc.). Figure 2 presents an exemplary list of topics for bartenders manual.

Example The sections of the training manual on the menu: the menu of dishes; dessert card; cocktail card; strong alcohol menu; wine map; soft and low alcohol drinks; additional.

Sections of the study guide on cocktails: a variety of cocktails; the name of the cocktail; a photo; Ingredients; decoration; dishes; cooking method; taste characteristics and strength (for example: female, light, fruity).

For cooks, in addition to teaching aids on sanitation and kitchen work standards, recipe books for cooking are also created. According to him, the cooks are in the process of learning and subsequently prepare meals at the stations of the kitchen.

4 Conclusion

The result of the introduction of these events was the emergence of restaurant 1 among the leaders in the restaurant business market. The proposed system of training of restaurant staff has shown its effectiveness and has provided an increase in the competitiveness of the restaurant 1.

Approximate list of topics for training bartenders

Introduction

Chapter 1. Orientation (history, principles and mission of the company, a tour of the restaurant, the role and tasks of the bartender, the uniform of the bartender, etc.).

Chapter 2. Telephone etiquette (how to answer calls, calls for guests, for managers, for employees).

Chapter 3. Sanitation hall (food handling, personal hygiene, storage of hot and cold dishes, cleaning the restaurant, etc.).

Chapter 4. Equipment (the main stations of the bar, the use of bar equipment, bar utensils, the rules for handling dishes).

Chapter 5. Bar operation (opening a bar, bartender duties during the day, leaving work and closing the bar).

Chapter 6. Guest services (service standards, basic service rules, conflict resolution, etc.).

Chapter 7. The principles of turnover in the bar (inventory, order for a warehouse).

Chapter 8. Technique of order fulfillment (supply of beer, wine, hot drinks, preparation of alcoholic and non-alcoholic beverages, the appearance of the drink, etc.).

Applications.

Appendix 1. Training schedule.

Appendix 2. Control forms.

Appendix 3. Forms of observation.

Appendix 4. Certification bartender.

Appendix 5. Test on the menu.

Appendix 6. Feedback sheet.

Attachment 7. Drink test.

Appendix 8. The final test bartender

Fig. 2 A sample list of topics for bartenders

Acknowledgements The proposed measures were introduced into the practice of restaurant 1 and were discussed in the process of holding round tables of the Management department of the Moscow Economic Institute and in the restaurant 1.

Analysis of the Architecture-Creation Methodology of Integrated Management Systems in the Context of Economic Digitalization

Yuliya I. Ryzhova

Abstract This article is devoted to a detailed analysis and challenges of SIS-class systems design. The author showed the necessity of developing the theoretical foundations of ontological design, as well as a methodology of building conceptual, logical, and hierarchical models of management architectures, reference data classification systems, as well as delivery forms and mechanisms of semantic topology. The author stresses the importance of semantic data processing and semantic communications in global networks within a digitalized economy.

Keywords Information technology · Semantic topology · Metalanguage · Corporate management · Economic digitalization

JEL Classification I25 · N3 · 015 · 032

1 Introduction

The growing number of areas and scope of the application of information technologies in public and corporate management has exhibited in the development of special-class systems "Software Intensive Systems (SIS)". The feature set of such systems is substantially determined by software.

2 Background Information and Methodology

The system for management of socio-economic development in the context of economic digitalization is distinguished by a variety of interconnected subject domains, large volumes and high speed of information flows, the considerable scale of software. Due to its complex nature and the need for advanced tools of analytical

E. G. Popkova et al. (eds.), *Socio-economic Systems: Paradigms for the Future*,
Studies in Systems, Decision and Control 314,
https://doi.org/10.1007/978-3-030-56433-9_103

data processing, such a system is referred to as SIS-class. It follows that the problem statement and solution of problems on control system development is contingent on the approaches and the general methodology of SIS creation.

The key prerequisite for the development of SIS is the validity and sophistication of its architecture, which provides the required understanding between the participants of the system. Conceptual and logical models of architecture act as a basis for a common outlook of the problems to be solved, as well as the criterion for consistency between the components and stages of the system development and the goals of its development and application.

Social networks and cloud computing translating into the corporate management field general problems of the global information space such as Big Data and Semantic Interoperability are new factors determining the problem scope and design of SIS. These problems are largely associated with the semantic considerations of the ontological provision of management. Numerous applications of conventional linguistic, formal-logic, and statistical methods for the analysis of information communications to solve the above problems do not bring the expected results, which necessitates the development of the theoretical foundations of ontological design, as well as the methodology for building conceptual, logical and hierarchical models of control architectures, reference data classification systems (hereinafter—NSI) and arrangement of information processes.

It becomes obvious that for adequate representation of the subject domain items and fitting of information systems (hereinafter—IS) with tools for effective search and analytical processing of information documents and database architectures should be standardized and their forms should be aligned with the semantic content of the activity. The stated problems are understudied, and information processes are ill-prepared for the effective use of information technologies (hereinafter—IT) in the field of complex systems management.

It is advisable to lay the findings of research by Intelteq company forming the methodological complex "semantic topology" as a foundation of problem-solving. This complex integrates, under a certain principle, the knowledge of philosophy, mathematics, psychology, sociology, semantics, and computer science into a holistic approach that allows us to constructively pose and solve complex problems of meaning-making and comprehension in information communication of contact groups. This methodology enabling the organization of discursive thinking under strict rules with the semantic design of complex human systems, as well as a uniform comprehension of the texts. This is necessary for a qualitative ontological study of the SIS architecture in terms of providing the holistic representation of interconnected subject domains and the reducibility of their classifiers due to the invariance of conceptual and logical models.

A historical analysis of the origin and evolvement of the idea of semantic reality modeling stems from the treatises of the Spanish monk and philosopher R. Lullius (XIII–XIV centuries). His logical machine Ars Magna is a world description scheme using elements of a finite and ordered set of truths collected in a nine-point matrix. From this alphabet of meanings, all conceptualized worldviews are assumed to be

derived under certain rules by establishing a community of its original truths with specific objects of the substantive world.

The compilation and existence of the "alphabet of human thoughts" were admitted by R. Descartes,[1] G. Leibniz,[2] B. Pascal,[3] V. Pauli,[4] and G. Jung.[5] They associated thinking with the "collective unconscious" that is based on "archetypes" as the general premises of semantic communication in all languages and knowledge systems. Similar ideas are being developed today by A. Verzhbitskaya (the concept of "semantic primitives")[6] and Yu. Apresyan ("quantum semantic elements").[7]

An important role in semantic topology is attached to the definition of "*meaning*" as a substantial connection between the worlds of the physical and mental in the triad "consciousness—meaning—matter". Such an approach is similar to V. Nalimov's concept[8]: meaning is what the texts are created from using the language; texts are that is made of meanings with the help of language; language is a means by which texts are born from meanings. Within this approach, thinking is interpreted as rendering and conveying the meanings of reality in accordance with the laws of the space existence and development in the internal dialogue of a person as a two-in-one entity: "homo sapiens" and "dimensional man" (R. Descartes).[9]

The good reasons for meanings and semantic unity of modern physical, biological, and socio-psychological theories are bound with the laws of space architecture and existence. Such a worldview is based on the definition of life by E. Schrodinger as the ordered behavior of matter,[10] as well as an explanation by A. Gurvich of living systems as a predetermined position of elements in the coordinate system of the whole organism and the interpretation of the biological order as reasonable subordination of elements as opposed to their simple "interaction".[11]

This allowed defining meaning-making and meaning-comprehending as an expression of the stable predetermination of the world by physical constants, the ordered behavior of living systems, and the symbolic elucidation of the natural connection of mankind with the matter-energy structure of reality. The need for a spatial conception of thinking is also associated with a new paradigm of physical reality where the space-time geometry and information flow are not two opposite entities, but different representations of the world as one network evolving over time.

Currently, the concentration of efforts on the technical considerations of IS with poor attention to their cognitive foundations has resulted in multiple problems of semantic character. Numerous applications of conventional linguistic, formal-logic, and statistical methods for the analysis of information communications to solve the above problems do not bring the expected results. This situation necessitates the development of the theoretical foundations of ontological design, as well as the methodology for building conceptual, logical, and hierarchical models of control architectures, reference data classification systems, and arrangement of information processes. It becomes obvious that for adequate representation of the subject domain items and fitting of information systems with tools for effective search and analytical processing of information, documents and database architectures should be standardized and their forms should be aligned with the semantic content of the activity.

The stated problems are understudied, and information processes are ill-prepared for the effective use of information technologies (hereinafter—IT) in the field of complex systems management. The research findings and developments in this scientific field are presented as new ideas, techniques, and tools that make up a theoretical complex provisionally titled "semantic topology", which is based on the interpretation of the collective mind of mankind as a global deductive system built on different principles than individual thinking. Its theoretical foundation is universal knowledge, concentrated in classical philosophy and mathematics. This approach develops the provision stated by artificial intelligence scientist M. Minsky that the semantic framework of the reality representation cannot be created beyond the global scheme of knowledge organization.

3 Discussions and Research Findings

The representation of the world as a holistic unity of structure and information requires the development of a metalanguage for which the meaning is an ontological rather than a logical category. Its key point is the ability to represent a holistic multidimensional-cyclic world landscape as a network of semantic elements. This distinguishes the metalanguage from the common language premised on a discrete-linear principle and points at the futility of solving the semantic communication problems by linguistic means.

The stated approach is relied on the studies by Yu. Lotman, who believed that a metalanguage was an essential condition for a "collective mind" operation. In the concept of Yu. Lotman, the metalanguage is defined as a "central text-forming device" confining its diversity to invariant images, establishing the unity between the phenomena, playing a classification and ordering role in the texts of the natural language, and arranging the collective thinking of contact groups.[12]

[12] See: [13].

The mathematical apparatus of space description is topology, which provides a holistic representation of objects and the consideration of any parts of them in the context of the whole and inextricable linkage with it. Group-theoretical understanding and topological representation of the semantic element system stands out the presented development from other conceptual models. In this connection, it is appropriate to turn attention to the methodological incorrectness of attempts to reveal a finite set of semantic elements outside certain mathematical groups. Only a group-theoretical approach allows identifying the criteria for the selection of semantic elements, working out the rules for their coordination and strict arrangement in the semantic topological space.

The principle of symmetry as the main idea of the world order and feasible mathematical representation was the chosen foundation of the topological organization of semantic element space. This circumstance much differs the described approach from other works on the development of information system ontologies, where the form of integrity and building strategy are generally not determined. As a rule, the proposed ontological systems are the outcome of observational generalizations and agreements between some groups of participants in information exchange. The analysis carried out in this area indicates the unavailability of research and developments using a group-theoretical approach to integrity determination and the principle of symmetry as the basis for connecting parts into integrity.

An instrumental solution to such a problem can be applied as follows. Mathematical groups in space may be represented by polyhedra. The correlation of semantic groups with polyhedra and their combinations is natural and explainable. Exactly the geometry acts as a tool for a visual representation of the surrounding space and mutual understanding between participants in information communications regardless of the language of communication. This explains the instinctive tendency of man towards the interpretation of his sensations in the spirit of Euclidean geometry. The structuring of semantic element space using mathematical groups of polyhedra also meets the current trend of "geometricization" of thinking in contemporary natural science theories.

An important place in justification of the approach and modeling of semantic communications is a division of geometric bodies into different mathematical groups such as irrational icosahedral groups (quasicrystals with the living properties and the ability to disengage from the environment and exist autonomously); rational three-dimensional spaces [crystallographic groups providing the undistorted translation of the unit cell in various directions (cubic complexes)]. These properties of space allowed simulating the mechanism of information exchange between participants in semantic communications as entities interacting in isotropic three-dimensional space. Let's represent this mechanism as the composition of the icosahedron, which vertices connect it by hexahedrons to surrounding formed by other icosahedrons (cubes) (Fig. 1).

The composed model is a polyhedron with 52 vertices and 100 edges with different topological statuses such as 4 corner vertices, 12 nuclear and 36 nodal vertices; 4 central, 24 system-forming, and 72 defining edges. Semantic elements are defined in the space of a natural language by the criteria for their conformance to the group

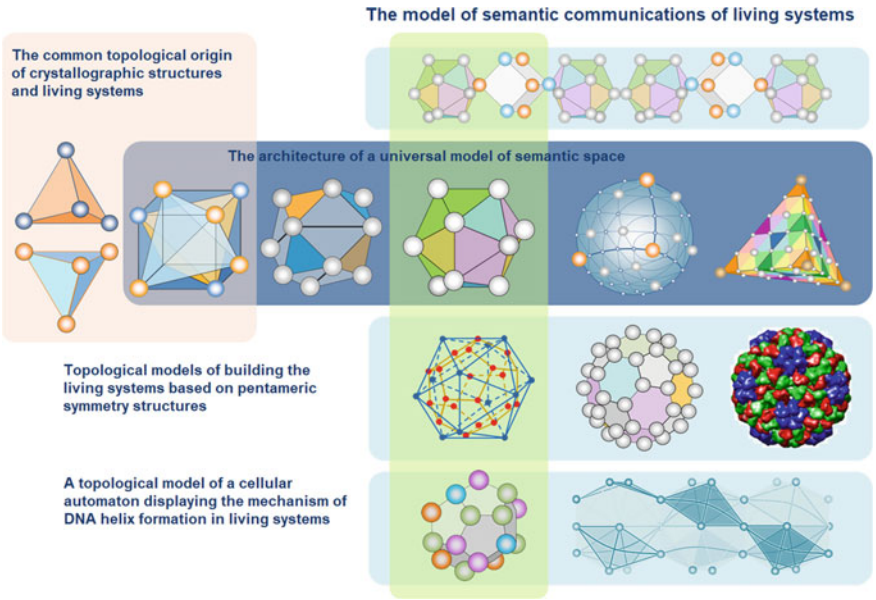

Fig. 1 Composing a model of semantic space

properties of geometric models and capacity for generation of semantic sets within such mathematical groups (Fig. 2).

The studies show a wide consensus among the scientific community regarding a common basis of the quantum world and consciousness. Comparability of the subconsciousness idea with the notion of "field" in physics allows talking about a single psychophysical reality structured by meanings. The discovery by K. Jung and W. Pauli of the unity of physical and mental phenomena brought archetypes to the foundation of collective thinking up to its universalization and structural coincidence with physical reality such as carbon structure.

The provisions of Jung's theory on the archetypal nature of the subconsciousness expressed in the collective unconscious were applied to distinguish semantic elements from many concepts of a natural language. It is related to the high socio-psychological status of archetypal images having a pre-scientific origin and exhibiting the direct linkage of the subconscious with physical reality. Archetypes constitute the ontological basis of mutual understanding between peoples, sciences, and practices and play a role of objectively existing meanings and pre-text messages about the world. And the text acts as a "technical package" for the delivery of meanings in social communications. The archetype concepts are chosen from the natural language corpus following the regularities of shaped topological space and subject to the conditions of their ontological consistency. The semantic elements selected under this principle are similar to physical entities, which are manifested in physical invariants (conservation laws). Stable links between archetype concepts are similarly represented as semantic invariants and recording of world order laws reflection in our consciousness.

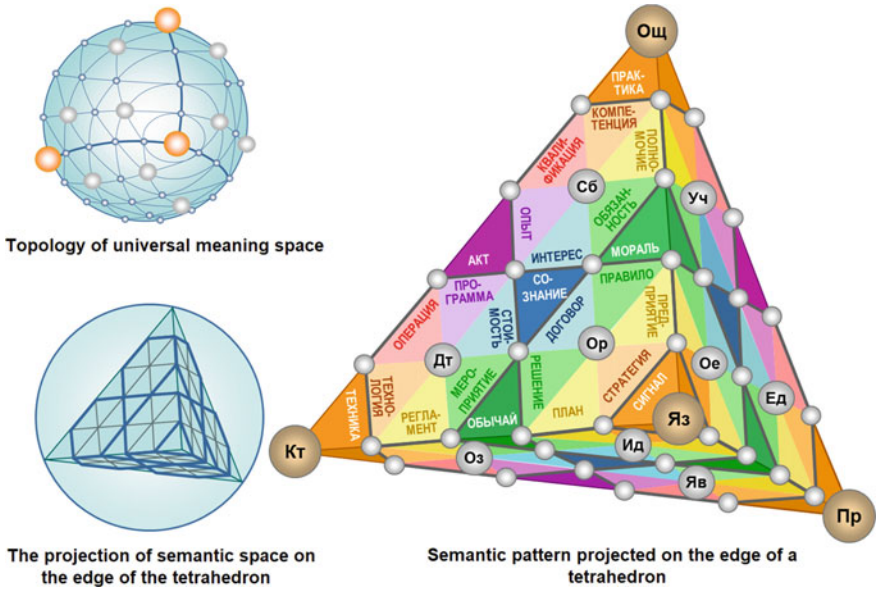

Fig. 2 General representation and structuring of the topological space of semantic elements

Individual consciousness existing in the space of a common language and the subconsciousness (collective unconscious) footed on archetypes are correlated as complementary opposites. For this reason, the methodological complex of meaning-making and comprehension can be built on the communication of two languages: a discrete linear language of domain description of some world phenomena and a multidimensional cyclic metalanguage displaying the holistic view of the world.

A metalanguage made up of archetypal concepts does not claim to replace the common language but provides the performance of its main function—appropriate conveyance of the message sense. The relatively autonomous existence of meaning in relation to the text assigns to the metalanguage the role to directly express the meanings and be a perfect tool of semantic communication. The metalanguage is composed though identifying and recording the moments of self-organization of displayed entities in the concepts-archetypes relationships as a result of their local interaction (autopoiesis). This approach meets the requirements of synergetics and its helpful application for setting and solving semantic problems of information communications.

The logic of meaning-making delivered with the help of metalanguage is the compilation of certain combinations of concepts-archetypes in the arranged topological space. Comprehension is attained by establishing the relationship of semantic text fragments with certain semantic elements. Keeping the invariant of semantic element relationships for any of their specific values is crucial in the logic of meaning-making and comprehension.

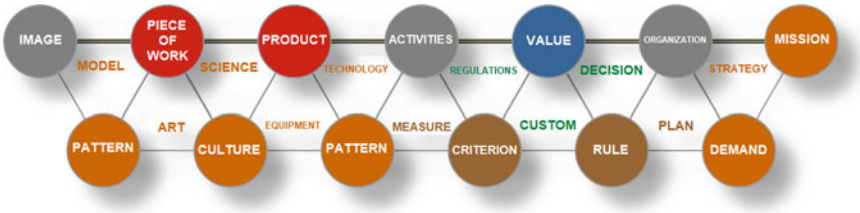

Fig. 3 A fragment of the conceptual model of semantic topology as a space for strategies development

The basis of semantic topology is the matrix of meanings presenting a three-dimensional network structure within which semantic concepts are defined by their position in the network and surrounding. This matrix fixes the invariant of meanings under any specific value.

The "grammar" of the semantic topology language is symmetry, static (reflection, rotation, sliding) and dynamic (cycles, spirals, returns).

The model can be verified by comparison with the logic of "common sense", philosophical knowledge categories, conventional theoretical ideas in the corresponding segments of the "matrix of meanings". The management strategies of complex systems are developed through selecting and comparing the motion paths from the initial to the given point in the semantic network (Fig. 3).

The "Matrix of Meanings" is easily algorithmized, programmed and visualized, which provides a linkage between management and IT. Semantic technology tools enable the development of a range of IT products for management smartness.

Determination of finite set of metalanguage elements and invariants of their relations, as well as the rules of meaning-making and comprehension of texts in the topological space of semantic elements, can be taken as a theoretical basis for a new transdisciplinary area (semantic calculus). The latter allows setting and solving problems of semantic design of complex activities and semantic interpretation of situations, as well as the linkage of text with context under the rules of a holistic view of reality within the developed topological space. The semantic content of concepts-archetypes that make up this space is expressed through the specification of their semantic surrounding. The topological definition of semantic concepts largely coincides with their theoretical definitions in scientific knowledge corpora. The proof of the correlation between semantic groups of concepts-archetypes and figures of speech, which naturally engrained in a common language, is of great importance for verification of the results obtained.

The form of reality representation topologically organized in the metalanguage reproduces the law of the network composition of the world and its regularity that are based on spatio-temporal symmetry. This model surmounts anti-network thinking, helps to recognize the semantic content of texts, and performs semantic design. In semantic calculus, the grammar of a common language is replaced by strict mathematical rules of building semantic sets by semantic similarity, coherence, interreflection, and other group properties.

Besides, "semantic topology" does not impose tough decisions, but builds discursive thinking when solving the meaning-making problems in complex systems and facilitating comprehension in information communications.

The first applications of the "semantic topology" for the solution of corporate management problems, development of ontological models of database activity, and structuring indicate its constructiveness and broad opportunities for bridging the gaps between the intellectual-semantic and formal-technological nuances of building management architectures for large complex systems. The metalanguage of "semantic topology" allows developing conceptual and logical models for the management of strategy delivery at different hierarchical levels using a common set of concepts and logical interconnections. This makes possible the vertical assembly of the parameters of control objects through their specification and generalization while the general semantic structure remains unchanged.

The conceptual and logical models of "semantic topology" were applied in the development of a methodology for calculation and submission of a balanced scorecard (hereinafter—SPP) of work of the RF Chamber of Commerce and Industry (CCI) system. An analysis of the materials uncovered a managerial problem, i.e. shift towards the principles of strategic management exposed gaps between memoranda of strategy and delivery practices. The origin of these gaps is deeply-rooted in the ontological foundations of strategic planning and the absence of smart tools to transform a conceptual description of strategic level into the semantic frameworks of instructions expressed in the domain actions language. In this regard, SPP was developed like solving the problem of strategy transforming into a description of specific actions, the result of which is attained by setting and monitoring particular indicators. SPP was built as a constructive language for spreading the strategy influence on the company's employees, informing them about the meanings of joint actions, guidelines and technologies for current and future success, and channeling collective energy into long-term goals.

Particular importance in the development of SPP is attached to the semantic considerations since SPP is foremost the language of meaningful communication between top management and executors of the company's strategy, which translates complex and blurred concepts into a more accurate form. The constructive nature of translating the general concepts of strategic intent helps the company's management be unanimous in goal setting and coordinate efforts for their achievement.

Understanding the importance of the semantic respects of strategic management did solve the problem. On the back of the conceptual model of "semantic topology," we selected a key concept of building a system for management of strategy implementation. Value served such a backbone concept. This concept is basic in theories and methods of business processes management since the accumulation and efficient use of tangible and intangible assets is at the heart of socio-economic activity. For problem-solving, we employed the conceptual models of "semantic topology", as well as the findings of logical simulation of the paths from the entity's mission towards the indicators of its practical activity (Fig. 4).

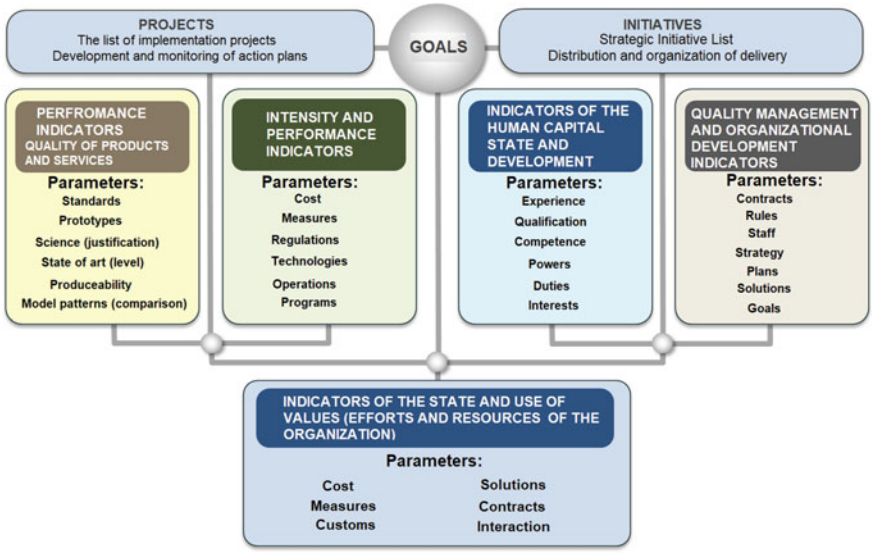

Fig. 4 The architecture of SPP for implementation of the company's strategy

4 Findings

The metalanguage of building classification systems and the interdisciplinary transfer of knowledge is demanded by the largest international businesses and scientific communities, as well as think tanks specializing in the elicitation of knowledge from the information space and analytical data processing. For the technological application of "semantic topology," it is necessary to ensure the fulfillment of conditions. The primary one is compliance with "cognitive standards" by the participants of information communications. In turn, the basis of their development is the metalanguage of "semantic topology". The cognitive standard serves a foundation and a helpful tool for high-quality ontological design, without which a sound management system architecture and a stable database framework cannot be created. Such an understanding of the content and stages of complex systems construction is in line with the global trend of shifting project activities and project management from the technological level to the ontological one. The cognitive standard provides the semantic linkage between electronic documents and common ones because in view of uniform rules for their formalization and structuring. This circumstance making an additional argument in favor of enhancing the importance and increasing the practical usefulness of the cognitive field.

The first practical applications of development in interests of some organizations have proved its high methodological potential and effective employment for solving urgent problems in the field of management and IT. The network power of societies, states, and corporations soon will be contingent rather by capabilities of semantic data processing and semantic communications in global networks than the number

of information bits. The creators of universal tools for international and interdisciplinary communications (a cognitive ISO-standardizer and an optimizer of communication environment) have high chances to take the lead in the emerging field of cognitive technologies as a theoretical foundation of information and technological development amidst ubiquitous digitalization of the economy.

Formation and Development of the Information Society: Social and Educational Dimensions of Digitization

The Social Construct of Value and Its Significance in the Development of "The Productivity Paradox of the New Digital Economy"

Evgeniya K. Karpunina, Elena A. Yurina, Maryna V. Andryiashka, Maria E. Konovalova, and Olga D. Kosorukova

Abstract In modern world of large amounts of information and digital technologies, much attention is paid to assessing the benefits and economic results of the technologies being implemented, while the social aspects of digital development are often neglected and are a source of threats to the well-being of the entire socio-economic system. One of the reasons for the productivity paradox of the new digital economy may be the inconsistency of the existing social construct of value and the vector of digital development. The purpose of the research is to reveal the productivity paradox of the digital economy and identify the socio-value reasons for its occurrence. The study of the dynamics of the current stage of socio-economic and technological development allowed the authors to identify the productivity paradox of the digital economy, which is manifested in a slowdown in labor productivity and economic growth against the background of increased investment in digital technologies and human capital development. The socio-value reasons for its occurrence are established. It is proved that in order to ensure sustainable development in the new conditions, it is necessary to integrate new phenomena of the digital environment into the traditions and values of everyday human life. This can be achieved by reviewing the role of the state in the formation of a given socio-economic orientation and behavioral attitudes in accordance with the strategy of digital development.

1 Introduction

Currently, the world community is at the stage of digital development, when not only the absolute advantages of digitalization are felt, such as GDP growth due to the development of the ICT sector and related sectors, optimization of production processes through the use of modern technologies in business strategies of enterprises (big data, Analytics, mobile technologies, private cloud, public cloud, APIs, embedded technologies [5]), growth of the non-cash transaction market (up to 41.8 billion dollars by 2021 [4]), the availability of digital technology to households in daily life, and so on.

The contradictions of digital development are becoming more obvious. They are manifested in the form of slowing economic growth, growing inequality, accelerating climate change, escalating trade and geopolitical tensions, disruptions in access to key resources, a gap in global competitiveness, declining confidence, and growing threats to information and economic security [25].

What are the causes of these contradictions? Perhaps it is because people do not understand and do not accept the changes that are taking place, because economic systems are unprepared to use them, or because regulators avoid solving the problems of ensuring human well-being when implementing policies? The study of the social aspects of digital development and the formation of a new social construct of value is becoming increasingly relevant and requires attention from modern researchers.

2 Methodology

The scientific hypothesis of the research is based on the assumption that the key contradiction of digital transformations that lead to "the productivity paradox of the new digital economy" is the contradiction between the significant expansion of digital and economic opportunities of economic systems of the world through the use of new technologies and the lack of understanding of their social significance in the current reality. This contradiction arises from two circumstances. First, when determining the vector of digital development is not always put at the forefront of human well-being, often priority is given to achieving leadership in the "race of technologies" to the detriment of human interests. Second, the transition to another economic formation requires changes in the social construct of value, which can only be achieved in the long term. The solution to this problem is to review the role of the state in the process of forming a given socio-economic orientation and

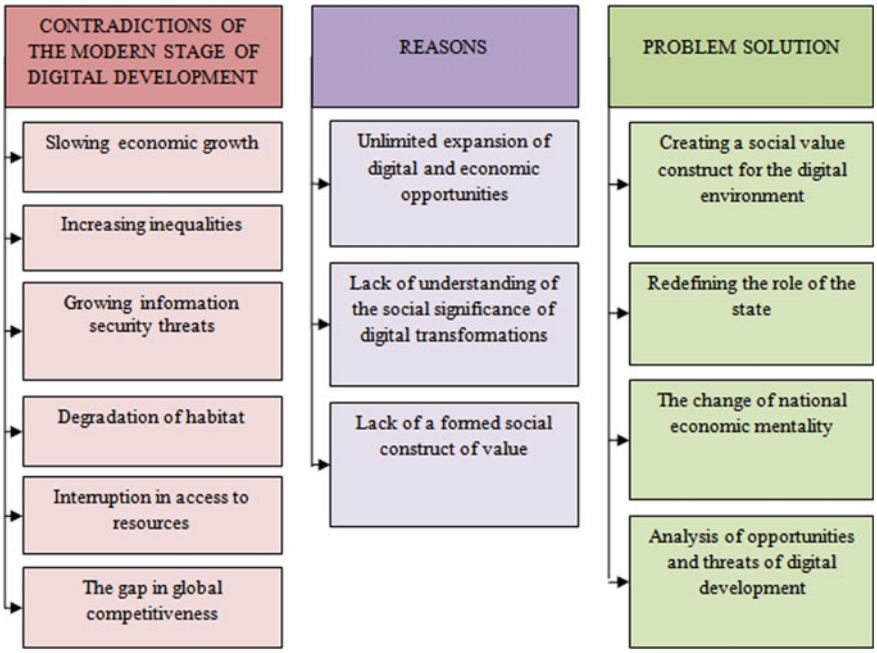

Fig. 1 The concept of the scientific research

behavioral attitudes in society in accordance with the strategy of digital development. The concept of scientific research is presented in Fig. 1.

The authors used scientific statements and hypotheses of various scientists to reveal the specifics of digital transformations and the role of social changes in them:

- Negroponte formulated the concept of "Digital Economics" and noted that the information age, the era of computers give economies of scale, but with less respect for space and time. As we approach the digital world, a whole sector of the population will feel disenfranchised, including due to the lack of digital sustainability [14].
- Loebbecke and Picot pointed to a reduction in transaction costs by reducing the cost of collecting and processing information in a digital environment, which is transforming business models and society and requires building knowledge and developing new high-tech and cognitive skills to cope with the threat of replacing it with new technologies [11].
- Toffler A. argued that social change increases the gap between existing images and the reality they should reflect. When this gap is small, the person is able to cope with the changes and reasonably counteract the circumstances. However, when this gap increases, the person becomes less able to cope, weakly reacts, retires or just panics. When this gap increases to the extreme (as in the case of

intensive digital development), the person begins to experience psychosis or even dies [23].

- Auzan A. put forward the hypothesis that the cardinal reduction of transaction costs, as well as the expansion of exchange options (according To D. North) and the emergence of new elements of the spectrum of discrete institutional alternatives lead, on the one hand, to an increase in opportunities, and on the other hand, to conflict development [1]. The author justified the emergence of two supra-constitutional institutions that have the greatest impact on the processes of socialization in the digital space: (1) the development of artificial intelligence, replacing the natural intelligence and the person himself and requiring the principle of creativity together with the principle of satisfaction in the implementation of limited rationality; (2) the sale of customized effects, which replaces the sale of goods and services, which entails the possibility of disappearing the problem of consumer choice and satisfaction of maximizing business aspirations in exchange for severe forms of hidden dependence and requires the formation of new value constraints in the structure of informal institutions.

Indeed, the dynamics of the modern stage of digital development indicates the need to integrate new phenomena of the digital environment in the traditions and values of daily life and the formation of a new social construct of value.

According to Sologubova G. S., the social construct of value is a model of explaining the world, a certain evaluation template created by an individual, through which he "understands" the existing reality [20].

Value orientations determine the structure of the social structure components and influence the content of the guiding principles of human behavior in situations of a certain kind through cultural values, values of civilization, moral values, moral values, ideological values, scientific values, the value of life, family values, values of Orthodoxy and others.

In his research, Slivotsky proved that the transition to the digital stage of development is associated with the migration of value, that is, the mechanism linking the traditional business model and the structure of human priorities becomes outdated or breaks down [19].

The author's conclusions about the need to review the role of the state in ensuring digital transformations are based on the theory of D. Stiglitz, according to which state regulation should level out the deformations that prevent the formation of a new formation model [21].

3 Results

Organization for economic co-operation and development (OECD) experts compare the current stage of digital development with "an expanding society" [15]. Indeed, the growth of opportunities for the realization of human potential, the intensive spread of innovations, the expansion of access of various categories of users to

Internet resources and the use of mobile data technologies, the creation of artificial intelligence technologies and the development of the Internet of things are becoming a source of greater economic benefits and economic growth [10]. Thus, from 2006 to 2016, real value added in the digital sector grew by an average of 5.6% per year, outpacing the average annual growth rate of the entire economy by 1.5%. In 2016, the digital economy made a significant contribution to the overall economy-accounting for 6.5% of GDP in current dollars, 6.2% of gross output in current dollars, 3.9% of employment and 6.7% of employee compensation [2]. The volume of exports of high-tech products in the developed world in 2016 amounted to a total of 2, 56 trillion dollars (including in the United States-303 billion dollars; Japan-122 billion dollars; China-615 billion dollars). In 2016, the global e-Commerce market reached 25.3 trillion dollars: 90%—between enterprises, 10%—between enterprises and consumers [24]. The use of digital technologies in the period from 2011 to 2016 reflected overall growth in factor productivity, i.e. the combined growth of inputs, such as resources and labor, and output-it grew by 0.3% in advanced economies and by 1.3% in emerging and developing economies [25]. In addition, all regions and groups of countries have made significant progress in terms of human development during this period. The dynamics of the Human development Index (HDI) confirm this fact [16]. The global Human Development Index at the beginning of 2017 reached 0.728–21.7% higher than in 1990, when it was 0.598. United Nations experts say that people around the world are living longer, more educated, and have access to greater life opportunities [16].

However, data from the 2019 reports on global digital development and productivity by industry indicate structural changes in productivity due to digital transformation and slowing economic growth in various countries around the world [3, 25]. Moreover, experts say that over the past decade, growth in advanced economies has been anemic, many developing economies (including Argentina, India, Brazil, Russia and China) have experienced a slowdown or stagnation, and in the least developed countries, growth rates have been and remain significantly below potential and are unsustainable [3].

According to recent estimates, the downward trend in global productivity growth is 2.3% on average per year between 2010 and 2017 [22]. The data also suggests that the long-term effects of digital transformation on productivity are still too small to be seen in long-term improvement at the macroeconomic level. Of course, there is a significant differentiation that defines the gap in global competitiveness: for example, in the US, productivity growth was only 0.6% from 2013 to 2017, of which as much as 0.5 percentage points (or 86%) were accounted for by digital production, representing only 8.2% of US GDP. In the European Union, the digital manufacturing sector has shown a strong decline in its contribution to productivity growth, which by 2013–2017 was only one-third of the US contribution at 0.15 percentage points. However, the most digitally intensive industries contributed 4 times more to productivity than in the US, resulting in an overall increase in productivity from 2013 to 2017 to 0.9 percentage points [3].

Another aspect of the modern stage of the digital economy—human development—is also undergoing changes. The report “Updated statistics 2018” presents

HDI values for 189 countries and territories and notes that recently "progress is not straightforward, and the goal is still far away". Experts note a slowdown in HDI growth: taking into account the inequality of the global HDI for 2017 decreased from 0.728 to 0.582, that is, the average decrease in the value of the global HDI due to inequality is about 20% [16]. In addition, the degradation of habitat and atmosphere, combined with a significant reduction in biological diversity, threatens the human development of present and future generations.

What is the reason for the so-called "productivity paradox of the new digital economy", which points to the idea of increasing spending on digital technologies and human capital development without a noticeable increase in economic productivity and human well-being? Why do the economic opportunities of economic systems of the world's countries that are expanding due to the use of new technologies not provide a paradigm shift of the new economic reality: from "man for the economy" to "economy for man"? [6].

Perhaps the current situation can be explained by the global food, financial and economic crisis, the achievement of growth limits for individual components of HDI (for example, the biological limit of life expectancy; the duration of education and the degree of coverage of education, the achievement of economic maturity).

Perhaps the problem lies in the lack of understanding of the social significance of digital development in the current reality. Thus, when determining the vector of digital development is not always put at the forefront of human well-being, often priority is given to achieving leadership in the "race of technologies" to the detriment of human interests. For example, when developing concepts and strategies for digital development, some countries of the world replace the tasks of solving social problems, reducing the social, economic and psychological risks of digitalization with the achievement of technological leadership and economic modernization. For example, the concept of "industry 4.0" clearly gives priority to the technological and economic imperatives of development that provide Germany with technological leadership, while the social well-being of the population is poorly reflected in it, except for the creation of additional jobs needed to expand the country's productive power [7].

In our opinion, we need to look for the answer in the content of the digital transformation itself. After all, at its core, digital transformation is not only a process of investing in the introduction or expansion of the use of digital technologies to create new products, but also a profound transformation of the entire value chain of new products, implemented business models, interaction between consumers and manufacturers, and, of course, the creation of a new social value construct that leads to long-term productivity [26]. While the first component of digital transformation is fully implemented in different countries and demonstrates high growth rates, the lack of formation of the second component entails a wide range of difficulties that increase the cost of transition, and requires time for adaptation and adjustment [13]. Indeed, social constructs of value allow us to integrate new phenomena into the traditions and values of daily life by changing the structure of the components of social structure, the nature of economic relations and influence on the content of the guiding principles of human behavior in certain situations [20].

When the mechanism linking the traditional business model and the structure of consumer priorities becomes obsolete or breaks down, value migration begins [19]. Value for the consumer in the digital environment is manifested in the degree of his satisfaction with the consumption of goods and services, his emotions, determined by the possibility of participation in the process of creating value, as well as in the ability to manage the processes of product delivery from the manufacturer using digital technologies [18].

The value for the manufacturer consists in additional opportunities for business development and product improvement through continuous interaction with consumers, joint creativity in the process of developing new products, creating communities of interests and qualifications. In addition, the use of digital technologies allows the consumer to get additional value from the convenience and speed of the entire chain "raw material-product-service-satisfaction", and the manufacturer acquires additional value in the form of an increase in the global market share [9].

Thus, the change of priorities in the value structure gradually forms a socially accepted and recognized social construct, that is, a special attitude to the needs that determines consumer choice, business supply, and the quality of the institutional environment. According to the theory of economic transformation, the transition to another economic formation requires changes in the social construct of value, and this can only be achieved in the long term (Fig. 2).

Rapid informatization and introduction of digital technologies in all spheres of life of society did not allow to form a new social construct of value in many countries, which caused the emergence of a whole range of new social problems. Society was not ready for them.

Deprivation of personality leads to an increase in the level of anxiety, the emergence of a sense of manageability and a sense of insecurity, that is, the psychological consequences of "digitization of personality". This violation of the boundaries of personality is the result of a lack of understanding of the specifics and capabilities of information technologies, as well as ways of using them by a person. The basis for maintaining basic "information personal hygiene" and preventing violations of identity boundaries is the awareness that technology is not neutral towards the user [8].

The cultural and moral unpreparedness of a person for his new role and functions is manifested in the process of transition to a new formational model. This is fraught with the satisfaction of his interests by any means leading to the destruction of all that has raised him to a qualitatively new social level and expanded his life opportunities. As a rule, the occurrence of such situations entails "regression and rollback in the society development" [17].

In our opinion, the revision of the role of the state in the process of forming a given socio-economic orientation and behavioral attitudes in society in accordance with the strategy of digital development, that is, the construction of a social value construct can be a solution to this problem. During the transformation period, the state assumes the function of forming an ideological base that reflects the migration of value in the digital environment, the group self-identification of various political actors and the peculiarities of the national economic mentality [12]. Changes are

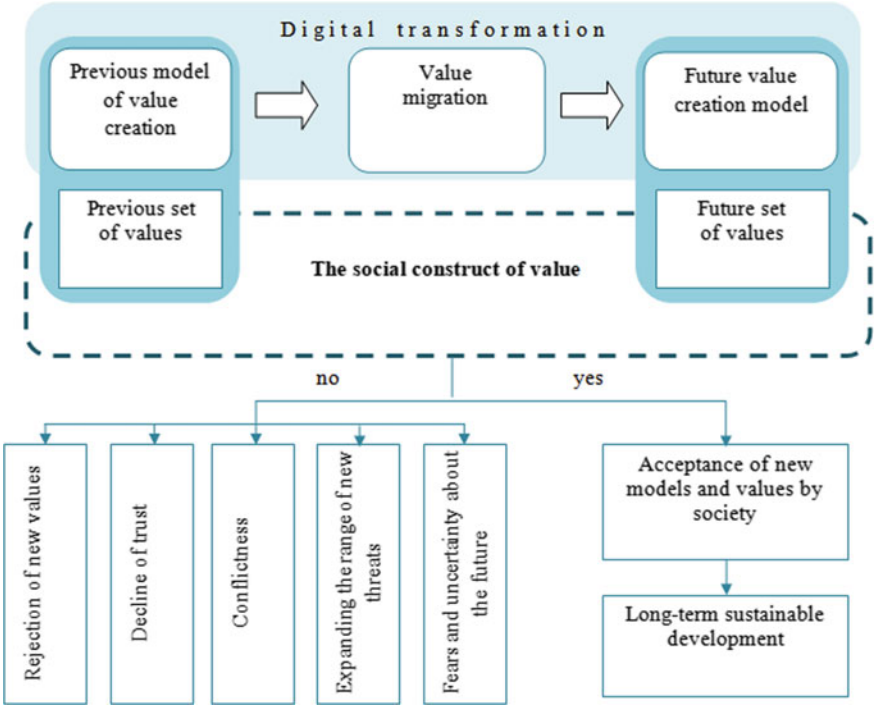

Fig. 2 Social value construct as a basis for digital transformation

initiated by the state and reflected in the new system of institutions that form the basis for the economic development of any country. A timely and complete analysis of the features of their formation allows us to assess the system of values that reflect the directions, goals, scope and priorities of economic activity due to cultural and historical development. Naturally, any interaction with state and public institutions should contribute to the formation and effective implementation of promising strategies of socio-economic behavior. This also applies to situations where "choice errors" are detected, where available resources may be under-or over-valued, or may not meet their goals. In addition, creating a positive attitude and understanding of the need for change in the public mind should become an integral part of the process of forming the economic mentality of the nation in emerging digital society.

The task of the state in these conditions is to prevent the creation of an internal conflict of individuals to the established mental structures of their consciousness, to level the feeling of fear and uncertainty, to produce new ideals and values, to form the ground for leveling new threats and dangers of the digital environment, preventing their occurrence of negative consequences. In the conditions of digital and information development there is a phenomenon of openness of forms and technical possibilities of social communications that creates preconditions for "invasion" in mental structures of consciousness of members of society. Such an environment

should contribute to the formation of stable worldview invariant structures that will act as normative and cultural-value criteria for the selection and assimilation of large amounts of information.

4 Conclusions/Recommendations

The study of the dynamics of socio-economic development allowed us to identify structural changes in labor productivity caused by digital transformations, and the slowdown in economic growth in various countries of the world against the background of increased spending on digital technologies and human capital development, that is, to note the emergence of "the productivity paradox of the new digital economy". The study of the essence of digital transformation as a process of deep transformation of the entire value chain of new products, implemented business models, interaction between consumers and producers, and the creation of a new social value construct that leads to long-term productivity, allowed us to conclude that there are socio-value causes of "the productivity paradox of the digital economy". The author's vision of the process of forming a new social construct of value for the digital economy is presented. This requires reviewing the role of the state in creating socio-economic orientation and behavioral attitudes of society members, changing the national economic mentality, as well as creating a positive attitude and understanding of the need for digital transformation in the public consciousness, taking into account the opportunities and threats of the new digital environment.

Bridging the Generation Gap with Net Students

Maria V. Arkhipova, Ekaterina E. Belova, Yuliya A. Gavrikova, Tatyana E. Nikolskaya, and Elina D. Shapiro

Abstract The article presented aims at describing the educational needs of the new generation of learners, specifically Generation Net. We examine generational differences between the Boom Generation, Generation Y, Millennial and Generation Z cohorts. The Strauss-Howe generational theory constituting the basis of our research, we give the interpretation of the generation gap in Russian reality. We present the statistics on faculty-student belonging to a particular generation cohort at Minin University, Russia, and explore the relationship between the former and latter generations. We conclude that the traditional sage-on-the-stage approach used in most Russian universities does not work in dealing with the current Generation Net representatives. There is an urgent need to find new teaching approaches to reach the new generation of learners that will help meet their educational needs, goals and values. We see the way of improving the quality of teaching in introducing the latest technologies that are able to bridge the generation gap, boosting academic achievement.

JEL Classification I25

1 Introduction

According to Oxford Dictionary generation gap is "a difference of attitudes between people of different generations, leading to a lack of understanding" [16]. As stated by Smith [24], the term "Generation" variously refers to (1) ascending and descending lineage; (2) immigration and nativity status; (3) birth cohorts; (4) life stages.

Generations are shaped by the events and circumstances taking place at a particular time, globalization, gentrification, migration, urban transience, digitization all together contributing to the generation gap [11]. To better understand generations and existing generation gap between them, it is necessary to define generational cohorts, examine their nature and in this way infer their values, goals and basic needs. Notable differences between generations are to be taken into consideration while speaking about creating effective educational environment. It seems impossible to interpret the faculty-student relationship between the former and the latter generations not knowing what type of cohort they belong to.

2 Background and Methodology

One of the earliest theories of generations goes back to Howe and Strauss, introducing a sequence of generations and the generational types with their distinct beliefs and behavior patterns. The Silent Generation (born 1925–1942) grew up as the seen-but-not-heard members, climbing the career ladder as a firm guarantee of success. Conforming to social norms the people tended not to risk to speak out. The Boom Generation (born 1943–1960) had community strong spirit, at the same time seeking inner life and self-perfection and redefining traditional values. The generation is characterized by a strong cultural cleavage which is explained by the historic and social changes. The people described themselves as "the arbiters of the nation's values, crowding into fields like teaching, religion, journalism, law, marketing and the arts" [10, p. 45]. Generation X (born 1961–1981), mostly having a latchkey childhood background, has a practical and entrepreneurial mindset. They tend to be individualistic, believing one-on-one help to be more efficacious. The Millennial Generation (born 1982–2005) is more conventional following family values and avoiding high-risk behavior. They are high-tech savvy, civic-minded, putting emphasis on work-life balance. The Homeland Generation (born 2005–2025) is comfortable with technology interacting on social media. The generation is arriving in nurseries, so "it is still too early to set their first birth year, which will become clear in time" [10, p. 45].

There may be arguments and criticism found about generational differences and conclusions drawn by Howe and Strauss, stating there is no solid evidence on how the

research was conducted [3, 14, 30], regional differences reflected sufficiently, much less relating to socioeconomic status, culture, race and other significant factors [17].

There is a significant disagreement on how to label generations, various synonymous terms provided by the researchers, as well as on their characteristics and chronology, span of years varying from author to author. Thus, Stillman and Lancaster [25] distinguish Traditionalists (born 1900–1945), Baby Boomers (1946–1964), Generation Xers (1965–1980), Generation Y/Generation Next (1981–1999). Tapscott [26] refers to Baby Boom Generation (1946–1964), Generation X (1965–1975), Digital Generation (1976–2000). Oblinger and Oblinger [15] present a classification describing Matures (1900–1946), Boomers (1946–1960), Gen-Xers (1965–1980), Gen-Y/NetGen (1981–1995), Post-Millennial (1995–present). Other alternative names for generation groups include Generation We [7], Global generation, the Net Generation [21, 22], iGeneration, Gen Tech [9, 18], Digital Natives [8].

Despite the existing inconsistency in terminology and chronology, the researchers agree that distinguishing features within a given generation group exist, though one should be accurate in making assumptions about any individual based on their belonging to a defined generational cohort [17].

The theory of generation, firstly introduced relating to the USA background, has evoked a widespread response throughout the world, including Russia. The Russian theory of generations is scrupulously described by Shamis and Nikolov launching the project "RuGenerations". The theory of Howe and Strauss has been adapted to Russian reality, significant historical events and turning points occurring during each generation formative years, their common beliefs, behaviors and perceived membership described by the authors (shown in Table 1).

The values of present-day students are seriously taken by the higher education faculty, managers and administrators urging to adjust teaching methods to the needs and preferences of the new generation of students. A wide generation gap existing between faculty-student members is one of the factors contributing to misunderstanding between representatives of different generations. Students' determination and aspiration, core values and needs are developing and changing while teaching techniques lag behind. Twenge [31] analyzed attitudes of the Baby Boom Generation and GenMe, the finding based on the data gathered from 1.3 mln. Americans, the results of the studies proved generational differences in learning attitudes and preferences. For instance, 18% of freshmen in 1968 reported being A-students in high school compared to 48% of American high school students in 2004. 12% of young teens in 1950s agreed with the statement "I am an important person" compared to 80% by the late 1980s. Only 28% of Boom mothers agreed with the idea that a person's main responsibility is to themselves and their family and children rather than making the world a better place compared to 53% of GenMe mothers.

The current generation is more technologically savvy with information technology being an integral part of their life. They easily adapt new online resources for their needs. They are described as highly entrepreneurial and pluralistic, determined to take charge of their own social, economic and educational programmes [13]. While organizing the educational process it is of vital importance to take into consideration

Table 1 The Russian theory of generations according to Shamis and Nikolov

Generations in Russia	Years of birth	Historical events and turning points	Characteristic features
Greatest generation	1900–1923	World War I, revolutionary events of 1905 and 1917, collectivization, electrification	Industry, responsibility, religion-like belief in the rosy future, commitment to ideology, family and family traditions, dominance and flatness of judgment
Silent generation	1923–1943	Stalin's repressions, World War II, restoration of the destroyed country, discovery of antibiotics	Devotion and loyalty, rule- and law-abidance, respect for job title and social status, honour, patience
Baby-boom generation	1943–1963	The Soviet thaw, conquest of space, the USSR—the world superpower, the Cold War, first plastic surgery, creation of contraceptive pills, common standards of education in schools and guaranteed medical care	Optimism, interest in personal growth and reward, but collectivity and team spirit, youth cult
Generation X	1963–1984	Continuation of the Cold War, perestroika, drugs spread, war in Afghanistan	Readiness for changes, potential for choice, global knowledge, IT-literacy, individualism, pursuit for life-long learning, informality of views, search for emotions, pragmatism, self-reliance
Generation Y	1984–2000	Collapse of the USSR, terrorist attacks and military conflicts, SARS, development of digital technologies, mobile phones and the Internet	Civic duty and high morals, responsibility, as well as/but naivety, ability to submit, instantaneous reward
Generation Z	2000–2016	Development of the Internet, smartphones, consumer products	Irresponsibility, mass obsession with fashion

their information-age mindset. The current generation is independent and makes their own decisions relying on information found on the Internet.

The faculty-student relationship is a complex phenomenon, posing a myriad of challenges. Generation Z is more interactive, so the students are likely to experience concentration problems while dealing with strict Baby Boomer faculty members

tending to run the classroom in a more conservative orderly fashion. The traditional teaching approach may fail to be effective, as it no longer meets the learning styles of a new generation. Tran and Anderson [29], providing an example of the School of Science and Technology Georgia Gwinnett College, USA, state that the average age of faculty is 42.5 years old, whereas of undergraduate students is 23.5 years old. Therefore, they see the use of technology by the faculty as a way helping the faculty-student relationship thrive and foster both teaching and learning.

Quite few researches relating to the notion of generation gap in academic education context have been made in Russia so far. Modern society is described as "a new informative habitat of people" [2, p. 1165]. They see information technologies as a facilitator helping students assimilate scientific data, stimulating critical thinking.

IT is an indispensable element in the learning process, as both teachers and students make use of different software or gadgets in classrooms or while studying at home. Trajnev [28] reveal the historical phases of IT development, disclose its concept, describe different types and research the importance of using IT in education. Shadrikov and Shemet [20] devote their study to the advantages and disadvantages of information technologies in education. From their point of view, the value of IT in education lies in the multimedia approach to education, access to a variety of learning resources helping to focus on each student's abilities and strengths. On the other hand, computerized education can lead to a lack of communication between a teacher and a student. This gap in communication in its turn creates distance hampering the teaching-learning process.

The increasing importance of the Internet in everyday and working life of the average Russian citizen (57.7% in 2016, in contrast to 51.6% in 2014) is noted by Kozmenko [12]. The Russian government has funded many strategic research and investment programs, but a real prioritization of practice did not contribute to the subsequent recoil. For example, in accordance with the Federal Targeted Program "Electronic Russia", informatization was successful in educational and government institutions: it involved PC equipment, Internet access, creation of electronic representations, automation of work with the population [4, 19, 23, 32]. Computer technologies are meant to become an integral part of a holistic educational process significantly increasing its effectiveness [1, 6, 33]. Innovative approaches to learning on the basis of ICT tools are introduced into the traditional educational process in Russia. There is a process of accumulating experience ways to improve the quality of education and new forms of ICT use are being sought in various educational processes [5, 27, 34]. Russia's participation in international programs related to the introduction of modern information technologies in education as well as creation on the basis of modern information technologies of a unified system of distance education in Russia are some of the ways for the national education system to enter the world information and educational environment.

To better understand the existing generation gap in faculty-student relationship in Russia we present a survey exploring this relationship through the lens of their belonging to a specific generation group, the following questions being the foundation of the research: (1) Is a generation type one of biggest contributing factors that directly

influences the faculty-student relationship? (2) Does the use of technology have an impact on the teaching-learning process?

To reach the aim the following methods were used: theoretical literature analysis, diagnostic method of observation and questionnaire poll.

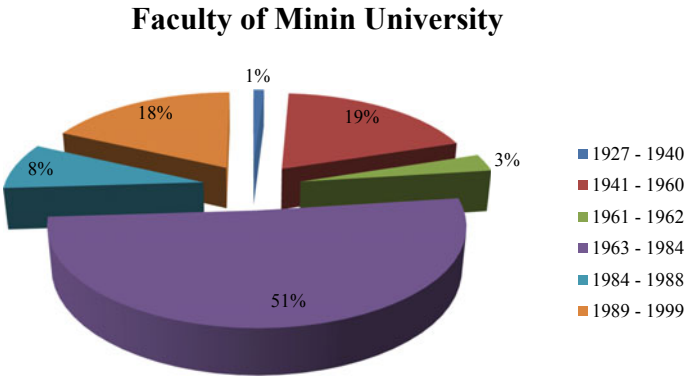
To answer the first question we conducted the research in Minin University, Russia, 9269 teachers and students taken for analysis which helped us analyze what generation type students and faculty belong to.

To answer the second question the authors of the article have developed a questionnaire to be filled in by students of different age groups. The questionnaire clarifies the aim of the survey, contains an instruction on questions of open and closed types including the following questions: "Do you agree with the statement that IT-based classes with the use of technological equipment, for example, with a computer, are much more interesting?", "Would you prefer to study the material of the class with the help of a video clip or a training computer program but not by mere reading?", "How do you assess your emotional state while using an IT-device?".

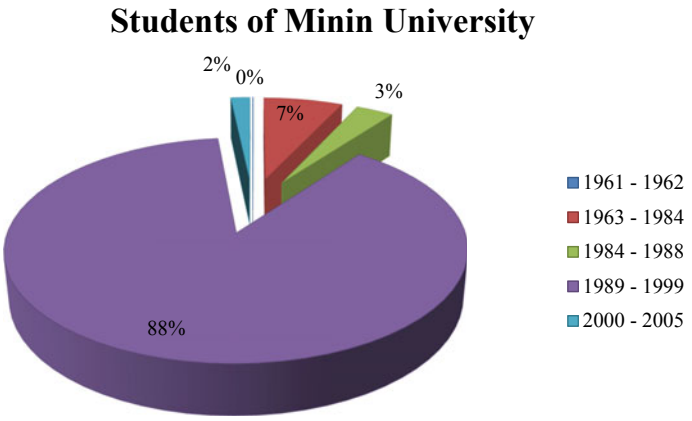
3 Discussion and Results

To analyze the idea whether a generation type is one of biggest factors that directly influences the faculty-student relationship it is expedient to conduct a survey into how various age groups are presented in Minin University.

The research conducted in Minin University, Russia, displays 9269 teachers and students taken for analysis, namely 717 teachers and 8552 students. Among 717 teachers (see Picture 1) there are only 7 people representing the Silent Generation (born in 1927–1940); younger generations which can seem closer in age to students—Generation X and Generation Y, years 1984–1988 and 1989–1999—constitute only



Picture 1 Age groups of the faculty of Minin University



Picture 2 Age groups of the students of Minin University

26% of the whole faculty, 18% and 8% correspondingly. The most populous cohort of the faculty (51%) is of those representing years 1963–1984.

8,552 students (see Picture 2) are not so diversely represented as the faculty, only in 5 categories as of March 2018. The second least represented category is of students born in 2000–2005, the first one being only 0.05%. 3.24% of students belong to Generation Z; the most expanded category is of representatives of Generation Y, born in 1989–1999.

According to the research data, the majority of the students and the faculty of Minin University belong to various age groups, i.e. generations, the faculty being of Generation X and the student cohort belonging to Generation Y. Though these two generations have much in common, as their life coincided with the periods of frightful and ruinous wars, terrorist attacks or military conflicts, they were likely to feel an urge to introduce changes with respect to political, economic, psychological and other spheres of life. As a result, Generation X searched for global knowledge and for life-long learning pragmatically as well as emotionally. Due to the collapse of the USSR and other political cataclysms Generation Y acquired civic duty and high morals, but was made hungry for instantaneous reward. These brief characteristics as well as others introduced in Table 1 cannot but draw the researcher to the conclusion that the above-mentioned generations have the opportunity to coexist, but it is difficult for them to be unanimous in all respects.

Furthermore, it is important to highlight the fact that the average age of the University teachers is approximately 48.2 years old, compared to 23.1 of students.

It should be noted that according to the generational theory each generation sets its own trends in all the aspects of life and that results in their differences. For example, the term “communication skills” may mean formal writing and speaking abilities, in other words, long essays or expanded oral utterances, to an older person. But it might mean a brief superficial e-mail and instant messaging to a twenty-year-old student. The research, as expected, showed generation gaps between the

different forms of technology used. A popular belief held by older generations is that the characteristics of Generation Y can potentially complicate professional, in our case learning-teaching, interactions. To some tutors, this generation is a group of coddled, lazy, disloyal and narcissistic young people, who are incapable of handling the simplest task without guidance. These traits could not but influence the learning-teaching process anywhere.

The second stage of the research is to define if the use of technology has an impact on the teaching-learning process and what it is like. The questionnaire containing 3 questions to students of different age groups is supposed to size the possibilities of classes with the use of various technological equipment and assess the emotional impact of IT-classes on the student in general with a view to finding at least one of the ways to bridge the generation gap with IT-natives.

The first question in the research poll was "Do you agree with the statement that IT-based classes with the use of technological equipment, for example, with a computer, are much more interesting?". The respondents' answers show that 70.8% students agree with the statement, 29.2% respondents answered the question in the negative. Thus, IT implementation makes the classes more exciting, according to the majority of respondents.

The second test question is whether respondents agree with the statement "I would prefer to study the material of the class with the help of a video clip or a training computer program but not by mere reading". According to the research data, 75% students agree with the statement, but 25% students would rather stick to the classical methods and still prefer to read the material to absorb and master it.

The question to follow was "How do you assess your emotional state while using an IT-device?". The responses can be interpreted positively, there being none of respondents in a bad mood. The fact is that 20.8% of the respondents stay in high spirits, and their mood boosts, whereas in 79.2% cases the use of IT devices does not influence the mood of respondents in any way.

Thus, the use of technology has a great impact on the teaching-learning process, as is shown, 70.8% respondents find IT-based classes with the use of technological equipment much more interesting and 75% students would prefer to study the material of the class with the help of a video clip or a training computer program but not by mere reading. The fact that in 79.2% cases the use of IT devices does not influence the mood of respondents in any way makes the research complicated, on the one hand, as it proves the idea that students do not derive much fun and pleasure from this kind of activity, but, on the other hand, it makes the researchers understand that use of technological devices is considered to be a trivial customary repeated action like brushing the teeth and combing the hair, therefore, making the learning process much easier and more accessible: there is a wide choice of educational resources, information technology speeds the transfer and distribution of information, learning is not limited to a physical classroom and to any physical time of the class anymore, etc.

In this connection in Minin University learning environment is easily provided through Moodle, the acronym *Moodle* standing for *modular object-oriented dynamic learning environment.* This eLearning platform enables students to access academic

information in various formats, including videos and graphic illustrations, on time and do the studying process online, the faculty also benefiting from its opportunities changing the process of teaching for the better by means of creating and delivering academic data to all the students simultaneously and by being given the opportunity of checking certain tasks not in hand but by computer technologies, i.e. electronically.

Numerous Moodle online courses are bound to influence students' motivation for learning and learning results and their study is seen as the perspective of the current research.

4 Conclusion

Intergenerational relationships have been an evergreen and complex problem. The conflict between generations in the process of education is natural. The analysis of the contemporary situation in the society as a whole and in education in particular, allows us to conclude that the self-reliant teachers, eager for life-long learning, and therefore, IT-literate, but still not net natives, have to deal with generations of narcissistic, dependent in the educational process, spontaneous and young net natives. The students' being unable to perform various tasks independently is accompanied by clip-consciousness of their mindset and lack of extensive reading habit which hinder knowledge, intelligence and degree acquisition. Therefore, it is vitally important for the faculty to competently find clever ways and professional possibilities of making use of students' disadvantages and turning them into advantages both in the educational process and in all aspects of life. It is important for the older generation which is a priori wiser and more experienced, to make the first step for mutual understanding. The only thing for them to do is to try to understand the students as there is no choice and there are always people with opposing values and opinions around to teach. Therefore, the very approach to learning and methods of study need to be reviewed, retaining only the overall course program.

All in all, the current research is local and does not cover other universities. On the other hand, it shows the existing picture and the problems of misunderstanding between the students and teachers, representatives of different generations.

The findings of the research prove the vivid and clear generation gap existing between students and faculty in their attitude, opinion and choice. We find the results helpful in making inferences about how the faculty and students may differ in their approaches to learning environment. These inferences lead to a conclusion that age differences are sure to have a considerable impact on both teaching and learning processes. We believe that our findings provide a balanced view on perspective towards understanding the generation gap in higher education.

In order to foster academic achievements teachers need to tool up for change not to lag behind. The generation gap is sure to be an inevitable barrier in terms of communication and attitudes towards perceiving information. Though there is hardly any clear-cut and unique solution on how to bridge this gap, but it seems highly possible to do it through the use of technology. Technology being ubiquitous, we

consider it as an authentic and collaborative tool helping teacher-student interaction in classroom. To try the use of modern ICT tools may help solve the generation gap problem. Implementing ICT tools enables the older generation to approach the so-called Information society which provides for the future, based on the integration of new ICT with educational technologies, i.e. creation of new computer systems, the Internet development and convergence of information and telecommunication technologies.

Perspectives and Restraining Factors of HR Analytics in the Conditions of Digitization of Human Resources Management

Valeriya G. Konovalova, Ruben V. Aghgashyan, and Svetlana S. Galazova

Abstract This paper presents the results of analysis of the modern state and potential advantages of using HR analytics for increasing individual and organizational effectiveness and the perspectives of its further development in the conditions of digitization of HR management. The authors determine the stages of development and maturity of HR analytics in companies and consider their specific features and priorities; determine the potential advantages of expanding the practical usage of predicative HR analytics, including substantiating the necessity for changes in HR management, evaluating the relevance of the used HR programs and tools, accelerating the process and increasing the systemic character of managerial decisions making, as well as creating the basis for strategic partnership of HR specialists and managers. Based on generalization of the empirical data, which were obtained in the course of global and national research, the authors substantiate a conclusion on high demand of predicative HR analytics in solving the following tasks: forecasting the need for personnel and its turnover, increasing effectiveness of recruiting, determining the most valuable employees, talent management, managing the involvement, determining the key factors of motivation and successfulness, increasing labor efficiency, and improving interaction between employees. Based on the performed research, the authors determine a range of the key factors that restrain application of HR analytics in Russian companies: the problem of receiving objective data, insufficient level of information technologies, absence of the necessary analytical competencies with specialists, existing corporate culture, interest of top management. The problems of ethics, confidentiality, and personal information protection during usage of HR analytics, predetermined by application of new technologies and

non-traditional sources of data in case of absence of a clear normative and legal basis (including the risk of prejudice and reproduction of discrimination practices, and reduction of personnel's trust to the company), are analyzed. Recommendations for overcoming the determined problems of development of HR analytics are offered.

Keywords Digitization of HR management · Predicative HR analytics · Big data · Personal data · Integrated prejudice

JEL Classification J5 · J71

1 Introduction

Economic instability makes companies pay more attention to managing the activities' effectiveness, creating a balance between development and preservation of the best employees, on the one hand, and optimization of expenditures, on the other hand. Making managerial decisions based on popular (but not always confirmed in practice) managerial postulates, non-systemic benchmarking, and unverified recommendations, but not based on correct information, top managers put their companies under unjustified risk.

In the course of digitization of HR management, expansion of capabilities of HR analytics and usage of Big Data and Data mining in the sphere of HR management turned into very significant and perspective trends [15]. Methods that allow for data processing are built in most ERP systems, tools of involvement research, modules of text and semantic analysis, and program platforms of hiring and training management—which allows specialists to obtain information and use it for increasing the organizational effectiveness. Despite the expanding opportunities, the level of usage of the function of HR analytics is not equally high in companies, including Russian ones.

2 Background and Methodology

The purpose of this paper is to evaluate the achieved level, perspective directions of development of HR analytics in the context of digitization of HR management, and new opportunities, as well as determining the main restraining factors and problems and risks.

For achieving this goal, the materials of a range of global and national studies on the problem of HR analytics have been generalized.

HR analytics is treated as an approach—which is based on factual data—to optimal decision making, which includes a lot of tools and technologies.

Dave Ulrich distinguishes four stages of development of HR-digital in companies [8, 24]:

1. HR efficiency (investing in the existing digital platforms that ensure management of the key HR processes—e.g., Oracle, SAP, SuccessFactors, Worday);
2. HR innovation/effectiveness (implementing innovative apps, which ensure update and increase of effectiveness of the key HR processes, including management of adaptation, efficiency, and communications—e.g., Dynamics 365 h);
3. Information (using digital technologies for integration of internal and external data, increase of their accessibility, and creation of important presentations);
4. Connection/experience (using digital technologies of creation of deeper communication and feeling of belonging, development of social connections, and development of employees' experience).

The presented model shows that HR-digital leads to expansion of usage of HR analytics and its application primarily for strategic decisions.

According to the approach offered by Bersin by Deloitte [3], it is possible to distinguish four levels of maturity of the function of HR analytics in companies (Table 1).

The value of HR analytics is determined by the systemic approach and regular work with information, but in the course of growth of interest in analytics more companies expect from HR departments and specialists not only sufficient data on personnel but also precise forecasts that are based on HR analytics.

In the course of expansion of the possibilities of obtaining data for decision making in the sphere of HR management, there appears a necessity for specifying the used notions. Together with the notion "HR analytics" (Human Resource Analytics), which is associated with the functions of personnel management departments and traditional metrics, the term "people analytics" is also widely used—it is offered by Google for describing the approach to management based on data and focuses on the fact that analytics supports a wide circle of decisions that are connected to people. Though the term "HR analytics" is the most popular one, the term "workforce analytics" is also used—it reflects the growing practice of usage of metrics and tools for obtaining the full and comprehensive understanding of workforce efficiency. Workforce analytics takes into account a wider circle of factors (gaps in skills and demographic problems, local problems of organization's location, etc.), which influence the efficiency. Besides, workforce does not consist only of humans, but includes also robots and chat bots.

Appearance of the term "Digital Relationship Analytics" reflects another perspective tendency—"from human analytics to analytics for humans". Thus, Organizational Network Analysis (ONA) allows companies—due to progress in technologies—obtaining objective information (without using surveys) on employees' work and interaction. For this purpose, meta data of e-mail, phone, social media (internal and external), cooperation platforms, etc. are used.

Table 1 Levels of maturity of the HR analytics function

Level	Specific features and priorities	Examples of measuring
Level 1: Reactive reports	Preparation of reports on quality of the processes of HR management in the company according to the managers' queries. Unilateral approach (only data). Foundation on past experience during preparation of reports	FTE, turnover of personnel, expenditures for personnel, and expenditures for training and recruitment
Level 2: Proactive HR	Systemic preparation of reports that contain comparative data on personnel management, which could be used for decision making and benchmarking	Time spent for closing a vacancy; time spent for conclusion of a contract; cost of hiring; complex evaluation of selection and adaptation; evaluation of quality of services of HR specialists
Level 3: Strategic analysis	Systemic preparation of analytical reports in personnel management, in which modeling, segmentation, functional analysis, and evaluation of effectiveness come to the foreground. The decisive role belongs to the data that help forecasting the risks. Orientation at optimization of the main processes. Influence on business is evaluated. The data for analysis are taken from several source	Scoring risk (forecasting the outflow of personnel); forecasting of efficiency; determining the characteristics of successful hiring; determining the characteristics of employees who show low/high efficiency, etc.
Level 4: Forecasting analytics.	Creation of predictive models, description of possible scenarios of events, analysis and reduction of risks and integration of HR analytics with strategic planning in the company. Creation of competitive advantages by means of optimization of business processes. Usage of several sources of data	Reduction of the risk of road accidents by forecasting drivers' behaviors based on the tracking data; reduction of idle period of the production line by means of better training of the operator, including on the issues of security, etc.

Source Compiled by the authors based on Bersin [3], Fink and Sturman [6], Marler and Boudreau [15], OrgVue [17]

3 Discussion and Results

Generalizing empirical data on practical usage of HR analytics (including predictive analytics) for improving the quality of managerial decisions in Google, Shell, Nielsen, ISS, Opower, Gap, Microsoft, ATB Financial, Cisco, BNY Mellon, LinkedIn, ABN AMRO, IBM, Coca-Cola Enterprises, Walmart, Salesforce, JetBlue, Virgin Media, Unilever, Nestlé, etc. [1, 7, 10, 16–18, 23], it is possible to distinguish a range of potential advantages from expansion of the practical use of predictive HR analytics for increasing the effectiveness of managerial decisions [1, 6, 15, 19]:

- understanding the causes of the problems of HR management, determining new regularities and interconnections, and substantiating the necessity for changes;
- possibility to evaluate the relevance of the used HR programs and tools;
- time reserve for preparation (determining the tendencies and potential problems allows for targeted change of approaches to management, reducing the damage or preventing it);
- accelerating the process and increasing the systemic character of managerial decisions (approaches of predictive analytics are more integrated as compared to traditional HR metrics, allow trying various variants, and changing conditions and hypotheses for checking the result; such models stimulate the systemic character of managerial decisions, help avoiding a lot of errors due to preliminary testing, and the possibility of access to the most precise and recent information accelerates the process of decision making);
- creating the basis for strategic partnership with the management (analytics could help HR specialists persuading the managers to following their recommendations, showing the ability to forecast and evaluate the influence of HR programs on the business indicators); besides, using interactive analytics, managers could find in Big Data the answers to the questions regarding personnel management.

4 HR Analytics: Adoption and Implementation

According to the international research of the global HR trends by Deloitte [5], 81% of respondents consider usage of HR analytics to be one of the most important tendencies, and 70% are at the stage of implementing large projects on integration of HR data in the processes of decision making. 55% of respondents in Russia said that HR analytics (demographic and organizational data on employees, cognitive data on peculiarities of behavior, and motivating/demotivating factors) becomes more important for decision making in their companies.

Among the companies of the third and fourth levels (according to the model of Bersin by Deloitte), 90% have precise and up-to-date data, and 95% have implemented the policy of provision of secure data. These leading companies perform monitoring of data from a lot of sources, including social networks (17%), surveys (76%), and integrated data from the systems of employment management (87%) [1].

According to the global research by KPMG [13], analytics is one of the three main reasons of investments in HR technologies (companies plan to invest in technologies—e.g., RPA—which expand the possibilities of integration of data from various sources and their analysis in real time, for understanding the signals that show the emerging problems in the future two-three years).

In different companies, the level of development of the HR analytics is different. According to the research by CIPD [4], 37% of HR leaders state that analytics is a part of competencies of HR specialists and three companies out of ten have specialists on qualitative and quantitative analysis and the same number of companies use the services of hired experts. 8% of HR leaders acknowledge that they do not use the tools of HR analytics, and a lot of them just start using them; 25% of respondents state that their companies have a department of HR analytics, the process is standardized and the set of metrics is approved. 7% strive to expand the analysis methods and use forecasting analytics for management the business's effectiveness. Opinions of HR leaders and other top managers regarding the future value of HR analytics are different. While 78% of HR directors think that HR analytics stimulates understanding of the strategic role of HR, among other managers only 49% support this thought. 70% of HR leaders are sure that in ten years predictive analytics will become a standardized HR function.

According to the research by Economist Intelligence Unit on behalf of KPMG International [13], 55% of respondents are skeptical regarding the potential of evidential HR management and use of HR analytics for improving business results. Most of the managers (70%) expect that their organization will increase the practical usage of HR analytics in the next three years.

Generalizing the presented data, it is possible to conclude that there is a mismatch between the examples of positive influence on business and the decisions to adopt and implement effective HR analytics.

What is the situation in the Russian practice? According to the 2018 research by Rabota.ru [25], 56% of Russian companies use HR analytics: 24% of them use HR analytics constantly, 32% use it in certain projects, and 11% do not use HR analytics.

Thus, we see that development of HR analytics does not exceed the second level of the Bersin by Deloitte model. The most popular HR metrics, which are used for analysis, are turnover of personnel (82%), movement of personnel (63%), sources of inflow of applicants (61%), payroll budget—fact, forecast (59%), time for closing vacancies (58%). For analysis and presentation of data, most companies use Excel (90%); for HR analytics and its visualization—1C (49%), Word (23%), and Power Point (19%); the leader among specialized programs is E-Staff (15%); only 15% of companies use their own software. Only 7% of Russian companies have an office of HR analytics. According to the research by SAP and Deloitte [20], only 3% of organizations in the modern Russian practice use predictive analysis in HR analytics based on machine learning, 15% store HR data in one integrated system, 35% do not use established processes and systems that support HR analytics, and 60% use standard office applications.

According to the research by SHL Russia [21], HR analytics is often applied not because an organization has to find a solution to a certain problem but because

of the modern trend; or because the company's IT systems have the corresponding functions. Only 53% of organizations use the data of HR analytics in order to show the value of investments in HR management and influence of HR on the results of business. 87% of respondents are sure that their companies will have use personnel data more actively in the future.

5 Restraining Factors, Problems, and Risks of HR Analytics

Comparison and generalization of the data of the above studies allow for a conclusion that the most important conditions of increase of effectiveness of usage of HR analytics are presence of objective data and proper level of information technologies [12].

According to the research by SHL Russia [21], only 3% of respondents do not have problems with collection and processing of data; only one company out of seven has sufficient data for HR analytics. Though analytical technologies become available, only 21% of HR managers are satisfied with the existing IT systems, and 70% consider insufficient integration of TMS to be an important obstacle for effective HR analytics. According to KPMG [13], the factors that restrain the development of HR analytics include company's corporate culture (32% of respondents), absence of necessary skills and resources (30%), and quality of used data (29%). As a means of support, HRM IT/e-HRM should collect, store, and make accessible the data on all functions of the company and created reports, information panels, and systems of indicators—however, real capabilities of the systems are below the declared level: absence, unavailability, or insufficient precision of data are observed.

Another factor that restrains the development of HR analytics is the absence of necessary analytical competencies (basic and intermediary analysis of data, basic and improved multi-dimensional models, preparation of data, analysis of initial reasons, design of research, collection and analysis of quantitative data, etc.) with specialists [19]. HR departments create large arrays of data, but very often they cannot treat them correctly. The results of the research by SHL Russia [21] also show the lack of analytical skills as an important obstacle for application of HR analytics (44% of respondents noted this)—besides, implementation of HR analytics is met with opposition in 33% of organizations.

For HR specialists to obtain access to inter-functional data, managers of other functions must be ready to provide access and participate in this process. Besides, HR specialists have to win the trust of top managers, who might be skeptical towards the results of HR analytics.

We see that the state of HR analytics in the Russian practice is largely predetermines by the specific features of the organizational structure (primarily the functional structure of HR departments, and internal policies and practices are poorly integrated). It is necessary to unify scattered analytical activities, which are already

conducted in the company (analytics of involvement, recruitment, training, etc.). According to the existing estimates [22], only 12% of top managers are interested in evaluating the effectiveness of work of HR departments. If the indicators of evaluation do not help increasing profit and effectiveness, implementing innovations, etc., they do not urge the managers to act. Thus, according to the experts [1, 11], it is necessary to start from the problems that are important for top managers—sales volumes, risks, growth, customer loyalty, etc.

Expansion of use of HR analytics is connected to a range of ethical problems. Collection and analysis of data on workforce without understanding the goals and corresponding communications might cause concern and increase mistrust of the employees to a company. The situation is complicated in case of use of new technologies and non-traditional sources of data (portable devices, e-mail, and social networks): employees often do not see the large number of agents and algorithms that collect and store data for further usage. AI, biometrics and tools that track employees' behavior at work and actions in the Internet lead to input of large arrays of personalized data in the work processes of the organization without a clear normative & legal basis. IBM surveyed 17,432 employees in 24 countries [9] for evaluating the level of sharing personal information with the employer. The research showed differences between countries and within countries in employees' attitude towards information exchange with employers, which means that levels of comfort could—with joint usage of personal data—differ a lot, depending on organization or persons.

According to the research by Insight222, 81% of projects on HR analytics are threatened by the problems of ethics and confidentiality [14]; increase of regulatory requirements in the sphere of information security—especially, protection of personal data—became one of the global trends. Basic recommendations: if you cannot formulate a profit for employee from collection and analysis of his personal data, the project should not be realized. Together with the problems of provision of confidentiality and protection of data on employees in HR analytics, J. Bersin draws attention to the risk of prejudice: the purchased or independently created system of predictive analytics could have integrated prejudice [2]. For example, systems based on AI, which evaluate readiness for work, could reproduce discrimination practices of recruitment (e.g., Amazon); systems that use analysis of the organizational network for determining effectiveness might not realizes that age or sex have an important role in trust and relations, etc. The number of such examples grows. Employers use the technologies of obtaining data and use the data in forecasting models—but the forecasts are not 100% precise. Thus, it is recommended to perform monitoring, evaluation, and training of analytical systems.

6 Conclusions

The most difficult part of HR analytics is to implement recommendations on usage of the analytical models. The performed research allows concluding that application of HR analytics will provide a vivid effect in practice, under the condition of

development of not only analytical skills of specialists but also a skill to explain and implement changes, including overcoming the opposition to changes. During expansion of using HR analytics in the conditions of digitization, it is necessary to ensure the proper level of security, confidentiality, and anonymity, considering the policy of provision of security as an inseparable element of HR analytics management. Because of the growing volume of available data, it is necessary to collect, manage, and use data in coordination with the company's values and according to the legal and normative requirements. The policy of implementing HR analytics should be transparent, and employees have to understand why the management wants to collect personal data and how this could improve their labor life.

The research showed that effective use of HR analytics could raise trust to the corresponding functions and profession on the whole by means of increase of effectiveness of HR policy and practice and significant contribution into increase of competitive advantages of organizations, optimizing the activities of HR-departments.

Global Dimension of Foreign Education Recognition

Vladimir V. Nasonkin, Yuliya O. Sidorova, Yuliya G. Shaporova, and Liudmila A. Bukalerova

Abstract *Goal*: to give consideration to the legal fundamentals in the field of recognition of foreign education in the context of worldwide trends and challegnes in higher education. The authors introduce readers to the fundamental principles of the Global Convention on the Recognition of Higher Education qualifications—a global regulatory act aimed at improving academic and occupational mobility, expanding international cooperation in higher education, recognizing cross-border education and building trust to education systems in various regions. Special attention in this paper is given to Article VII hereof concerned with recognition of the incomplete education of refugees and displaced persons as well as their education certificates. *Methodology*: Research tasks were solved through a comprehensive, complete and objective analysis of norms, Russian, international and foreign legislation, law enforcement practice and analysis of academic works of leading scholars. *Results*: The authors conclude that the ratification of the Convention by the countries will contribute to increasing the degree of openness of education systems and reducing barriers to academic mobility all over the world, as well as improving information support, the process of the recognition and quality assurance of education. Moreover, it is pointed out that it may take a long time for a document of such magnitude to enter into force.

1 Introduction

The modern processes of internationalization of education and the increased scale of academic mobility clearly put on the agenda the need for adoption of a global legal document that would regulate issues of cross-border recognition of foreign education with due consideration of the best practices used in the expert community.

The most significant trends of development of higher education at present include a rapid increase in the number of students of higher educational establishments all over the world, establishment of cooperation between universities and employers, development of modern technologies and, significant movements of migration flows between regions [1]. Internationalization is becoming an increasingly important element of the political agenda of various governments. It is deemed to be a powerful factor that contributes to improving the quality and diversification of educational services, as well as sharing educational resources at the cross-border level. Thanks to the internationalization and integration of education, partner countries have stared developing joint education programs in which all leading global study centers take an active part today.

According to the OECD Education at a Glance 2019 report, the number of international students of higher education programs all over the world has grown significantly over the past few decades: from 2 million in 1998 to 5.3 million in 2017. In OECD countries, there were 3.7 million foreign students in 2017, which is 6% more than in 2016.

Foreign students account for only 3% of the total number of students enrolled in short-term higher education programs, and 4% of the total number of students enrolled in undergraduate programs, but they only account for 22% of the total number of students enrolled in doctoral programs [2, p. 229]

In addition, the Office of High Commissioner for Human Rights (OHCHR) points out that today we are observing the global transfer of population—65.3 million people are forced to leave their homes due to warfare, persecution or natural disasters. And if earlier the movement was carried out mostly within the region, now the flows of students and immigrants are interregional. That said, there are no legal instruments that would regulate the recognition of transnational education and qualifications both upon arrival of students and migrants in the country, and upon returning to their home country [3].

2 Materials and Method

The following scientific methods and approaches were used in the course of the research: historical method, descriptive method, comparative method, system-wide approach. The system-wide approach made it possible to comprehensively examine the subject of research, to study its components and their interrelations. The historical method provided an analysis of the transformation of regional conventions on the recognition and the development trends of the Global Convention on the Recognition of Higher Education qualifications. Descriptive method was used to review the underlying principles of the Convention, as well as its key differences from regional conventions. The chronological framework of the research covers the beginning of the twenty-first century, in particular, the period from 2012 to 2019, which is associated with the implementation of the Global Convention project, as well as the international mass migratory movement.

3 Results

The idea of creating a legal instrument that would focus on regulation of the recognition of academic qualifications crossing the borders of various states for their holders to obtain the right to continue to receive a degree in higher education abroad, was announced as early as in the early years of UNESCO. At the initial stage, this issue was mainly resolved at the regional level. As a result, 6 regional conventions were developed and signed under the guidance of UNESCO in the period of 70–80 s; they covered almost all countries of the world:

- Regional Convention on the Recognition of Studies, Diplomas and Degrees in Higher Education in the States of Latin America and the Caribbean (signed in 1974 in Mexico City, took effect in 1975);
- Global Convention on the Recognition of Studies, Diplomas and Degrees in Higher Education in the Arab States and the European States of the Mediterranean (signed in 1976 in Nice, took effect in 1978);
- onvention on the Recognition of Studies, Diplomas and Degrees in Higher Education in the Arab States (signed in 1976 in Paris, took effect in 1991);
- Convention on the Recognition of Studies, Diplomas and Degrees in Higher Education in the European States (signed in 1979 in Paris, took effect in 1982);
- Regional Convention on the Recognition of Studies, Certificates, Diplomas, Degrees and other Documents Certifying a Higher Education in the African States (signed in 1981 in Nairobi, took effect in 1983);
- Regional Convention on the Recognition of Studies, Diplomas and Degrees in Higher Education in the States of Asia and the Pacific (signed in 1983 in Bangkok, took effect in 1985).

Given the global trends in education, as well as the unprecedented scale of both voluntary and forced migration, many conventions on the recognition that had been adopted earlier required revision with a view to reforming educational systems, improving information support, the process of the recognition and the quality assurance of education.

It is worth noting that the revision and updating of regional conventions are not prerequisites for the development of the Global Convention. These two processes run in parallel. However, all regions had to make efforts in order for regional conventions to become the basis for the implementation of the Global Convention.

The common goal of the Global Convention is to serve as a uniform international legal act for all member states. It is able to regulate the practical recognition of higher education qualifications awarded by various service providers, by the Parties.

In 2012, the UNESCO Secretariat began exploring the implementability of a project to prepare of the Global Convention on the Recognition that would unite all parts of the world. The 38th session of the UNESCO General Conference made decision to present the "rough draft text of the Convention" in November 2017. To that end, the Editorial Board responsible for the preparation of draft convention, was established in March 2016, which included representatives of 6 continents and 23 countries [4, p. 67].

The Editorial Board held four meetings during the period of 2016–2017 during which a rough draft text of the Global Convention on the Recognition of Higher Education qualifications was developed which consolidated the comments and suggestions of all countries. The decisions of the 39th session of the UNESCO General Conference (November 2017) indicate that, in order to facilitate the people-to-people exchange and mobility of knowledge, teachers, researchers, training and students, UNESCO will continue to facilitate the follow-up revision and enforcement of six regional regulatory documents on the recognition of higher education qualifications and points of credit, including those obtained by refugees and displaced persons within the framework of the inclusive education system [5, p. 63].

In 2018–2019, several rounds of intergovernmental consultations took place in order to complete work on the text of the document, which required the interaction and joint effort of a large number of participants in the process to agree on key positions and solve the topical issues. At a meeting held in March 2019, the project was approved by more than 280 technical and legal experts from 150 UNESCO member states. Following consultations, the Global Convention on the Recognition of Higher Education qualifications, was officially adopted on November 14, 2019 at the UNESCO 40th General Conference.

The very fact of UNESCO's anouncement of the initiative for the creation of the Global Convention and the active start of work on its implementation indicates that the global academic community, whose interests are most fully represented by UNESCO, considers the institution of recognition as the most important factor in international educational and humanitarian cooperation and seeks to contribute to increasing its significance and efficiency [6, p. 92].

The key differences of the Global Convention lie in the presence of special terms in it that have been given inadequate attention in regional conventions. In the course of its

development, a glossary of definitions was created, which is aimed at reflecting new dynamics of lifelong education systems. In additon, this Convention also includes elements of the quality assurance of prejob training through the use of unconventional approaches and the recognition of cross-border qualifications, including the recognition of international joint degrees.

The Convention is based on the following principles:

- recognition of education as a fundamental human right. According to experts, the recognition of training and qualification at all levels of education should be deemed as a key element of the right to education. The implementation of the Global Convention will help achieve this goal by facilitating students' access to educational services outside their home country, enhancing efficiency of systems of the national quality assurance, promoting academic activity.
- respect for a wide variety of national higher education systems and academic self-sufficiency. The right of access to a fair assessment of qualifications has become the fundamental principle of the Global Convention. However, the diversity of national education systems and the right of higher educational institutions to make independent decisions on the recognition should be respected, thereby protecting their academic and educational autonomy.
- trust and ethics in recognition practices. The success of recognition practices depends on the level of trust between educational systems. Development, distribution and exchange of guidelines, instructions and principles of best practices in the field of international and interregional recognition practices must become a reference starting point of the Global Convention as an instrument of enforcement of trust and mutual understanding.
- the right to appeal and not to be discriminated against. The applicant is inherently the most vulnerable party to the recognition process, so it is important to pay close attention to enforcement of his rights. If there were no conventions on the recognition that ensure the rights, the applicant could be easily refused even without passing the stage of his/her qualification assessment.
- educational policy in the field of economic, structural and social reforms. Development of higher education through the promotion of international mobility will contribute to economic, technological and social changes all over the world [1].
- recognition of the incomplete education of refugees and displaced persons and their general certificates of education. Each member state within the scope of its education system and in accordance with its constitutional, legislative and regulatory provisions shall take all necessary and possible measures to develop optimal procedures designed to provide a fair and efficient assessment of whether refugees and displaced persons fall under the relevant requirements regarding access to higher education, continued education under the higher education programs or searching for employment opportunities, including cases where incomplete/former education or general certificates of education issued by another country, cannot be duly documented [7, p. 9].

4 Conclusion

The current refugee situation, being the gravest since the Second World War, forces students to seek opportunities for study in other countries, even if they are not able to provide the already available diplomas and other documents certifying a higher education. In this regard, their chances to receive lifelong education and employment are greatly reduced. If the global percentage of students of higher educational establishments is 36% (which is 2% higher than that in 2017), then for refugees this figure has not increased and is still 1%, despite a significant increase in absolute figures achieved through investment in scholarship programs and other programs [8, p.12].

Governments of various countries should take necessary measures to ensure that interruptions of education of refugees are kept to a minimum. Exceptional circumstances, such as the physical isolation of refugee communities or the limited nature of potential of the host education system, may impede all-round coverage.

At the same time, in order to achieve the successful implementation of the Global Convention that would meet modern needs of cross-border mobility, there will be an inevitable need for the use of elements of more developed systems for the recognition of higher education qualifications in certain regions, in particular, Common Higher Education Area. First of all, it concerns managing the system for the recognition of higher education qualifications, as well as a network of national information centers as the core of the cross-border information exchange, accessibility of reliable information, and decision-making transparency. Moreover, any systems of the cross-border recognition of qualifications are invalid without including mechanisms for the quality assurance of education in them in the member states on the uniform terms.

The adoption of the Global Convention by the countries will result in the increasing degree of openness of education systems and reducing barriers to academic mobility all over the world, as well as improving information support by creating a global information network, the process of the recognition and quality assurance of education. It will serve as a perfect model in ensuring the right of applicants to a fair and non-discriminatory assessment of their higher education qualifications by competent national authorities. It will allow strengthening international cooperation in higher education and the trust to various education systems and their quality assurance mechanisms in accordance with the relevant sustainable development goals of the United Nations Organization.

In the meantime, it is disturbing that it may take a long time for a document of such magnitude to enter into force. In this regard, close collaboration between UNESCO and all stakeholders is necessary for the promotion of the Global Convention project in various countries and the formation of a favorable environment for the accession to it at some future day both at the national and regional levels.

Actual Problems of Using Digital Technologies in Russian Higher Education

Natalia V. Kazantseva, Ksenia N. Sergeeva, and Nadezhda A. Demina

Abstract The article deals with the introduction of digital technologies in such an important social sphere of the economy as education. The purpose of the research is to analyze the prospects for their use as a result of changes in the need for a new type of specialists for the digital economy. It is proved that a radical and abrupt rejection of traditional methods of education as a source of knowledge in the next few years is hardly possible, since it is necessary to create economic, legal, social, material, and psychological foundations for their implementation. This will be largely due to the academic mobility of teachers and students, changes in the labor market, increased technical support for the educational process, and other processes. The research methodology consists in using system approach, cause-and-effect, economic-statistical, abstract-logical, and comparative analysis. The informational basis of the study in the framework of this article is the legal acts on the digital economy, statistical data, and electronic resources. The problems of introducing certain digitalization tools into the higher education system are identified however, based on resources, a generalizing conclusion is made that they are not dominant and do not eliminate the existing traditions of classical University education, while at the same time providing a more dynamic development of the educational services market. Estimates of the prospects for applying certain elements of digitalization in domestic education are presented. Recommendations are given for building models of interaction between the state, business, scientific and educational institutions, ensuring the availability of new quality educational services. The authors also proposed the basics of the conceptual model of digitalization of an educational institution, including new technologies, artificial intelligence in educational and scientific activities, marketing

JEL Classification I20 · O10 · O30

1 Introduction

The development of the scientific and educational sphere, innovation and technology is the key to economic growth in almost any country. Updating the production base, improving technologies and the rational distribution of funds between scientific research are all components of increasing the competitiveness of both individual enterprises, industries and industries, and the state economy as a whole [14].

The digital environment contributes to the formation of new approaches in the development of educational services that are currently referred to as digital transformation, digital leadership and others. These issues are addressed by scholars of various countries. Western researchers addressed them more than a quarter century ago. These authors include Bell, D., Weber, F., Bode, D., Mahmut, F., Riis, A., Bond [15], M., Toffler, A., Hanamari, H. et al.

As for the Russian authors, they have addressed this issue quite recently. Indeed, along with the concept of "digital leadership" another concept—"digital inequality"—emerged, and domestic authors could not ignore these processes. These authors include Dneprovskaia [1], Yenkov and Yershova [2], Ivanov, V. N., Meshcheryakov, R. V., Strygin, A. V., Serafimovich, I. V., Shamsutdinova, T. M., Engovatova, A. A. and many others.

However, such research typically deals with only certain positive or negative aspects of the use of digital technologies in various business processes, or in a certain area of economic activity. They have been studied either poorly or insufficiently comprehensively in higher education. Moreover, in the framework of modern research, the competitiveness of universities and other educational and scientific organizations has been understudied. It is especially difficult to determine their competitiveness, except by creating a list of efficient and inefficient organizations according to formal criteria. Currently higher educational establishments are facing the need for the rapid transformation of the learning activity through the use of digital products and solutions, which involves the implementation of relevant measures to ensure a positive experience in the use of information and communication technologies. Furthermore, apart from the benefits of development of the digital economy, the risks should also be taken into account, which include the impact on the labor market and the degree of involvement of digital literacy of the population, economic inequality, health condition.

2 Methodology

The paper is aimed at developing proposals for the improvement of the process of digitization of higher educational establishments.

The paper highlights the problems of the use of digital technologies in higher education, suggests ways of solving them at various hierarchical levels of management and inside of a higher educational establishment as such. It is noted that standard methods cannot be used for assessing their performance in the digital economy; various strategies for their development (competition, growth, breakthrough development) suggest different principles of the assessment methodology.

Research tasks were solved through the use of scientific generalization and systemization; critical and logical and content-related analysis for the assessment of digital transformation of higher education in order to achieve its strategic goals. The authors of the work used modern methods of collecting and processing source information, factual data on the processes of educational activities of Russian universities. The authors' ideas are based on the analysis of scholarly works, the existing management practices of Russian higher educational establishments and the generalization of foreign practices of organizing university activities using the principal provisions of innovative and strategic management, economic policy.

3 Results

The result of the research is the conclusion about the ways of transformation of Russian organizations engaged in educational activities. Strategic changes in the organization of science and higher education management initiated by the Government of the Russian Federation indicate the need for transformations not only in the structure of educational environment and not only using administrative methods, but also increasing its flexibility and creation of adaptation mechanisms to bring it nearer and make it accessible to consumers, and, eventually, to the labor market [3]. This means that we must consider the fact that the introduction of digital technologies in the educational process is not only a progress but also a source of many problems in distinct areas associated with restructuring of higher educational establishments, including maintaining the identity of collegiate schools of sciences, the quality assurance of education and research activities, preserving the prestige of education and others. The main scientific result of this research consists in the theoretical justification of the impact of the innovation activity of a higher educational establishment in the field of digitization on its competitiveness.

As a consequence, the authors identified the following aspects of digitization of Russian universities.

1. Wlaborating a digital development strategy. The appearance of research universities in Russia contributed to the formation of their strategy of competitiveness and research superiority in the market of scientific and educational services,

including the worldwide market. These higher educational establishments are usually located in big cities or large regional centers.

The second group of higher educational institutions can be described as integrators of theoretical and practical knowledge and skills for certain economic spheres, sectors or territories. Although they are of federal importance, most often their research and filling the labor market stay within large territories.

The third group of higher educational institutions focuses on local labor markets and their research activity is purely applied in nature, being limited to solutions for enterprises in a particular region.

The latest trend is the development of regional higher educational establishments; hence, their preparedness for the introduction of digital technologies in education and research should be a priority. A higher educational establishment should focus on the needs of the external environment, restructure the in-house educational and business network, choosing the commitment to educational activities with a wide or narrow set of disciplines, or conducting research, forming an innovative ecosystem, including the interaction of the university with enterprises, other universities and scientific institutions with a view to creating competitive educational products (or solutions) and conducting popular scientific research [4]. As a result, the university needs to adapt to the environment and create an appropriate structure which helps to implement these processes, as well as to develop a corresponding strategy with the distribution of tasks, duties, resources and responsibility for achievement of results. If there are several higher educational establishments of various orientation, it is possible to create an educational cluster meeting various needs for the formation of the digital economy in the region. A similar experience can be found in Novosibirsk, St. Petersburg, and on Russky Island in the Far East. To solve these tasks, we need the support of government authorities at all levels, including federal and regional, as well as business requests. In this case, business and universities share risks, costs and competencies as partners in the interests of intensification, improve their status, becoming better known among consumers.

2. Continued possibilities and preparedness of Russian higher education for introducing digital technologies in its activities. (Dneprovskaya 2019; Tulchinskiy 2018). Here, it is necessary to take into account not only economic aspects assuming the formation of portfolio investment taking into account all possible investment sources, including equity funds, funds of state budgets, local budgets, and sponsorship donations.

Information and communication technologies are pervasive in all sectors of economy, which promoted such concept as digital economy. These processes are being introduced in the economy of higher educational establishments. Digitization of economic processes is the transfer of business processes previously that had previously been carried out by people and organizations to the digital environment in order to improve performance results [5].

Table 1 The contribution of the digital economy to the GDP of the Russian Federation in %

Russian Federation	Share of GDP	Household spending in the digital sphere	Investment in digitization by companies	Government spending on digitization	Exports of computer and information technologies	Imports of computer and information technologies
2018	3.9	2.8	2.8	1.2	0.7	−1.8
2019	4.3	5.1	3.8	1.5	1.0	−1.7

Compiled on the basis of [13]

When we analyze the global market of digital technologies, it is necessary to identify its key parameters, namely financial indicators and the contribution of the digital economy in domestic gross product and the average annual rate of market growth (Table 1).

Having identified the prospects for development of the digital economy, including those for education, the authors noted that in the context of informatization it is necessary to make provision for the cooperation of all actors involved in the learning and innovation processes of the use and creation of electronic educational resources; it is they who become the development basis for various learning technologies. This is a real increase in the qualitative results of educational and innovative activities of higher educational establishments, expressed in specific digital products and solutions, and, ultimately, in the creation of a competitive innovative product. We should also mention the fact that investment in any technologies and innovations most often have a long shot, and apparent results will be obtained after an indefinite time, when the investment will leave an imprint in many areas of the organization's activity [14].

One of the tasks of a modern Russian university is to informatize its activities, including the educational process. The very paradigm of education is changing. In traditional higher education, experience, conservation of traditions, and formation of schools of sciences constitute the core of the educational process. The dominant role of a leader in the context of digitization is changing, the hierarchy of relations is being transformed in the teaching staff. The supervisor can no longer fully define the development objectives; he directs development and monitors the development of new digital technologies and determines which technological innovations are currently not only feasible, but also suited for a university.

The climate of integration of higher educational establishments in the digital economy begs the burning question of digital literacy of higher-education teaching personnel and administrative personnel that are defined by a set of knowledge, abilities, and skills, and allow creating and distributing digital programs and solutions, organizing interaction, developing and introducing new ideas and solutions, solving problem situations, ensuring more efficient use of digital technologies and web resources. The knowledge of professionals of a new breed includes the basics of working in an age of uncertainty, project management, entrepreneurship, marketing, programming, Artificial Intelligence, robotics, and prudent provision of services. As for the skills, they must include multiculturality, multilinguality, client-centeredness,

artistic creativity, management skills, which means that digital thinking of participants in the educational process in higher educational establishments will evolve in the direction of cognitive, behavioral and emotional transformation [6]. As a matter of fact, state-of-the-art information technologies are a fine alternative to the classical learning model.

The priority project "Modern digital educational environment" involves the creation of a system of training and further training of teachers to the use of digital technologies in online education. For example, plans call for training 10 thousand teachers for online education only in this program in 2020.

3. The need to improve the organizational, financial, technological and content-related components of the educational process. In recent research, these processes are construed as the creation of an ecosystem of a higher educational establishment, electronic information and educational environment of a higher educational establishment as its digital infrastructure [7]. There are various aspects of the formation of electronic educational environment of a higher educational establishment, such as administrative-and-managerial and interactive. Most people still perceive learning as formal education in a higher educational establishment [8].

Continuous and everyday interaction with other people and with the world around allows acquiring knowledge without a reference to a specific place and time, whether it is an educational institution or a place of employment, where knowledge gained is applied. This time, educational environment is perceived in another context, the practice of using electronic educational environment is based on a radically new quality of communication and on the iteration of all participants.

4. The formation of a smart education system in a higher educational establishment. It is aligned with the previous problem, because it's smart education that will ensure adaptation to changing environment that is much-needed for modern higher education, response to external changes, achieving goals, self-development and self-assessment of all participants in the educational process, especially students [9]. They are given the opportunity to use various smart devices in the realization and organization of the educational process with the use of specifications of e-learning, cloud computing technologies, distance distributed learning, access to global educational content, creation of flexible educational technologies coupled with practice-oriented learning [10].
5. Modelling of digitization processes of higher educational establishments. This problem requires development of conceptual framework of a model which includes certain stages, that, based on the capabilities of a higher educational establishment, can be implemented either simultaneously or gradually [11].

At each stage, a higher educational establishment chooses a priority stage in accordance with the developed development strategy and the features of an educational institution [12].

Based on the foregoing, the authors put forward the following model of university digitization, which includes the harmonious development of internal elements

of a university, building effective interaction with the external environment, using the concept of marketing relations and marketing communications. Accordingly, the main elements of the model of digitization of higher educational establishments (Fig. 1) are as follows: novel technologies and the use of artificial intelligence in educational and scientific activities, partners, digital interaction inside a higher educational establishment, digital marketing, and competitive research projects.

The authors have identified the following essential requirements for the assurance of digitization of the university and its competitiveness in the current context:

existence of leading scientific schools;

- an actually operating system of incentives both for individual employees (higher-education teaching personnel, educational, research and auxiliary personnel) and a system of motivation in the interaction between different units;
- innovation activity both by individual employees and the entire organization. That is, the structure of this organization must be flexible and innovatively receptive;

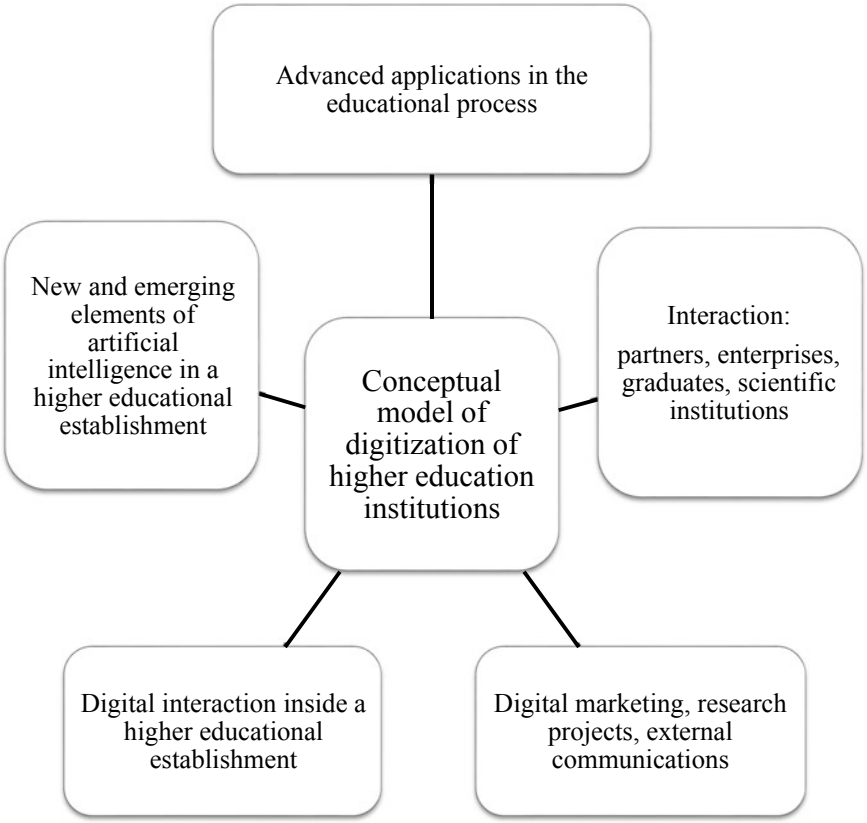

Fig. 1 Conceptual model of digitization of a higher education institution

- forming-up effective interaction with external partners in the matter of creating competitive educational programs and popular results of intellectual activity, including the actual digital products and solutions.

4 Conclusions

The conclusion outlines the main scientific results of the research, reflecting the directions in which the process of formation of digital strategies of a higher educational establishment can be built. The national policy in the field of formation of the education space should be based on the needs of the national economy, ensuring that the labor market is filled with the necessary professionals. At the same time, personnel must be provided for the breakthrough fields of the economy, regional human capacity, and access to quality education for the majority of citizens. Solving these tasks, which include provision of personnel for the digital economy, largely depends on higher educational establishments themselves. With this aim in view, they will have to solve a number of tasks in order to achieve this goal and eliminate the existing problems by implementing one or more strategies.

The authors of this paper have offered the following ways of digitization of universities.

1. During the first stage, higher educational establishments should assess their capabilities and preparedness for the introduction of digital technologies in all spheres of their activities. And this means not only availability of computing capacity and telecommunications; this means reshaping the entire organizational culture of a higher educational establishment, changing the roles of supervisors and each team member from the perspective of digital leadership, developing new knowledge and skills.
2. The solution to the following problem, namely, the creation of an electronic information education environment, will require solving a whole range of tasks, including organizational, financial, technological and content-related components of the educational process. This will not only enable access to external content, but will also facilitate the development and delivery of online content to the students.
3. Preparedness of students for the introduction of digital technologies, on the one hand, should be more smooth due to their almost 100% preparedness for using gadgets and for technological innovations. On the other hand, their education in the smart education system should be guided by specially trained teachers (Ershova 2019).
4. The digitization of academic education is a complex process, it occurs in Russia nonuniformly and at a rather slow rate. This matter should be approached from a strategic perspective, justifying all stages of modelling in an integrated manner.

Restarting the Education Model in the Digital Economy

Alla A. Kanke, Natalia I. Morozova, and Viktoriya I. Tinyakova

Abstract The primary resource of a post-industrial knowledge-based society is the creativity of a personality, his/her ability to generate new knowledge and information, which directly depend on the quality of training of skilled professionals. It is education that forms the human capacity of highly educated professionals; without it, any innovative nature of development of the economy is out of the question. A dynamic model of economic development should correspond to an adaptive education system that promptly responds to the demands on the labor market and is able to reproduce in-demand professionals for the future. Solving this problem requires new educational process implementation mechanisms, a new universal set of competencies that will not depend on the trade that is learned and will make it possible for a future professional to quickly adapt to changes in the environment. In order to maintain its large share in the educational market, traditional education will need to undergo a transformation at the level of forms aimed at developing authenticity, reducing teaching to its original form, endowing it with its original content and tenor. Gamification of learning has the potential to become an efficient tool for the modernization of learning that gives a boost to self-development. Even today, we are witnessing how rapidly the market for educational gaming environments is growing; hence, it will be able to become an actual competitor to the traditional education system in the near future. As a result, educational institutions will be forced to include interesting and educational-functional gaming tools in the educational process. The authors substantiate their idea that IT technologies are able to give new momentum to the development of inclusive education, which makes it possible to ensure professional self-fulfillment for people with disabilities, give them the opportunity to feel themselves as productive members of society, to be needed in the professional area.

1 Introduction

The twenty-first century is an era of rapid changes and challenges facing humanity due to the new industrial revolution, which is based on the digitization of various fields of activity. Even today, technologies such as "smart energy", "smart appliances", "smart enterprise", "smart homes", "smart cities", "smart information and analytics", "smart medicine", "safe city", e-government and many others, are becoming familiar [1–3].

Traditional value chains, in which a number of steps should be made for the transformation of resources into products: design, planning, production and sale, are rapidly collapsing. They are succeeded by additive manufacturing or 3D printing technologies, which can be used to develop and manufacture complex products without intermediaries, without large warehouse inventory and with minimum transportation costs. A new economic order is beginning to take shape, which is based on processing an array of big data, augmented reality technologies, the Internet of Things, and so forth.

Companies are starting to compete with digital platforms, and a small group of gifted enthusiasts are often enough to create a fast-growing industry [4, 5]; The Platform Revolution: How Network Markets Change the Economy—and How to Make Them Work for You, [6].

A new economy and a new technological mode pose challenges to mankind that can only be solved by a person with certain knowledge and competencies [7]. Educational level becomes the key success factor of a person, the main productive power of society. It is professional skills of a person and his ability to learn throughout life make him highly sought in the labor market. This, in turn, promotes further development of the economy, its transition to the innovative model of functioning. [8, 9]. Provision of finance for education will create conditions for the emergence of innovation enterprises in various economic spheres, which will create a stable foundation for the formation of the digital economy. In other words, education creates opportunities for further development of the economy, and requests of the economy determine the vector of changes in the education system (Fig. 1).

Hence, a new education model is required, that would take into account the needs of fast-paced environment and train professionals with a definite set of competences, sought-after in the labor market, and capable of expanding the scope of their professional activities as necessary. In other words, the current task of education should not

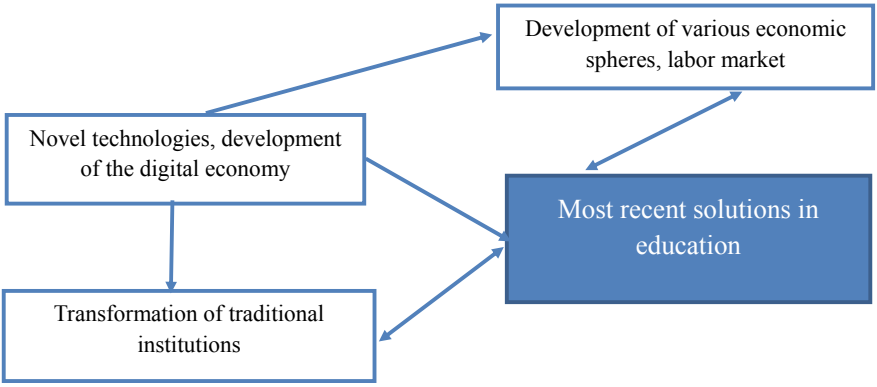

Fig. 1 Model of mutual interaction of the digital economy and the education system

be simply to teach a person, but to teach him to learn, search for new knowledge and independently master it. The innovation-driven economy can only be built through this approach.

In order to tackle the challenge of modern economics, education should restructure its traditional methodological approaches and technologies, build a new form of relationship with the labor market aimed at developing personal educational and career paths highly sought by employers.

2 Background and Methodology

The author's concept was formed through the analysis of the basic ideas of the features of formation and development of the digital economy that were presented by such scholars as Beckert, J., Bringeofsson E., Cohen, J., Coleman, E., Coyle, D., Kekhin, B., Leidner, D., Mclean, E., Tapskott, D., Terranova, T., Samuelson, P., Fung, K., Hu, I., Hooves, U., Scholz T. et al.

Real-world examples and the analysis of successful digital transformations presented in papers of such domestic and foreign scholars as B. Benlien, B. Bloching, F. Wisbeck, T. Hess, A. Dobrynin, V. Kupriyanovskiy, P. Leutiger, C. Matt, D. Namiot, T. Oltmanns, Remayn, G., Rossbach, S., Salle, J, Siniagov, S. A., Schlick, T., Schwier, D., Shefreniuk, O. et al. were of interest for the formation of the author's concept.

Certain aspects of improving the quality and efficiency of training of future professionals are presented in the works by the following Russian scholars specializing in various areas of knowledge: Adler, Y. L., Baydenko, V. I., Vasil'yev, V. I., Griaznova, A. G., Koriachko, V. P., Lukashenko, M. A., Romashkova, O. N., Telnov, Y. F., Shadrikov, V. D., Choporov, O. N. et al. Their research laid a foundation for the

development of a fundamentally new approach to the learning process in the digital economy.

The need for the application of a competency-based approach in the course of training of future professionals and for efficient human resources management was argued in the works by Russian and foreign scholars, in particular, Baidenko, V. I., Vialova, E. V., Zvonnikov, V. I., Zimniaya, I. A., Muraev, S. A., Spenser, L. M., Spenser, S. M., Subetto, A. I., Whiddett, S. Hollyforde, S. et al. Reliance on these research papers enabled authors to elaborate their own concept of transformation of the competency-based approach in the digital economy.

Unfortunately, however, the works of the above authors have not yet sufficiently covered the new outlines and educational process implementation mechanisms in the context of the ubiquitous digitalization of the economic domain. A new universal set of digital competencies that will not depend on the trade has learned not been formalized yet.

3 Discussion and Results

The actualization of the available set of competencies, the need for the search of new, never-before-seen competencies, increasing the importance of a man as the main productive power of society in a dynamic environment is conducive to the need for the emergence of new educational practices.

Unfortunately, the traditional education system is often not ready to update academic programs and to be a translator of modern knowledge and competencies due to enormous and constantly updating flow of information. It is not infrequent that information can become obsolete within a few hours; of course, it's a kind of analogy. Nevertheless, it is possible in high technology. A modern student, equipped with all kinds of gadgets, is able to quickly obtain the necessary information on the Internet, and a teacher who adheres to an approved curriculum with the use of traditional forms and instruments of transfer knowledge, loses his competitive edge.

As a result, there is growing tension and dissatisfaction over the existing education system among students and entrepreneurship. This leads to the need to look for new models of "interpenetration and interaction" of entrepreneurship and education, the use of novel methodological approaches, forms and technologies in education [10]. A teacher and learning technologies used by the teacher must focus not only on learning and transfer of knowledge, but also on the promotion of further development of a student. In other words, teach how to learn. The teacher in his work looks more like a "reflective practitioner" than a functional performer who has certain experience in teaching and practical activities. It should be a person who aspires to creative and experimental activity, is able to quickly adapt to ever-changing requirements of society [11]. In other words, the teacher must constantly inculcate in the student a love of learning, develop his ability to find the necessary knowledge independently, and develop an interest in scientific research. It is this approach that will make it

possible for a student to finish the formation of the necessary competency profile in the future [11].

Gamification of learning has the potential to become an efficient tool for the modernization of learning that gives a boost to self-development. Even today, we are witnessing how rapidly the market for educational gaming environments is growing; hence, it will be able to become an actual competitor to the traditional education system in the near future. As a result, educational institutions will be forced to include interesting and educational-functional gaming tools in the educational process.

The main advantages of gaming techniques are the development of teamwork, creativity, and overcoming template thinking. This will make it possible to "repack" important activities from the opening of one's private business to scientific research in the game. This problem is successfully solved by numerous simulation and virtual games, the main goal of which is to develop abilities and skills that are necessary for professional activity, cooperative effort etc.

For education, "first-hand" learning in the form of transfer of practical knowledge is also important. This results in the involvement of representatives of the business community who have up-to-date knowledge and practical skills in their field owing to their experience.

A student also begins to be proactive and to search for alternative opportunities of acquiring the sought-after competences in the labor market. This results in an increase in the number of students-autodidacts who are willing to present their own feedback for the purchased educational service. They are ready to independently formulate their learning goals and a package of knowledge and skills required for their professional development. The lack of necessary competences and the need to search for new knowledge forces such student to apply to the crowd school, where a particular exchange of knowledge and skills takes place. The atmosphere of creativity and joint search for necessary competences leads to the emergence of leaders who can compete with the teachers of traditional educational establishments.

The increased demand for authenticity becomes increasingly widespread social phenomenon. An increasing number of students are confused by searching for their own path of professional and career development, aiming to maximize their creative potential. Public educational resources are beginning to appear as a response to this challenge (MOOC platforms, such as as Oursera, edX, Open Education, Universarium, etc.), providing a range of services in the field of formation of a personal educational path and using proprietary methodologies for assessment of competencies gained [12].

The model of interpenetration and interaction of an individual, the business community and the education system in the digital economy is shown in Fig. 2.

In order to maintain its large share in the educational market, traditional education will need to undergo a transformation at the level of forms aimed at developing authenticity, reducing teaching to its original form, endowing it with its original content and tenor. The individual approach to education, face-to-face communication between the teacher and the students—all of this was lost as society moved to the industrial development stage. The main goal of education, just as the production, currently consists in massive scale and versatility. The experience of private tuition

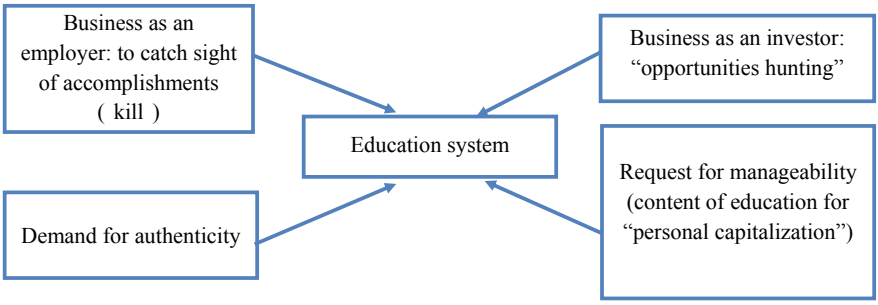

Fig. 2 The model of interpenetration and interaction of an individual, the business community and the education system in the digital economy

was lost. Today, when we are witnessing a transition to the post-industrial development stage, when IT technologies are increasingly becoming part of our lives; we can try to bring back the lost culture of individual interaction. Novel technologies are able not only to ensure customized approach to the educational process, but also to preserve its massive scale due to ubiquitous presence and availability.

Society and business environment are increasingly understanding that when a graduate has higher education, they cannot be sure they acquired the skills and competencies that employers expect from them. It is not infrequent that a graduate demonstrates their knowledge, but they often lack the necessary skills to apply this knowledge gained in practical activity. From this perspective, we should ask ourselves—what can be regarded as the result of the educational process? Such a universal unit of measurement may be manifested not in the qualification documented in the diploma, but in the acquired set of competences, which is individual in nature, and assesses the student's ability to solve professional cases [13–15].

Such competency-based approach will come up with the response to the question of who will be able to achieve success in the labor market: a student with a large bundle of knowledge, only able to transfer it, or a professional who has the required skills to transform knowledge and skills into goods and services highly sought by society. The educational process does not end with a university degree. There are also many professional cases at the workplace that need to be addressed every hour. Thus, the boundaries of the education space are expanding. A man needs to learn throughout his life; in this regard, we should talk not just about an educational path of development, but about an educational and career path of development. To substantiate this thesis, we shall emphasize that education lays a certain foundation for professional activity, and the career indicates what additional competencies should be obtained in order to successfully build it. The individual competency profile that was formed during the learning process in a higher educational establishment will then be updated and completed throughout human life as a person moves up the career ladder or changes his interests in professional activity. In other words, the learning process becomes permanent and accompanies a man throughout life.

The idea of changing educational concepts was announced at the UNESCO Forum by the major theorician J. Delors and aroused strong interest [16].

A new approach in education is becoming increasingly standard for leading economies and a development vector for developing countries. The new educational process implementation mechanism enables formation of the innovative economy and improvement of the quality of life of the population.

Information technologies, ubiquitous automation, and computerization are reforming the traditional employment structure; new professions emerge, and traditional professions pass away. There is a shift in emphasis towards the rapid development of the service sector in the economy [17–20]. People who are ready for changes, mobile, flexible and creative, become more sought-after in the labor market. This is another argument for the concept of "lifelong learning".

What is more, IT technologies are able to give new momentum to the development of inclusive education, which makes it possible to ensure professional self-fulfillment for people with disabilities, give them the opportunity to feel themselves as productive members of society, able to participate in the production process, be needed in the professional area, become economically independent.

The general view of re-structured education model is shown in Fig. 3.

The restructured educational process should become more oriented on the need of gaining practical skills and solving professional cases.

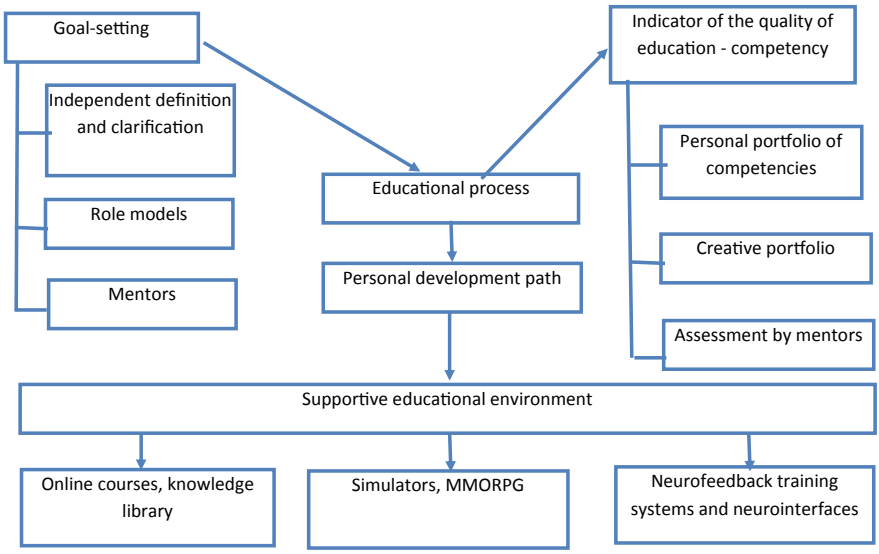

Fig. 3 Re-structured education model in the digital economy

4 Conclusions

The education system, aimed at training universal professionals capable of successfully conveying the acquired knowledge, which has been existing since the Industrial Age, does not pay off in a new environment of rapid development of digital technologies and formation of knowledge-based economy. The traditional education system needs restructuring. A new model of the educational process should allow for the multiple-vector existence of a student in the education space; respond flexibly and sometimes even anticipate the needs of a dynamic environment; pave the way for the professional growth of individuals with disabilities.

The "upside down" university could become a new educational model. Theoretical studies at such an "upside-down university" take place through the agency of leading MOOC platforms, mainly through the use of video lectures, and the students hone their practical skills in an educational institution in the course of lively discussion. Traditional lectures are completely replaced by video lectures, which allows reducing the teaching load of educators and gives students more freedom. On the other hand, this requires students to be more committed and independent.

This educational model will enable future professionals to acquire the necessary practical skills to successfully solve their job tasks and develop their career.

Improving Competitiveness of Personnel in the Digital Economy

Zhanna M. Korzovatykh, Nadezhda G. Morozova, and Hoang Thi Lan Ang

Abstract The Program "Digital Economy of the Russian Federation" that is currently being implemented by the government should contribute to the formation of an economic environment that would ensure the most effective interaction between citizens, the scientific community, business and the State, through the development of digital technologies. In addition to developing a specific statutory regulation system, the interaction of actors in the digital economy requires the training of relevant personnel with certain competencies: professional competencies that are required for the development and implementation of digital technologies, and user-specific competencies that are required for the efficient application of potential of information and communication technologies. The goal of this research is to identify relevant competencies that are transforming as a result of digitization of the economy and focused on improving competitiveness of personnel. General scientific methods of cognition serve as the basis for the methodology of the paper. These include observation, generalization, comparison, methods of analytical study of the content of regulatory acts. The digitization process has long been implemented in accounting through the use of various software programs and automated accounting systems that document business processes and are used to automate accounting and draw up financial accounting statements, so the introduction of studying the practical aspects of using software products in the educational process can provide graduates with skills related to the fundamental "digital literacy" of the users. However, in order to improve the competitiveness of personnel in the labor market in the digital economy, consideration must also be given to professional digital skills relating to mastering the digital technologies. That having been said, a set of advanced digital

competencies that a professional should have is no longer constant. Under the influence of the digital environment competencies become variable; they evolve into "dynamic portfolios". If this occurs, the business will focus not on personnel, but on the total "portfolio of competencies" of professionals which is formed depending on the business development strategy. The paper has developed a portfolio of digital competencies of modern personnel which in the authors' opinion must be possessed by professionals to improve their competitiveness in the labor market.

Keywords Automated accounting systems · Digital economy · Digitization of accounting · Digital competencies

JEL Classification I25 · O10

1 Introduction

Over some recent years, digital technologies that have been widely used recently, have been exerting direct influence on the development of the country's economy and significant changes in people's lives. Artificial Intelligence, Internet of Things, wireless communication technologies, and robotics have been widely used both in business and in the social sphere. Modern digital technologies have a significant impact on the development of all sectors of the economy, becoming an integral part of modern management systems. In next to no time, efficient use of digital technologies will determine the competitiveness of not only companies and their personnel, but also of individual countries, establishing the infrastructure and legal framework for the digital economy.

The comprehension of the fact that future in general belongs to digital technologies and actors that create, introduce, develop and use these technologies, is increasingly growing. Digitization of the economy involves the development of areas of investment in IT technologies and personnel training in order to create the latest technological solutions and achieve compliance with contemporary trends and requirements of the markets.

Digital economy is a basis for the creation of a brand-new business model, and, accordingly, it changes the format of education and communications, forming new lines of social development.

The development of digital technologies implies an increase in the quantity, quality and variety of interrelations between companies and citizens associated with the emergence of new types of transactions that require professionals to have competencies that are focused on working with state-of-the-art information technologies. The existing practical interaction of economic actors establishes relevant requirements to the development of a statutory regulation system and the formation of new personnel competencies.

Thus, one of the key factors in the development of digital technologies is the availability of highly-qualified personnel with certain competencies: professional competencies that are required for the development and implementation of digital technologies, and user-specific competencies that are required for the efficient application of potential of information and communication technologies.

2 Background and Methodology

Digital economy as a new socio-economic phenomenon which is developing at such a rapid pace that economic theory is lagging far behind in the study of this phenomenon. Currently, the term "Digital Economy" is regarded by theoricians and practicians as widely different phenomena and processes; therefore, the basic methodological principles that underlie the research are based on the points of view of Russian and foreign scholars studying digital technologies.

The theory of research is based on the works of contemporary scholars and practitioners in the digital economy. Theoretical research deal with the formation of provisions in higher education, focus on training of professionals in new professions, having such professional competencies which imply their propensity for unconventional creative thinking and contribute to the development of communication skills. It is the education system that determines the efficiency of transition to the digital era which is characterized by new employment relations.

General scientific methods of cognition serve as the basis for the methodology of the paper. These include observation, generalization, comparison, methods of analytical study of the content of regulatory acts in the digital economy. A differentiated examination of the results of the analysis of the use of software of automated accounting systems in enterprise activity has been used as the main methodological principle of the research.

Data from the Federal State Statistics Service of the Russian Federation, provisions of the National Program "Digital Economy of the Russian Federation" and other institutional regulators were used for the justification of authors' provisions.

3 Discussion and Results

Currently higher education institutions have been set the task of solving the personnel problem; these institutions are to develop education programs for training of specialists that would conform to contemporary requirements and be competitive in the labor market in the context of digitization, since the employers will give preference to "digitally literate" professionals in the near future [2].

Today, among the uses of digital technologies in organizations, the greatest demand is for those that make it possible to automate banking and financial transactions (Fig. 1).

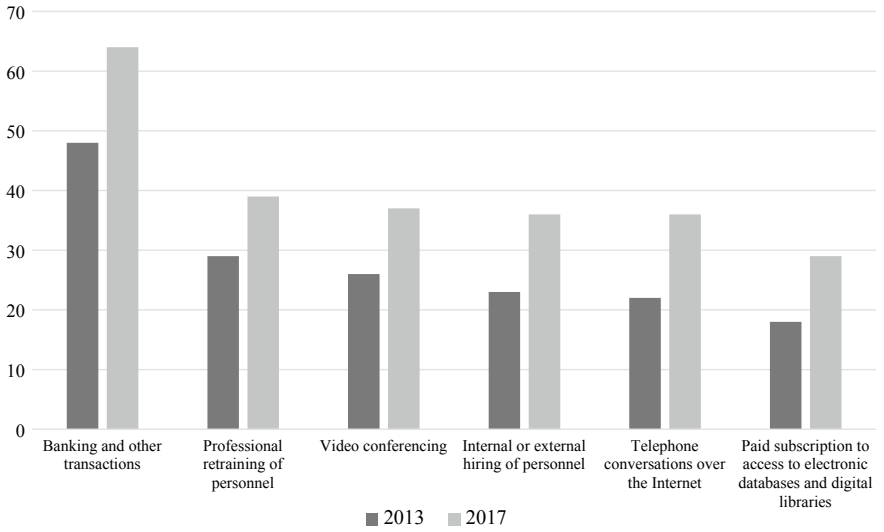

Fig. 1 Uses of digital technologies in organizations (in % of the total number of organizations). Compiled by the authors on the basis of [1]

Ensuring the training of highly-qualified personnel for the digital economy has been identified as one of the top priorities of the Project "Personnel for the digital economy", which is aimed at achieving training of 400,000 people a year by 2021 within the scope of the vocational education system with key competencies in the digital economy, and this indicator should reach 800,000 graduates a year by 2024; that having been said, special focus is on the graduates of IT specialties [6, 7]. If Russian higher educational establishments currently train about 50,000 of IT professionals a year, then this indicator is expected to increase to 120,000 professionals a year by 2024. Moreover, the emphasis is not on basic education but on additional and professional retraining, since the digital economy is dynamic and developing at a rapid pace, which in turn steps up the requirements for the knowledge and skills of professionals (Fig. 2).

The independent implementation of academic programs of professional improvement and growth of employees has become available to the business since the development of digital technologies, which makes it possible to take into account specific needs and guarantee conformity of training of personnel to the needs of a particular enterprise [11]. Employees, in turn, gain skills and abilities, perform their job duties in a more qualitative manner, significantly increasing and expanding the level of their functionality in accordance with the goals and objectives of the enterprise. Investment in personnel training and development contributes to the development of reputation of an enterprise as an innovative and socially oriented one, as well as the growth of its attractiveness as an employer.

Digitization calls for permanent development of education, which implies permanent education throughout life of a person starting from preschool, secondary, higher

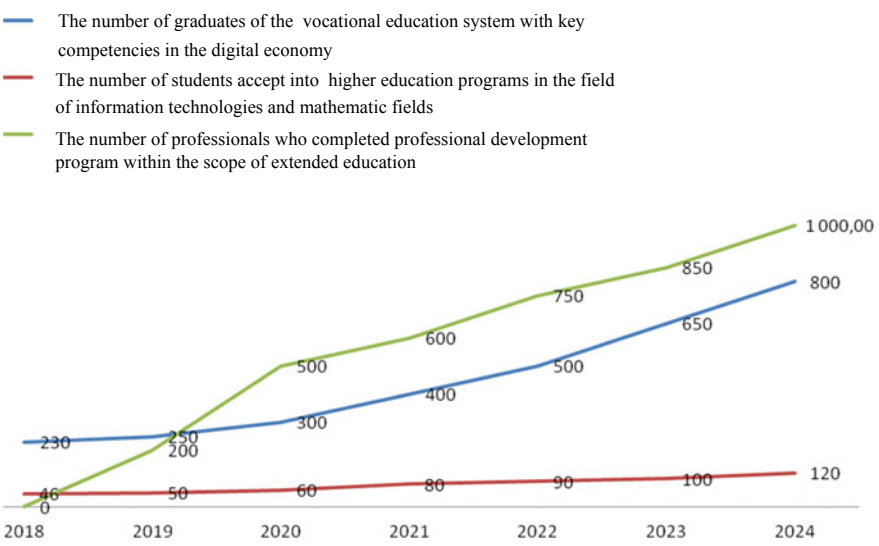

Fig. 2 Indicators of federal project "Personnel for the digital economy", 1000 people. Compiled by the authors on the basis of [7]

and extended education and ending with systematic postgraduate studies of trained specialists with the possibility of attestation of skill level in the corresponding qualification assessment centers within the framework of the emerging national system of qualifications in the country [3].

It is obvious that the issues of personnel training in accordance with the tightened requirements and aggravated competition become increasingly important in the digital economy. The key driver of global educational trends is the introduction of artificial intelligence systems [14], which stimulate the further development of a growing online education market in turn [15]. In Russia, this trend hasn't manifested yet.

Digitalization is being introduced in the accounting profession both in a broad sense and in a narrow sense. Digitization of accounting shall be generally understood as organizational and technological processes of the use of new digital technologies in the organization of accounting process, which helped relieve the accountant from the necessity to manually fill out primary documents, accounting registers and reporting, documentation of business transactions related to property accounting, sources of education and obligations on the business accounts, mathematical computation (computation of taxes and charges). Digitization of accounting makes it possible to quickly process data arrays; promptly present analytical information in a visual form (diagrams, graphs, and tables); instantly exchange information between departments, between the head and subordinates, contractors; quickly draw samples, generate consolidated returns; significantly reduce the number of paper media.

The key factors in the development of economic activity also include various data in the digital form, processing of large volumes of such data and the use of analysis results, contributing to the enhancement of efficiency of various businesses in general.

In a narrow sense, i.e. in technical terms, digitization in accounting means the transition from an analog form of processing and presenting information to a digital form, that is, based on the use of Internet technologies. Thus, communication with regulatory authorities, banks and counterparties is carried out through digitization.

Currently a prerequisite for a breakthrough in accounting methods is the development of blockchain technologies that use accounting registration systems and allow storing transaction records in a single register with cryptographic information protection and a secure distribution system. Further development of the accounting system moves towards formation of bases of financial indicators, and bases that characterize social, environmental and other nonfinancial indicators, meeting the criteria of authenticity of and provision of customization of user's interests [13].

Development of the digital economy provokes rapid emergence of an imbalance between personnel and technologies employed, contributes to the development of technological unemployment which requires knowledge of the scope of operations and appropriate information processing methods [8]. Digitization processes and their introduction into accounting entail the need to increase the competency of the respective accounting personnel and improve competition in the market. The pursuance of enhancing efficiency of business processes and digitization development will contribute to the subsequent transformation of professions in a new environment.

Digital economy will still need the profession of accountant, albeit assuming new context, where an accountant is a business partner who is able to assess various risks, think flexibly, continuously improve himself/herself and develop necessary competencies.

At the same time, technologies are considered as the main factor among the success factors of business events, which accounts for about 55% of success, while about 20% of success accounts for personnel. However, an appropriate balance of factors should be achieved [10].

A considerable number of papers deal with the issues of adaptation of accountant's profession to the digital economy environment. For example, Get'man, V. G. gave an estimate of the quality of professional education of students who chose the professions of accountant and auditor in national higher educational establishments, and offered a comprehensive set of measures that make it possible to bring the level of their professional education to requirements specified by the business more in line with professional skills; in particular, he pointed out that, in addition to fundamental accounting skills, graduates need knowledge and skills in the field of information technologies [5].

Soboleva, G.V., Popova, I.N., Terent'eva, T.O. also note that currently the vast majority of requirements for specialists who receive education in accounting involves the use of the latest technologies in the educational process and focuses on the

objective of giving students not only the knowledge that is actively required by the market in accounting today, but also the knowledge that will be needed in the long run [12].

The flow of information, which is received and independently generated by the organization in the course of its financial and economic activity, should be processed, analyzed and stored, which cannot be done without the automation of accounting and analytical systems. The digitization process has long been implemented in accounting through the use of various software programs and automated accounting systems that document business processes and are used to automate accounting and draw up financial accounting statements [9].

A fairly large number of software programs for automated accounting systems (AAS) are available in the modern Russian market; they are based on various accounting techniques and various types of ownership and activities used in organizations (Table 1).

The major purpose of the AAS under consideration is the automation of accounting functionality, that is, ensuring automatic presentation of business processes, operational efficiency, reliability and convenience of data storage and analysis.

When analyzing the practical application of the AAS by organizations, it has been found that the following software programs obtained the widest circulation among the software for the organization of accounting, management and tax accounting process: "1S", "Parus", "Galakitika" and "BEST". The main factors for their common usage include extended functionality, reliability and flexibility, compliance with existing legal standards and requirements, and regular updates [4].

Among the software programs that are most frequently used by the organizations of the Russian Federation, "1S" software, which is a set of software products, became the most widely used product, since it provides ample opportunities for customization, separate item-by-item revenue accounting and expenditure accounting, management and financial accounting in various accounting systems of the organizations, and activity-specific analytics; moreover, it is suitable for multiple types of accounting in one or several organizations of different fields of activity and forms of ownership.

Such automated accounting systems as Parus, BEST, and Info-Bukhgalter are less functional and much less common due to the special-purpose nature of accounting automation [4].

Therefore, it is expedient to introduce into the educational process the study of practical aspects of application of software products for the automation of business processes most commonly used by the organizations of the Russian Federation.

Digitalization of the economy toughens competitive confrontations for the right to possess the latest and commercially promising achievements.

Competitiveness will depend on the timely creation of an appropriate intellectual potential and community of promising specialists with new competencies. At the same time, the human factor, which is at the same time a key resource for economic growth and competitiveness, is a constraining limitation.

The introduction into the educational process of studying the practical aspects of the using of software products can provide graduates with skills related to basic user "digital literacy", therefore, it's necessary to pay attention to professional digital

Table 1 Automated accounting systems that are used in the practical activity of organizations of the Russian Federation

AAS	Characteristics of software and hardware of automated accounting systems	
Software for the organization of accounting, management and tax accounting		
Name	Advantages	Disadvantages
1S	• automation of various accounting segments; • versatility; • generation of consolidated returns for in-house needs and controlling bodies; • regular updates of software versions; • promptness of updates of databases and reporting forms	Poorly integratable • costly
Parus	• usage by small and medium organizations of various sectors of the economy; • flexibility, high performance and wide functionality; • operation on one or more machines of the local network	• deferred updates
BEST	• functional separatedness by application units; • user-friendly and simple interface; • wide variety of teaching materials	• deferred updates; • closeness of the system
Info-Bukhgalter	• prompt preparation of standard and regulated reporting; • assessment of financial and operational performance;	• deferred updates
Galaktika	• ability to work with multiple charts of accounts at the same time; • maintaining of records in accordance with international standards; • promptness of updates of databases and reporting forms; • making the necessary calculations; • forming and filling all kinds of tax and accounting documents	• lack of problem-solving algorithms; • no control over implementation of a number of operations; • not integratable

Table 1 (continued)

AAS	Characteristics of software and hardware of automated accounting systems
Client Bank	• remote banking transactions; • real-time supervision of settlement accounts
Financial analysis software	
Vash Finansovyi Analitik, FinEkAnaliz	• financial analysis of the organizations at a specific date; • business development forecasts based on the analysis
Automation of internal control system	
EkspressAudit: PROF	• control over compliance with legislation in accounting and taxation
AuditNET InternalAudit	• administration of the internal audit service
Software programs used for interaction with tax authorities	
ASK NDS-2	• transfer of data on economic events, primary documents (invoices), and VAT tax returns to tax authorities
Online cash desks and specialized programs for transferring information to the Federal Tax Service	• transfer of the information on settlements of accounts to tax authorities via the fiscal data operators

skills related to mastering digital technologies. At the same time, the set of advanced digital competencies that a specialist should possess ceases to be static.

At the same time, competencies are a continuously accumulated intellectual capital formed through the implementation of modern and effective educational policies. Possessing the necessary competencies, provided to compliance with general trends, will make effective decisions.

Under the influence of the digital environment and the transformation of professions, competencies become volatile, turning into "dynamic portfolios". In this situation, the companies will focus not on the staff, but on the total "portfolio of competencies" of specialists, which is formed according to certain strategies of the company. Thus, the digital economy, based on digital technologies, creates a demand for specialists who own a "portfolio of digital competencies" (Fig. 3).

The current stage of development of society in the context of the digitalization of the economy is based on the using of a larger amount of information, innovation and the latest technologies, and also person, his knowledge and skills that indicates the need to master the competencies of the digitalization century, which form the digital career history of a specialist.

Of course, the transformation of the profession of accountant and the requirements for it undergo regular changes and the observed processes are quite objective and caused by the acquisition of new qualitative characteristics, attributable to the changes occurring under the influence of the information technologies and the expansion of the digitization area which should be particularly stressed during the learning process of future professionals.

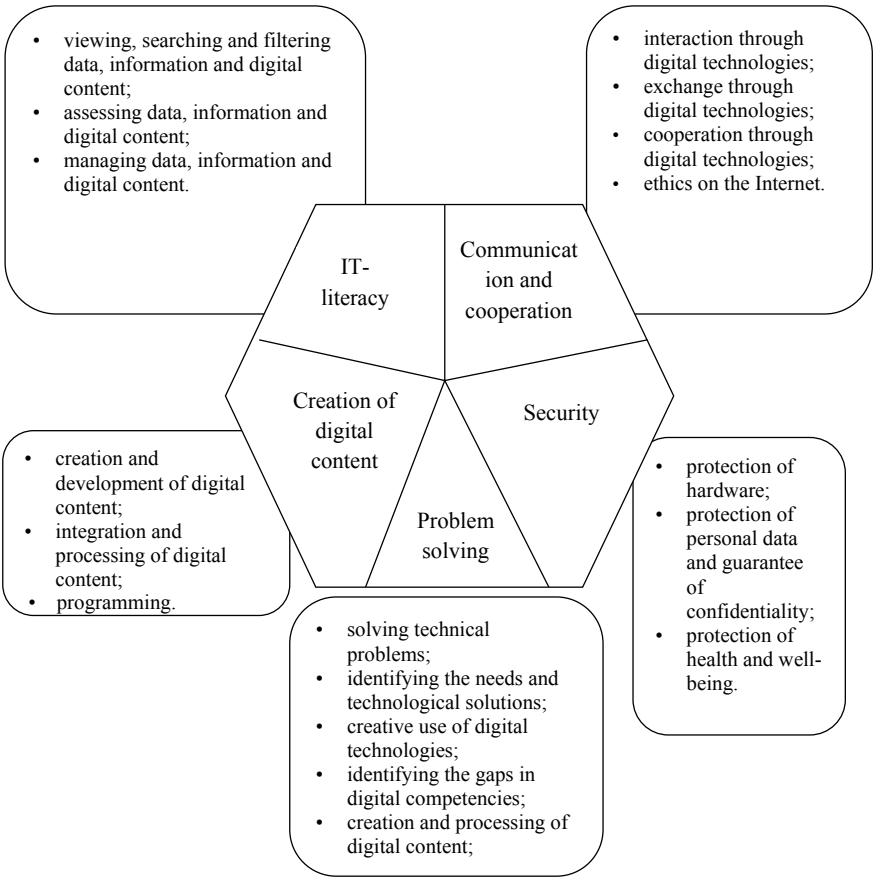

Fig. 3 Portfolio of digital competencies

At the same time, the transformation of educational processes in the preparation of accounting personnel, in order to increase their competitiveness, should occur in the following key positions:

(a) The implementation of the concept of lifelong education using modern educational technologies, implying the professional development of a person throughout his life, including mastery of new competencies.
(b) Fortification the digital infrastructure of the educational space, ensuring appropriate conditions by equipping them with appropriate technical devices and programs.
(c) Implementation of educational programs, applied in practice, of accounting programs and software products that can provide skills from basic user "digital literacy" to professional digital skills related to mastering digital technologies.
(d) Ensuring the appropriate qualifications of the faculty, allowing the using of digital technologies in educational processes.

(e) The formation of a business community in the framework of the educational process, providing training in popular promising areas and specialties.
(f) The flexibility of educational programs that can adapt and adapt to changing market conditions and trends, implying the formation of a portfolio of new digital competencies, such as: IT literacy, communication and cooperation, digital content creation, security and problem solving.

4 Conclusions

Digitization processes in the economy necessitate the transformation of its statutory regulation systems, business processes, education, and the formation of new personnel competencies. The education system determines the efficiency of transition to the digital era and support of the business with highly-qualified personnel, sought-after and competitive on the labor market, as well as meeting the requirements of the business to their professional skills.

The education system should focus on training professionals with certain competencies: user-specific competencies that are required for the efficient application of potential of information and communication technologies as well as professional competencies that are required for the development and implementation of digital technologies, such as: IT-literacy, communication and cooperation, creation of digital content, provision of security, and problem solving.

Lexical Units Objectifying the Intercultural Concept in "Babur-Nameh"

Gulipa A. Madmarova, Syuita R. Abdykadyrova, Rakhat K. Ormokeeva, Ikibal A. Temirkulova, and Rakhat Zh. Sagyndykova

Abstract Identification of common lexical elements with the definition of specific linguistic foundations and the drawing of language parallels that objectify an intercultural concept based on the vocabulary of the work "Babur-nameh".

At the center of modern language science is a person; language is studied in direct connection with its' native speaker, focused on a certain cultural potential, a representative of a national community.

The problem of methodology of research of linguocultural concepts in modern science of language seems to be sufficiently developed. At the same time, the question of methods of analysis of intercultural concepts remains open today. This is largely due to the ambiguity of the nature of the intercultural concept and such accompanying entities as the literary text, the national picture of the world, etc. On the one hand, many intercultural concepts appear as a kind of cultural concept with a similar name, which received representation in the literary text.

The term "concept" is one of the relatively new concepts that have appeared in the terminology of modern Russian linguistics over the past 15–20 years. This is a "borderline" term, it is in the spheres of use of several Sciences: cognitive linguistics, linguoculturology, linguoculturology adjoins close disciplines-ethnolinguistics,

psycholinguistics, sociolinguistics. In foreign linguistics, the term "concept" has been used before. In Russian, the word "concept" is translated as "notion", and "concept" is a tracing paper from the Latin word "conceptus".

The language reflects the structure of people's lives, it contributes to the formation of national character. The study of this problem goes back to W. von Humboldt, who spoke about the national specifics of the language, which he called "the spirit of the nation." He also created the active-energy concept of language, which is organically included in the modern philosophy of culture, philosophy of language and anthropology. "Studies of linguo-cultural direction (works of A. Vezhbitskaya, V. V. Vorobyov and others) point to the productivity of Humboldt's position on the national character of thinking and its dependence on language, as well as the thesis that national features of thinking are closely linked and intertwined with universal regardless of the specific language" (Thorik 2000: 204).

Language contains its own national identity system, which determines the world-view of the speakers of the language and forms their picture of the world. Speaking about the fact that, mastering other languages, a person expands the "range of human existence", Humboldt meant precisely the comprehension with the help of language, through the "linguistic worldview", the picture of the world of another people [1–6].

Modern cultural, historical, political situation contributes to the study of foreign languages. Today there is every opportunity for languages to be studied "in indissoluble unity with the world and culture of the peoples who speak these languages" (Ter-Minasova 2000: 28).

The analysis of the text, the principles of which are established in linguistics, allows to reveal the linguistic, visual side of the concept. But the mental, semantic part of the concept is often not amenable to purely linguistic methods of analysis. For help, linguistics can turn to such a direction as literary criticism, in which there are methods of interpretation, methods of working with clearly not expressed or hidden meanings. Only in this way concept as linguaitaliana, linguistic and cultural education can be presented in its entirety.

The use of regionalisms in a work of art is advantageous in communicative terms: each people of the considered region perceives them as their own language forms, and at the same time they do not cause difficulties in understanding the text for Russian-speaking readers.

The use of an intercultural concept in a work of art is advantageous in communicative terms: each people of the region under consideration perceives them as their own language forms, and at the same time they do not cause difficulties in understanding the text for Russian-speaking readers. "Babur-nameh" is of great interest to linguists. Being focused on revealing the essence of the Eastern mentality, it is inextricably linked with the personality of its Creator, the representative of the Turkic Nations, the author of the work. For Zahir al-DIN Babur, the question of national identity, the problem of self-identification, the search for his "I" and the chosen path of self-knowledge are of paramount importance.Despite the prevalence of the name "Babur-nameh", the author himself most likely had the intention to call his work " Vakai "(وقائع, waqaa'iᶜ" Events"), and the subsequent rulers of the Mughal Empire called it"Wāqiᶜāt-iBāburī—a Book in the Turkic language, written by His Majesty."

The iranized name Babur-nameh appears only later in the translations of the autobiography from the Chagatai original into Persian, in accordance with a widespread tradition at that time.

Highly gifted, versatile talented author gives an apt description of the political and administrative structure not only of his native Fergana, but also of other regions of Central Asia, pays no less attention to the description of nature, flora and fauna, gives toponymy and geographical description of the conquered areas and the etymology of many historical terms of the time.

Close contacts of native speakers of Turkic languages with native speakers of Indo-European, Mongolian, Tibeto-Chinese and Semitic languages, rooted in the distant past, numerous migrations, intensive processes of language interference are interesting material in the work. Babur's notes chronologically cover the events of the period 1494–1528. His notes are divided into three parts: "Fergana", "Kabul" and "Hindustan". Of them on the content of Mongolism you'll be the first part. This is largely due to the fact that Fergana was part of The Chagatai ulus, and the fact that the bulk of the Mughals of mogolistan in the early XV century moved to Fergana [1, p. 15, 16].

Mongolisms and historical terms in "Babur-name" can be divided into 5 groups. The first group can include the names of Mongolian clans and tribes (aimags). The notes mention the names of such Mongolian clans and aimags as jalair, Barlas, kauchin, orlat. Babur's notes repeatedly mention the names of people from the genus Cauchin: Ali MazidCauchin [1, p. 13, 14, 55], QasimBeyCauchin [1, p. 14, 16, 18], Mir Shah Cauchin [1, p. 40, 55] and others. The etymology of the word "cauchin" dates back to the Mongolian word "huuchin" (hauchin), which means "old, ancient".

The second group of Mongolism "Babur-nameh" includes the concepts and terms that the author believes the Mongolian. Here are some of them. The younger brother of Sultan Mahmud Khan and Sultan Ahmed Khan, the uncle of Babur, became famous under the name of Alach-Khan. On this occasion, the notes noted: "they Say that the reason why he was called Alacha, is that in the language of the Kalmaks and Mughals killer called "alachi", and since Sultan Ahmed Khan several times defeated the Kalmaks and exterminated many of their people, he was called alachi, from frequent use [the word alachi] turned into Alacha " [1, p. 11]. Babur writes that the word Karshi is a Mongolian word. According to him: ""Karshi" is a Mughal name, the cemetery in Mughal language will be Karshi.Probably, this name appeared after the conquest of [Transoxiana] Genghis Khan" [1, p. 47]. In the historiography of the Chagatai ulus it is believed that the word Karshi dates back to the Mongolian word harshi, which means Palace.

The third group of Mongolism in "Babur-nameh" include administrative, legal and military terms. In Babur's notes the terms *tuman* and *orchin* are widely used [1, p. 21, 49, 100–104].

The word fog comes from the numeral *tum*—10 thousand, i.e. darkness, and the term *orchin* means "district, around." Both terms refer to the military-administrative units of the Mongol Empire. During his lifetime, Genghis Khan divided the territories of the conquered countries and allocated allotments to his four sons. These destinies were called ulus. In the same meaning Babur uses this term: "Mughal ulus" [1,

p. 9, 10]," Kazakh ulus" [1, p. 12]. Uranium is a Mongolian term. According to Babur, each tribe has its own uranium and uranium is of two kinds. For example, one tribe uranium—"the madhouse", the other "tucky" or "Lulu".And "the second uranium-one for all army" [1, page 105]. Hence we can assume that one uranium was tribal, and the other—combined arms. In addition, during the war, uranium served as a password. According to Babur, "in the war Uranus establish two words: during the battle at the meeting, one person says one word, and the other says the second word, so that in this way to distinguish friends from enemies and recognize his from another" [1, p. 124].

Uranus is a Mongolian word meaning "forward, call" (Uriah, Uriah). According to the Russian researcher T. A. Bertagaev, uranium comes from the Mongolian word uragshaa, and hooray in medieval Mongols was tribal uranium [5, p. 175]. Nuker—a military squad of tribal nobility, which arose during the decomposition of tribal relations. "The duties of theNuker included military service to the Lord, the protection of the person of the Lord on the battlefields, … in peacetime, he served as a messenger, participated in the round-up hunt, took part in the Palace and on the farm" [7, p. 146]. The duties of the Nuker khans and noyons of Babur-name appear to have been identical, and according to Babur, the nukers were protected by their khans and noyons. In Chagatai language Aha, a: ka after a female name meant a Princess or a relative of the Khan [40, p. 60]. The given meaning is most likely from the Mongolian language. Ms. Mongolian AUA/agaa "lady", "lady", from where it entered the old Uzbek language.Borovkov in the" Vocabulary of Central Asian tefsir… "allocates the meaning of these words" older relative, sister or aunt " [34, p. 72].

In the names of flora and fauna in "Babur-nameh" there are terms that may have Mongolian roots. For example, Teke [1, p. 441]—Mong. teke-mountain goat, kulan [1, p. 142]—Mong. khulan-wild horse light suit, bute [1, sec. 140]—mong. booth—bush, the shrub;tabulgu [1, p. 15]—Mong. tavylha—tree species. Mongolian and Turkic languages belong to the same language family, so inevitably both languages have identical words with the same meaning. And to consider them Mongolian would be a mistake.

Arabic vocabulary occupies a significant place in "Babur-nameh". With many Turkic peoples, the Arabs had direct economic relations, and therefore borrowing occurred directly. Uighurs, Turkmens and Uzbeks had the closest contacts with the Arab world, as they adopted the Islamic religion before other Turks. Among the vocabulary of the text we find many arabisms: *azan, Allah, sherbet, harem, kasida, Emir, Sheikh, madrasah, mullah, etc.*

The Arabic word Mullah is mistakenly attributed by some linguists to the Turkic language. The lexeme in question is clearly of Arabic origin both in semantics and appearance.

The word Mullah comes from the arabic*mawla/mawla* "Lord, sovereign". Initially, this title was given only to high-ranking representatives of Islam, and later becomes the property of all educated people. Phonetically *mawla/mawla* changed in Turkic languages to *mollo/mulla/moldo*. Along with this, in some Turkic languages, for example, in Uzbek, there is another word related to the considered: *mavlyana/mayalana/mavlono*.[madmarova]

*Mavlono*east.mawlana, lit. «Our Lord» is the title of Muslim theologians and scholars, and the Mullah is a priest, a Muslim religious preacher. In the work under consideration, the Mullah is a religious servant, an interpreter of the Koran, who follows the provisions of the Sharia. He also had some judicial power: he could marry and divorce people, release them from the given word, etc.

Arabic vocabulary is firmly rooted in the Turkic languages. As can be seen from the "Babur-name", it refers not only to religious concepts, but also household items, plants, food, buildings, etc.The largest number of arabisms refers, of course, to religious themes: Sultan, Allah, Emir, Madras mosque, Rabat, Caliph, Sheikh, minaret, Mawlana, Gazelle, etc. due to the fact that during the events described in the work Islam occupied a leading place in the life of Muslims, it is quite understandable the high use of many Arabic lexemes in the text. The etymology of most of them is quite transparent and semantics, and the appearance of words.

In "Babur-name" there are the following iranisms: *bazaar, shah, caravan, dervish, kalandar, saray, dastarkhan, pilaf, etc.* Most borrowings are usually monosemantic, although there are exceptions. A striking example in this sense can serve as the word divan.

Divan in the sense of "sofa", "piece of furniture" currently has no Oriental correlation, but the other two meanings of the word are pronounced Oriental color.

Divan in the sense of "advice."*Divan* in the meaning of a collection of poems by any author.

In the text of "Babur-nameh" *khodja*—a title of some rich and noble lords from the environment Babur. It could be both spiritual and secular person. Title *khodja*most often was hereditary, although sometimes this word could to dissent and in the significance of the "Mr.", joining to behalf of as anthropoformant and denoting simply the rich human, even not the descendant the prophet. At present, this lexeme is not widely used in modern turkic languages. Basically it operates as part of proper names: Mirhodjaev, Isakhojaev, etc. less often-as a respectful address to an elderly person (*kozho* in kirg. language) [madmarova].

The lexical units objectifying the intercultural concept in the work "Babur-nameh" were formed under the direct influence of socio-historical, economic, cultural, religious and other factors and represent a complex system that emerged in the process of centuries-old historical development.

Most of these units continue to be used in modern Turkic and Mongolian languages, often with minor changes.

The development of material culture, socio-historical changes, economic and religious changes affect the vocabulary of languages. Over time, the words that came into use, go out of it, but the main ones remain unchanged, often only modified or take the basis of the Turkic or Mongolian versions. At all times, Turkic, Mongolian and any other peoples have had, have and will have terms denoting intercultural concepts. Such terms are often used, taking the rules of pronunciation and intonation of the language of the people by whom they are used, thereby preserving in everyday life quite ancient forms of vocabulary.

Digital Transformation of New Employee Adaptation Processes

Tatyana V. Suvalova, Rafik A. Ashurbekov, and Oleg S. Suvalov

Abstract The main purpose of the study is the analysis and identification of promising digital adaptation technologies, a synthesis of theoretical views and practical experience in this area. The article provides a theoretical analysis of the modern understanding of adaptation, emphasizes the relevance of a systematic approach, identifies the priority tasks of a mentor, substantiates the process of transition to automated technologies. The paper deals with the automated processes of optimization of adaptation of Yandex, Google, SKB Kontur, and IKEA. The analysis of current trends, opinions of experts of Forbes Coaches Council, PMG, data from Careerbuilder, Intermedia, Institute of Labor has been carried out. Positive results have been confirmed from the introduction of web-services, chat-bots or virtual assistants, video lectures and trainings, 3D office tours/excursions, which make it possible to acquaint the employee with personnel of the company, to satisfy his/her objectives more quickly. The introduction of automated services has significantly speeded up the productivity of new employees. The transformation of the views of senior management to the adaptation system is justified. Modern business leaders attribute adaptation to the strategic priority areas of personnel policy. Description is given of a future promising adaptation strategy that is recommended by the members of the Forbes Coaches Council. Special emphasis has been made on the focused acquaintance of new employees with corporate culture, the effectiveness of automated mentoring programs and online-training programs. The importance of the "First 90 days" approach has been justified. The efficiency of the automation of adaptation for personnel retention, reducing financial and time costs, improving efficiency of the employee from day one has been confirmed. The function of information security during the automation of these processes has been emphasized. Digitization

reduces the time needed to obtain, process, reconcile and transmit important data. A new employee not only gets acquainted with functions, but also learns faster, since he/she feels that he/she is a part of a virtual and real-world team. In an era of global digital transformation, it is important to find a system-wide approach which would combine human potential and IT potential.

1 Introduction

In an era of global digital transformation of business processes, a growing number of organizations start seeking to improve and revise their approaches to personnel adaptation. The range of fields of activities and personnel is expanded during the period of brisk growth and development of a company. And sooner or later, supervisors are finding that they cannot allow that much time and resources to adapting a new member of the team. Many processes are being optimized to achieve this goal: budgeting is being introduced, consumption of particular resources is being reviewed. Personnel and all the rest of it usually are the largest item of expenditure. A lot of effort and money is spent on search and adaptation of new employees, while a mistake may be very costly. Even if you find an excellent professional, but do not give due attention to his/her adaptation, you will have to repeat the search process which eventually results in losses.

The modern idea of adaptation is interpreted as a systematic process of familiarizing an individual with its subsequent integration into the organizational and social conditions of functioning, the development of interaction technologies, understanding of corporate principles, and organizational culture. A change in interests and a transformation of stereotypes of behavior of both parties are formed in the interaction of the individual and the collective. According to the Russian scientist Pavlov I.P., a correct understanding of the idea is an inexhaustible scientific topic for studying the essence of many phenomena. In the works of G. Isaac, the interpretation of adaptation is based on achieving harmony between the individual and the environment. Vesnin V. R. notes the importance of adapting a person to the social environment, identifying one's own interests with the tasks of the organization. Bazarov T. Yu. notes the transformation of personality behavior depending on the requirements. Groshev I.O. emphasizes the complex process of mutual adaptation of the individual and the company. Marchenko O. I. focuses on the temporal parameters of adaptation. Summarizing the ideas of researchers of the adaptation [1] system, its main goals can be distinguished: the formation of a positive attitude towards the company and the team, reducing the loss of time for performing production tasks, understanding the specifics of work, reducing the anxiety threshold.

Adaptation of staff is an important component of work. Unfortunately, many companies don't pay special attention to this process. There are still many organizations in which even the primary stages of adaptation are absent. But with the advent of foreign companies on the Russian market, the trend towards the development of an adaptation system in domestic companies has increased significantly.

The process of hiring a new employee is a very long and costly process.

The new employees, who can work as long as possible and bring benefits, are very important for the company. But, despite this, a very large percentage of employees leave the company in the first three months of work. Based on the results of the exit interview, it often turns out that the reason for leaving is: unjustified expectations (they said one thing at the interview, but in reality everything turned out differently); the tasks for the trial period weren't clear; contact with the leader and the team didn't work out, each went about his own business and didn't come to the rescue. The priority task of the leader, mentor, team and HR manager is to maximize the individual's ability to integrate into the company in a short time.

Therefore, there is a need for the development of automation technologies for adaptation processes. Many companies use only basic elements of the adaptation process; for example, they hold a welcome training, introductive courses and a lecture aimed at induction, or present a welcome-book. In an environment of ubiquitous digitization, there is a need to move to the automation of adaptation processes through the use of sophisticated technologies.

One way or another, personnel adaptation is a two-way interaction: on the one hand, a new employee gets acquainted with the company; on the other hand, the behavior of an employee changes due to requirements and rules imposed by corporate culture.

2 Methodology

This research is aimed at identifying advanced digital technologies of personnel adaptation processes, improving the performance of personnel and reducing the term for it to yield the expected result.

The data obtained are based on the methods of theoretical analysis of domestic and foreign experts in the management of human resources; methods of system analysis and logical modeling of digital transformation of adaptation processes which were used as a basis for defining the basic concepts of research, its areas and findings. Empiric methods were used: observation, questionnaire, study of documentation; statistical and analytic methods with subsequent processing of findings obtained [2].

An analysis of the results of the Equifax study showed that retention by professionals is an urgent issue in many companies.

The improvement of adaptation technologies was based on recommendations for developing new adaptation strategies for the Forbes community of trainers [3], data analysis by CareerBuilder, Intermedia, and the Labor Institute.

The practical experience of restructuring the adaptation system of Yandex, Google, PMG, the SKB Kontur IT-company, and the IKEA-company is summarized. Distinctive characteristics of the analyzed companies are their stable growth, the emergence of new business areas and, accordingly, the growing needs for new staff. To solve this problem, the organizational adaptation process was as automated as possible. Optimization of a systematic approach to adaptation by digitalization is due to the fact that in the analyzed companies, even new employees are immediately immersed in the work on important projects.

3 Findings

A large number of companies are already involved in persistent efforts aimed at transforming their personnel adaptation processes through the use of digital technologies [1]. We shall give consideration to several specific examples.

For example, Yandex faced the problem of transformation of the adaptation system due to explosive corporate growth. This issue became particularly topical when recruitment increased to about 100 people per week. The human resources department faced the following tasks: increasing the number of personnel; emergence of new business areas; emergence of new managers. As a result, goals have also emerged: to build a well-organized process; to form a shared sense of culture and instruments; to increase the speed of getting into the way of things; avoid significant increase of the staff of HR department in solving the problem.

Prior to its transformation, Yandex adaptation system was as follows. The first working day included execution of documents; receipt of equipment; overview of the company and organizational issues. During three months of work: beginner's training; meeting with the adaptation manager.

As soon as certain processes are automated and chat bots are introduced, the adaptation system changed as follows. The first working day: automation of execution of documents; receipt of equipment; video overview of the company and organizational issues; welcome letter; handing in souvenirs. The second working day: a top manager talks about the company; a newcomer's introduction to services and technologies. The first working week: training in internal instruments; immersion map. First three months of work: immersion in the profession; office quest; interviews and meetings with the adaptation manager. These activities are held by five adaptation managers with the help of personnel department and customer support department with the participation of recruiters, HR partners and hiring executives (How do they work in Yandex, 2020).

SKB Kontur has already been actively using digitization methods in the adaptation system. SKB Kontur is an IT company involved in development of software and Web services for business. The company has 8,500 employees, 86 branches in 74 cities. The average increase in employees is 100 persons/month. Adaptation managers not only very carefully studied the issue of implementation of landing into the new employee adaptation process, but also into the implementation of this project. With

this in mind, they gathered a working group of those employees who are really interested in being involved in creating such a product. They conducted a series of interviews with new employees to identify their real needs. They took into account all possible user scenarios that may arise. They have selected the necessary tools and services that will help them in the implementation process. And they tested the results on the focus group.

The results of this project were as follows: 14,695 views over the year, of which 5874 were unique; the web page is visited not only by new employees, but also current employees; 86% of the interviewed newcomers rated the website at five out of five; the rate of company-wide adaptation has increased by 20% [4].

IKEA took things a step further and solved its problem of the adaptation of personnel of various ages. As is well known, IKEA's social policy is that they employ people of different ages, starting from 16; their eldest employee is 70. IKEA is guided by the following principle: successful adaptation of employees is always a system-wide approach. This is why they developed a new adaptation system for a particular age group of employees.

Corporate culture that supports diversity and inclusiveness: meetings, events and workshops with executives and employees; integrated business approach [5]. The ongoing leadership development for managers at all levels: the theme of the value of each person, various approaches to work, including work with people of different age in leadership training programs; the theme of diversity in internal auditing of personnel management processes [6]. The system of step-by-step training during the employee adaptation period: mentoring system in every department; adapted structure and content of the introductory training for new employees; the list of all necessary knowledge and skills for every position with useful references. Culture and the system of conversations with employees: mandatory short conversations between the employee and his/her immediate supervisor and mentor during the adaptation period; development of an individual growth plan that takes into account the "learning-by-doing" approach. Understanding the prospects of development and own contribution: approach to work with potential for all employees—opportunity to develop along the career ladder; approach to professional development—opportunity of long-term development deep into the profession; cascading the goals of the business plan: goals for executives are detailed to the goals for employees [7].

Moreover, many companies are already actively using such tool as chat-bot/virtual assistant in the new employee adaptation process [8]. This tool helps to respond to the newcomer's questions online, such as paydays and general information about salary, organization structure of the company, 3D office tour/excursion, information on how to take a vacation etc. Such chat bots often also use personnel interviews for interim attestation. This tool helps not only to improve involvement of a new employee in the adaptation process, but also to automate several processes which were previously performed by personnel manager. However, this method also has a downside. For all the convenience and modernity of chat bots, a very important component of socialization and adaptation of an employee in position and team—personal communication—is lost. We would like to point out that approach of reducing personal

interaction with the newcomer will be for by far not all companies; it is important to consider peculiarities of corporate culture.

When it comes to the adaptation process in foreign companies, Google is one perfect example of how it looks like. In one day before a new employee arrives, the supervisor receives a letter from HR, which describes five important steps in the newcomer's adaptation: to discuss his/her core responsibilities; to appoint a mentor and introduce him/her to the newcomer; to help the newcomer get acquainted with the team members and establish a contact with them; to document every success of a newcomer's adaptation on a monthly basis during the first six months after recruitment; to conduct an open dialogue. The letter is sent to each supervisor on an individual basis, so that they develop a sense of their own responsibility for adapting a new member of the team. This discreet innovation helped to develop a sense of urgency and responsibility among supervisors, which in turn improved Google's performance by 25%. Google learned to manage priorities in working relations while maintaining an informal environment that makes employees happier. Studies have shown that happy employees outperform their competitors by 20% and work 12% more efficiently. As a matter of fact, Google has increased its employees' satisfaction by 37% by introducing cultural initiatives of the company. During the adaptation process, Google supports personnel development by training its employees and introducing them into corporate culture. While many companies train their employees by making them immerse themselves into the task and learn on the job, Google may spend over two weeks on immersing new employees deep into culture and theory. Such an educational approach and rapid adaptation are essential, since even absolutely new employees start working upon strategic projects and key functions [9]. In Google, they give their new employees a snap course of what they need to know, and they give newcomers a chance to show their worth in a matter that is really important. Unlike other adaptation processes, Google uses the open-ended approach to culture and involvement in the company.

According to Equifax, more than half new employees quit during the first year of employment in the company. To counter this problem, more and more companies place emphasis on personnel retention, and it starts from the moment of adaptation.

The members of the Forbes Coaches Council (Karima Mariama-Artur, esquire, Dina Simon, Linda Foster, Stacy Faner, Mark S. Bubbit, Sharon Hall, Edith Pakuk) advised on how to describe new adaptation strategies that will be made active use of in the years to come. The new personnel adaptation strategy consists of seven stages.

(1) Well-targeted acquaintance of new employees with culture at the workplace. New employees are often not acquainted with corporate culture in a new company. Company executives have been increasingly making adaptation a strategic priority, since they have come to realize that it is important to give clear guidance on immersing in culture and on how to maximize the efficiency of a new employee in it. In addition, many rules and principles of a particular company are often based on policy and strategy and are not found in manuals for newcomers, so disputes on corporate culture and immersion will most likely become increasingly fierce for strengthening the adaptation process.

(2) Mentoring programs. Companies invest many resources in culture and training. The teams move in one direction, and it is necessary to comprehend at this point in time who will integrate a new person and how this integration will be performed in order not to reduce the overall speed and efficiency of work. A mentoring program should be created for that, in which new employees will have someone who will teach them and immerse them deep into corporate culture and rhythm of work.
(3) Monitoring during the probation period. A key factor in the successful adaptation is monitoring during the whole probation period in order to make sure that a new employee gets integrated with culture and receives support and training, which is required for his/her success in a new office.
(4) Clear goals and objectives. New employees are successful right away when they are provided with all they need to start working: clear goals and objectives, correct tools and equipment to achieve goals, honest and regular career reviews from supervisor and mentor, and sincere, consistent recognition of good work.
(5) Adaptation as the team sport. A growing number of companies are already using the "First 90 days" approach. From day 1 to day 90, a new employee examines every detail that affects their work, conformity of these details to corporate culture and mission of the organization. "First 90 days" is not an HR function. From colleagues to the CEO, many people will be responsible for ensuring that these first 90 days set positive attitudes and priorities in the work of a new employee.
(6) Mentor-buddy. Many companies are already appointing experienced employees responsible for on-boarding, work planning, adapting and presenting a new employee to his/her office colleagues. It is important to ask a mentor-buddy to communicate with a new employee on a weekly basis during the first month of employment to identify their needs, and to hold such conversations at least once a month for the first six months. It is the responsibility of the supervisor to allocate timing budget to the mentor-buddy so that his/her tasks were not affected while he/she is immersing a new employee in corporate culture.
(7) More external support. While organizations are more aware of the fact that adaptation is the marginal success factor in recruitment of a new employee, the overworked management team currently has less time than ever to judiciously integrate a new employee.

Experts expect companies to put more emphasis on external coaching/support in the coming years to help people start working as soon as possible [3].

Claire Wiggill, Vice President for Strategy and Business Development in PMG, explains advantages of the automation of related processes to the introduction of a new employee. The automation of the introduction process may help organizations increase the retention level and reduce costs. The first few days in a new job are crucial, since they set the tone for what should be expected from the employee-employer relationship. Getting used to a new role has always been a challenging task. Basic office materials—security identification card, phone, laptop—are not always readily available. More importantly, almost all new employees cannot be proactive

from day one. Once both sides agree that they suit one another, it is much easier to focus on retaining the existing employee rather than finding a new one. Nevertheless, lacking or nonexistent employee adaptation processes are primarily responsible for the turnover of personnel.

According to the Institute of Labor, 34% of turnover of personnel accounts for employees of the first-year of employment.

High turnover of personnel is detrimental not only to morale of the company, but also its revenue position.

According to Gallup's estimates, a mere thousand-year turnover costs $30.5 billion annually. Given that the millennials have overtaken Generation X as the largest generation of labor force, this cost will continue to rise.

4 Conclusions

The problem of personnel retention exacerbates due to the presence of many moving parts in personnel departments, which error prone manual commissioning processes are simply unable to support. And if your company disregards adaptation, you too probably leave your dismissal processes vulnerable to errors [10]. As HR reaches every corner of the business, automation technology, designed to relieve the pressure of routine HR tasks from managers, is a must.

Since departments throughout the enterprise aim for innovation through technology, it is time for a HR manager to consider how automation can improve the efficiency process. HR and IT can work together with a view to implementing automation solutions that make arrival and leave seamless for employees and managers [11].

The automation sets employees and managers for thriving. Although they do not see this, employees benefit from the automation before stepping across the threshold.

The use of this solution for the automation of processes guarantees that all that may be required by a new employee—from a computer and necessary software applications to email account and security identification card—will be ready before the moment of commencement of work [12]. From one data point and several initial clicks, the whole process is organized, and each department knows exactly what it should enter and when.

The knowledge of what to expect and when to expect it is priceless for new employees. When all departments are on the same page relating to requirements for the introduction, a new employee can see the organization with all its downsides. 45% of employees who have underwent the structured adaptation process, claim that they trust their organization more [13].

The automation helps improving implementation processes; in turn, optimized implementation processes ensure high performance and retention.

According to Careerbuilder, 42% of employees are more productive when they have access to proper implementation processes. Furthermore, when new employees are presented with a more elaborate adaptation process, one can avoid their frustration

caused by poorly defined official duties and insufficient training—which usually are the main harbingers of turnover of personnel.

The automation provides protection for the enterprise. When it comes to dismissal, automated processes allow personnel managers to quickly reset passwords and receive new security identification cards. According to statistics, employees do not always meet these expectations—according to Intermedia, 44% of corporate employees say they would copy confidential information from their former employer if the circumstances were appropriate.

1st Franklin Financial Corporation faced the challenge of recruiting 250 new employees annually. Having automated the process, the company connected Active Directory to the new hiring process; as a result, information about the admission of a new employee is processed later on the same day.

The automation of processes makes it possible to cut additional time expenditures on manual processes [14]. That said, the automation does not mean complete removal of the human factor from HR, since HR departments and managers will have more time to concentrate on soft skills and personnel development.

The automation is no longer a luxury and have become essential for companies that have to compete for talents and protect their enterprise.

When the HR Department interacts with the IT team, the foundation is laid for more efficient processes and, ultimately, a more harmonious employee-employer relationship.

Preparedness of Higher Education Institutions for the Digitization of the Educational Process

Elena A. Mitrofanova, Aleksandra E. Mitrofanova, and Gulnar Sh. Zhaxybayeva

Abstract At the modern stage of development of information technology, the most important aspect of efficiency of higher education in Russia is preparedness of the higher education system in general and professors at higher education institutions in particular for working with digital technologies. Research findings presented in this paper allow assessing such indicators as the level of digital literacy of university professors, their mastering of ICT competencies, as well as the level of development of the digital educational environment of Russian higher education institutions, including the degree of availability of digital equipment in higher education institutions, the use of educational software products and online education services, the degree of development of training and online education technologies. This research allows making several significant conclusions which are necessary for the development of the higher education system in Russia in the context of the digital economy and the development of necessary methodological tools for the comprehensive assessment of preparedness of higher education institutions for the introduction of digital education technologies and products.

1 Introduction

The processes of informatization, multimediazation and virtualization as successful trends in the development of education significantly changed characteristics of both the educational process as such and the educational space. Therefore, as a matter of fact, there are no ways of updating educational processes without taking into account the peculiarities and innovations determined by the abovementioned processes, and the efficiency of vocational education and training substantially draught depends on the degree of filling the educational process with digital technologies and products [8].

2 Methodology

Education digitization process, on the one hand, requires development of the digital educational environment—a complex of digital teaching aids, electronic learning resources, and on the other hand—modernization of the educational process which provides for teaching students how to work and live in a digital environment [14, 15].

In addition, digital literacy and competency of university professors and their preparedness for digitization of education [2, 6, 7] are the key condition for digitizing education.

Hence, the assessment of degree of preparedness of higher education institutions for the digitization of the educational process must take into account the totality of factors defining the efficiency of the digital transformation of higher education institutions and the education system in general.

3 Results

The analysis of factors of digitization of the educational process in the higher education system of the Russian Federation which is mainly based on statistics and monitoring data led to the following conclusions.

3.1 Level of Development of the Digital Educational Environment of Higher Education Institutions

(a) Degree of availability of digital equipment in higher education institutions

The computer infrastructure of Russian higher education institutions is slightly inferior to that of European universities. According to statistical data, there is an average of 1 computer per 4 students in Russian higher education institutions [5].

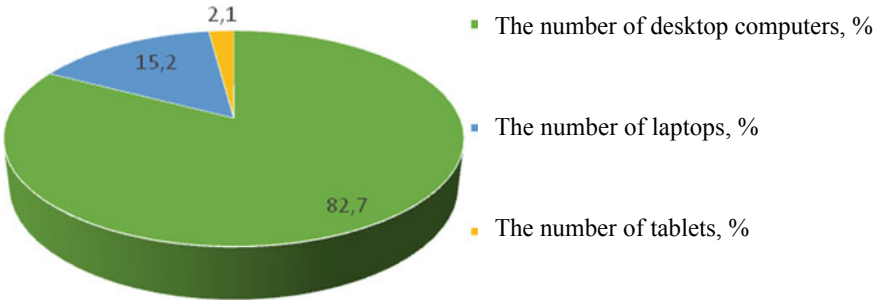

Fig. 1 Percentage of laptops and tablets in the total number of personal computers in higher education institutions (%), 2017 [18]

The number of handheld devices (laptops and tablets) is increasingly growing among personal computers (Fig. 1); multimedia projectors, interactive whiteboards, and other peripheral equipment (printers, scanners, multifunction devices) have been widely used.

A topical issue is the assessment of the quality of the university's Internet access. According to experts of the Higher School of Economics, the minimum Internet bandwidth necessary for the use of digital technologies and products should be at least 2 Mbps (the minimum Internet bandwidth abroad is 100 Mbps) [18].

According to educational system monitoring, the Internet bandwidth of 97.7% of Russian higher education institutions is 2 Mbps or lower.

Costs for digital technologies per higher education institution are 6.2 million rubles, a considerable part of which (62.3%) accounts for the purchase of personal computers, telecommunication equipment, servers, and payment for telecommunications services.

(b) The use of software in higher education institutions

In order to achieve the efficient use of digital technologies in the educational process in higher education institutions, it is necessary to use various software, such as electronic library systems, electronic versions of textbooks and teaching aids, training computer programs, digital reference books, encyclopedias, dictionaries, etc. [16].

The analysis of the use of software in higher education institutions is shown in Fig. 2.

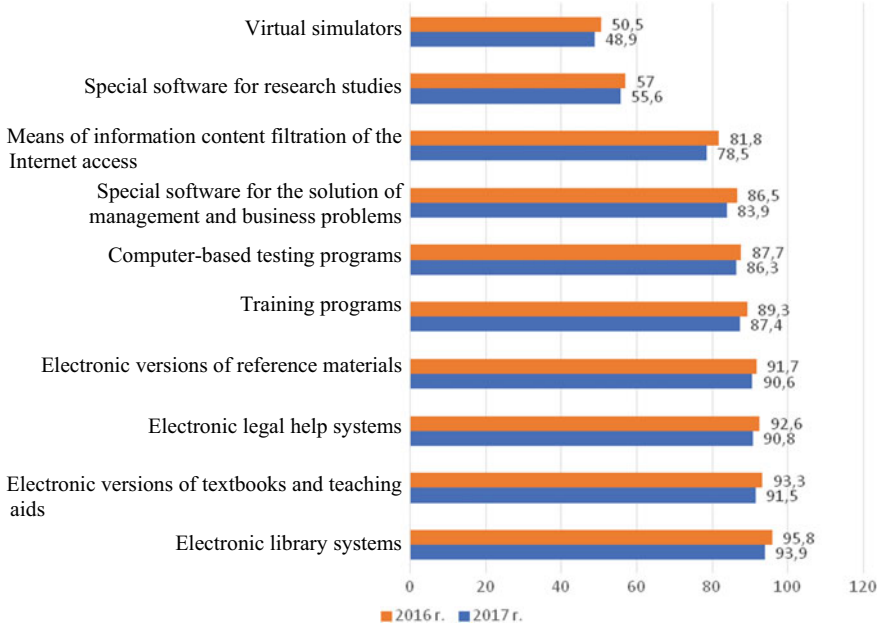

Fig. 2 The use of software in higher education institutions (as a percentage of the total number of higher education institutions; at the end of year) [1]

(c) The use of e-learning technologies

Digitization of higher education requires efficient use of e-learning technologies and online education technologies [19]. Today, the share of online education technologies in the Russian education system is very small compared to educational systems in developed countries; thus, e-learning and distance education technologies are only used in one in three higher education institutions [18].

The analysis has shown that blended learning is mostly used in national universities, while e-learning and distance education technologies are used for the information support of learning of students directly in a higher education institution [18].

That said, most auditors of education programs that are implemented exclusively with the use of e-learning technologies, study in national universities, while online education technologies are mainly used in nonstate universities.

(d) The use of online education services

Another stage of digitization of higher education institutions involves emergence and development of online education services, and, primarily, publicly accessible open online courses MOOC (Massive Open Online Courses) [4, 9].

Analysis of statistics has shown that the number of available courses of MOOC is steadily growing, but the scope of their use in higher education is still quite moderate (Fig. 3).

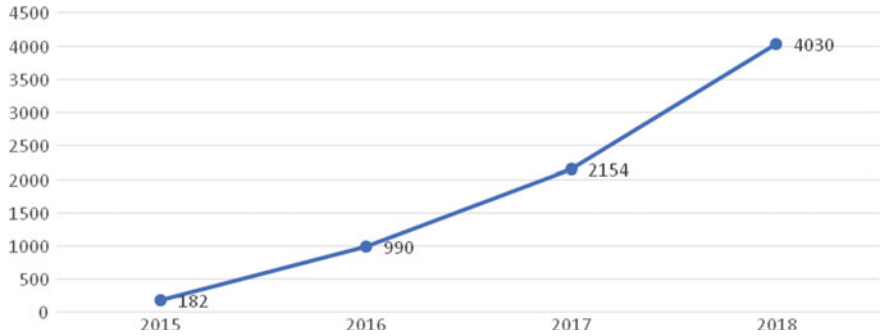

Fig. 3 Dynamics in the number of MOOC, pcs

Among foreign online training platforms that implement MOOC, one may mention edX, Coursera, Udacity, etc.

Among online education platforms that implement MOOC in Russia, the best known are as follows: educational platform "Open Education" which serves as a basis for MOOC of leading Russian universities; Universarium, which by 2019 presented 175 courses in 19 subject areas; Stepik's website, which hosts more than 400 courses [17].

In general, the assessment of preparedness of the educational environment of higher education institutions to the introduction of digital technologies and products shows that only several higher education institutions have implemented automation and informatization and are prepared for digitization. On the other hand, many higher education institutions are still at the initial informatization stage, which includes the formation of IT infrastructure of a university and automation of the educational process. The current level of development of IT infrastructure is indicative of the inadequate digitization of the educational environment of higher education institutions [8].

3.2 Analysis of Preparedness of University Professors for Using Digital Technologies and Products

In order to analyze preparedness of professors of Russian higher education institutions for using digital technologies and products, the findings of NAFI research were used; the level of their digital literacy and ICT competency was assessed in this research [3].

Within the scope of research conducted by NAFI, 634 professors of Russian higher education institutions of various federal districts of Russia were interviewed online.

(1) The assessment of the digital literacy has demonstrated a fairly high score—the digital literacy index for university professors is 88% (Fig. 4).

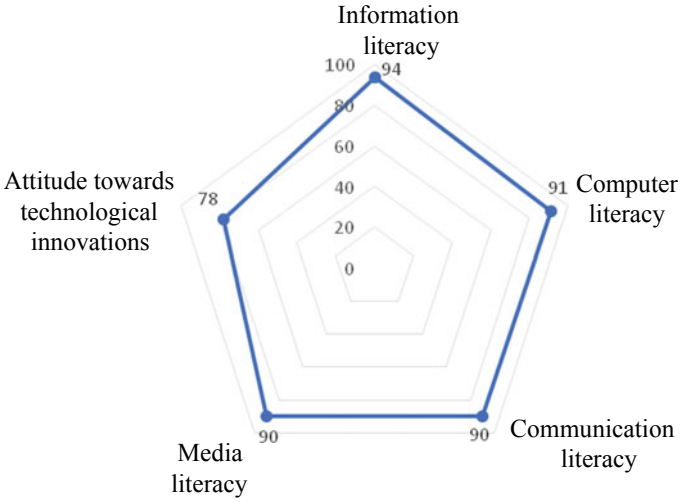

Fig. 4 Digital literacy index for university professors, %

To assess each of the 5 components of the digital literacy index, knowledge, skills and attitudes of university professors in a given field of work with digital technologies and information (Table 1) were identified.

As can be seen from Table 1, the highest percentage is "Information literacy"—94%, and the lowest percentage is "Attitude towards technological innovations"—78%.

(2) The ICT competencies of university professors were assessed using the European Digital Competence Framework 2.0 for teachers (DigCompEdu) [10, 17], which distinguished 22 competencies of teachers, grouped into six blocks:

1. Professional duties
2. Digital resources
3. Teaching and training
4. Assessment of students' performance
5. Expanding the rights, opportunities and independence of students in teaching and learning activities

Table 1 Assessing the digital literacy index by components

Components of the digital literacy	Knowledge	Skills	Attitudes	Indices
Information literacy	97	98	76	94
Computer literacy	83	99	100	92
Communication literacy	87	89	94	90
Media literacy	86	95	91	90
Attitude towards technological innovations	72	84	78	78

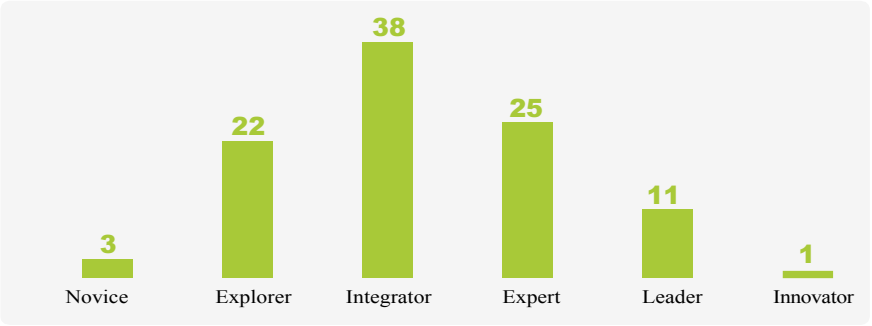

Fig. 5 Distribution of university professors by level of experience in using digital technologies in the educational process, in % of respondents

6. Developing the digital competency of students.

Depending on the level of developed ICT competencies, university professors are classified according to one of 6 experience levels: Novice, Explorer, Integrator, Expert, Leader, and Innovator. The categorization is performed according to the number of points scored in the questionnaire (the maximum total points for all questions in the questionnaire—88).

The identified mean level of ICT competencies of university professors is 45 points.

The distribution of university professors by level of experience in using digital technologies in the educational process is shown in Fig. 5.

As can be seen from Fig. 5, most university professors (75%) have fairly high level of ICT competencies.

The results of assessment of ICT competencies by blocks are as follows.

Maximum score for block 1: Professional duties account for 32% of the teachers surveyed, including in terms of particular competencies:

- Communication with colleagues and students—27%
- Professional cooperation—30%
- Reflexive practices (self-analysis)—31%
- Continuous professional improvement through the use of digital technologies—41%.

Maximum score for block 2: Digital resources account for 36% of the teachers surveyed, including in terms of particular competencies:

- Selection of digital resources—44%
- Creation and modification (adaptation) of digital resources—42%
- Management of digital resources, their protection and exchange—23%.

Maximum score for block 3: Teaching and training account for 30% of the teachers surveyed, including in terms of particular competencies:

- Teaching—31%
- Management of teaching and learning activities—23%
- Collaborative (cooperative) learning—33%
- Self-regulated learning—32%.

Maximum score for block 4: Assessment of students' performance accounts for 37% of the teachers surveyed, including in terms of particular competencies:

- Estimation strategy—32%
- Document analysis—30%
- Feedback and planning—48%.

Maximum score for block 5: Expanding the rights, opportunities and independence of students in teaching and learning activities accounts for 38% of the teachers surveyed, including in terms of particular competencies:

- Providing all students with access to digital devices (PCs, tablets, etc.)—37%
- Differentiation and personalization—35%
- Involvement of students in vigorous activity—43%.

Maximum score for block 6: Developing the digital literacy of students accounts for 41% of the teachers surveyed, including in terms of particular competencies:

- Information literacy—39%
- Communication and collaborative work in a digital environment—54%
- Creation of digital content—51%
- Responsible use of digital technologies—27%
- Solving problems through the use of digital technologies—35%.

Hence, research results suggest the low level of ICT competencies of university professors in all of its components, and, consequently, insufficient level of preparedness for the introduction and active use of digital technologies and products in the educational process [11].

4 Conclusion and Recommendations

The completed research into preparedness of Russian higher education institutions for the introduction of digital education technologies and products allowed making the following conclusions:

- Modern educational environment of Russian higher education institutions and university professors from the perspective of digital literacy and competency are poorly prepared for the active introduction of digital technologies and products [12, 13].

- Today, there are no necessary methodological tools that would enable a comprehensive "inside-out" assessment of preparedness of every Russian higher education institution for the introduction of digital technologies and products, which necessitates development of a comprehensive assessment technique.

Taking into account the above circumstances, research authors suggest assessing preparedness of higher education institutions for the digitization of the educational process on the basis of the analysis of factors that directly influence the digitization of the educational process, in particular: digital transformation of the educational environment of a higher education institution and preparedness of university professors for working in a digital environment.

Teaching IT Specialists with the Help of Online Learning

Irina V. Batunova, Ekaterina I. Lobyneva, Albina Yu. Nikolaeva, and Natalya V. Baturina

Abstract *Purpose*: The purpose of the chapter is to analyze mobile learning for improving students' English proficiency using personal electronic devices and to assess English language teaching and learning supported by electronic media and tools. *Design/methodology/approach*: The authors determine the definition of mobile learning, the classification of devices, the advantages and disadvantages of mobile learning. They consider mobile learning to be an advanced educational technology both in a classroom and for extracurricular lessons for Higher School students of technical specialties. The educational standards of Higher School require solving the problem of future specialists' professional communicative skills development and the authors analyze the ability of mobile learning to meet this task because digital electronic revolution keeps us connected with almost everyone around the world and makes necessary information available anywhere, at any time. Mobile learning can be applied inside and outside the classroom using personal mobile devices. Mobile education extends the boundaries of the traditional pedagogical methods with the effective integration of technology creating a favorable learning environment. *Findings*: It deserves attention that the paper is written completely on the results obtained by the authors during their practical work. They created and tested the exercises with mobile learning applying on the base of "Moodle mobile" which helps teachers to meet the requirements of the constantly changing modern society demands for the professional education development. The exercises selection and systematization gives teachers an opportunity to apply them in their everyday work. They analyzed mobile teaching methods as an advanced educational technology, gave

a scientific review of the mobile education benefits and its drawbacks and suggested the recommendations on the new online practice which is used in the educational environment of technical Higher Schools. The authors underlined the disadvantage that there are some teachers who have not got enough skills to work with personal electronic devices. As for students, they feel free to use them for mobile learning because it enables them to improve their English proficiency. *Originality/value*: Using the tasks and exercises on the base of "Moodle mobile" during the lessons, the authors really confirmed the original concept of the new mobile learning teaching methods applying in the educational activity of technical Higher Schools' students. The authors assessed the authenticity of the practically obtained results, offered practical recommendations for the mobile learning teaching methods, and proved the necessity to integrate the mobile devices into Higher Schools' educational programs for educational technologies modernization with the purpose to improve the English language fluency level of the future specialists.

JEL Classification I21 · I23 · O34

1 Introduction

For several years mobile learning has played an important role in the educational technology. As information and communication technology is changing and developing now, the higher education should respond to the modern trends. According to this tendency, the educational methods and techniques have been used special tools teach a foreign language. Nowadays mobile and online learning is becoming more popular due to the available access to different personal electronic devices that everyone uses in his/her everyday life. A mobile phone is considered to be the most widespread device, so by its using, it is possible and important for any student to improve his/her self-educational foreign-language activity in a technical higher school.

What does mobile learning mean? According to Helen Crompton mobile learning is learning across social and content interaction using personal electronic devices. So devices that are referred to the mobile learning are classified by:

- Different personal devices like iPads, smart phones, laptops, MP3 players;
- Software packages (an operating system, applications, a server software);
- Other facilities that transmit data.

It is important to determine a benefit of mobile learning. There is a need in such methods which improves students' English proficiency inside or outside the classroom. This defines the aim of the article: to identify the possibilities and the

advantages as well as drawbacks of mobile learning and its integration in teaching curriculum improving students' self-learning activity in the English classroom.

2 Materials and Method

When studying a historical overview of mobile learning introduction to the field of the educational technology, a necessity of mobile learning, i.e. its positive and negative influence on students' English independent learning, was analyzed. The analysis of the historical overview found out several researchers, such as Attewell [1], Geddes [7], Cochrane [3, 4], Sharples [15, 16], Reeves [13], Ogata [11, 12], Herrington [10, 9], et al., who are engaged in mobile learning. On the one hand, mobile learning in Russia is not a new educational technology in teaching English in higher schools, but it is used with care and is not paid proper attention to; on the other hand, in some European countries and in the USA this problem has been developed for years and mobile learning has been introduced actively to the teaching curriculum.

Having analyzed researches the aforementioned scientists' researches we underline the following advantages of mobile learning:

- free access to teaching materials both obligatory (within obligatory teaching minimum) and optional ones, e.g. audio and video, moreover, all teaching materials are available anywhere, at any time;
- a possibility of the constant interaction and experience exchange with other students and a full time classroom teacher;
- portability, it being the principal advantage, because almost all personal electronic devices are compact, light and available, they enable students to make notes and enter any data in a device directly;
- a personal device increases students' incentive because they are keen on different gadgets and use them constantly;
- students can approach their teacher outside the classroom;
- students can work at their own pace ([17]: 430).

Having mentioned the advantages of mobile learning we cannot help but noticing some drawbacks, mainly concerning its maintenance:

- the resolution of a personal device screen (it can be low);
- the impossibility of continuous work due to rapid discharging of a device;
- some software not powerful enough to enclose some teaching materials;
- the internet absence or access limitation, including restrictions which a provider gives for the mobile communication.

There is another drawback too: some teachers have disinclination to introducing mobile learning due to their improper skills of working with educational facilities. According to such teachers, students excel them in technical skills and that makes teachers feel nervous [10]. The study showed that even those teachers who have good

skills at working with desktops or laptops can feel nervous using a smart phone ([14]: 65).

Also, some researchers suggest that technology avoiding may become risky for university teachers as they "may become increasingly alienated from many of the students they teach" ([9]: 230). Studying technology is a crucial point for a teacher in order to understand how their students are able to communicate and, on the whole, how fast communication and interaction systems are developing and improving.

One of the simplest ways of tackling the problem of educator's "fear of technology" is to improve teachers' technical skills by constant practice and training and to delegate some technical issues to those students participating in mobile learning who are able to do it. These are technical problems which will be solved because information technology is developing rapidly now ([2]: 12).

3 Results

First, to start the work by means of mobile learning it is necessary to arrange the desktop of the device in order to click on the application which is often used. The icons can be packed in folders or additional desktops can be created for solving different tasks.

The amount of applications which can help to organize e-learning can be downloaded on the device, but this quantity will depend on the internal and external storage of a device. A lot of distant learning systems (course management systems) provide special applications for the comfortable using on the devices. To examine the impact of mobile learning we tested Moodle Application in Siberian Federal University.

Moodle is a course managing system or a learning system, it is considered to be free open source platform which makes its introducing easier. Thanks to this application a teacher can place interactive teaching materials including individual files, lectures, audio and video materials, a book (a source with many pages divided into chapters), a glossary, assignments, databases, etc. ([6]: 50), [5]. Moreover, Moodle enables a teacher to watch over students' course completing by using such settings as "Assessment" and "User's report". To assess students' progress, their strengths and weaknesses, a course element "Test" is applied for placing any possible tests: unit, achievement, mid-course and end of course. "Test" can be set in the definite way having specified a number of attempts and time limit for its fulfillment. The types of test tasks vary from "true/false" to multiple choice questions and an essay. Test marking is done automatically by means of teacher's settings. There is an official mobile application "Moodle mobile" for smart phones and iPads, it can be downloaded from any application market place—AppStore, Googleplay and WindowsStore. Using "Moodle mobile", a student can look through all teaching courses he or she has enrolled for and does tasks offline. A "Feedback" element gives a teacher an opportunity to question students about their course fulfillment and make improvements ([8]: 9).

Let us consider a case study of the "Moodle mobile" application for master students whose major is 040401.08 "Petroleum Chemistry and Refining" (Department "Chemistry and Technology of Natural Energy Carriers and Carbon Materials", School of Petroleum and Natural Gas Engineering, Siberian Federal University). The name of their English course is "Linguistic training" program, full-time course study. The program consists of 3 terms and includes 9 credits, i.e. 324 h. 100% of master students who study this program combine work (mainly shift arrangement) with their studying that is why mobile learning is a benefit here: if a master student cannot attend a class, he or she is able to contact with a teacher via a "Forum" element and with personal course messages. Also, using the syllabus attached within the course a master student can do classroom tasks individually.

Each of the course modules of "Linguistic training" mobile learning lasts for a term. The spring term of 2018–2019 is defined as Module 2 and includes 15 units according to "Career Paths: Petroleum" coursebook, such as "Oil sands", "Oil shale", "Petroleum reserves", "Treating petroleum in the field", "Picking up oil from storage tank", etc. Moreover, the mobile learning course does not replace face-to-face studying in the classroom but supplements it with the assignments which help students to master the course objectives successfully and develop students' competencies.

With this aim in mind we present a sample of the class assignments for a four-hour class period in Table 1 which employs both the coursebook using and "Moodle mobile".

The plan mentioned above is approximate, however, every week some attention has been paid to the "Moodle mobile" application (item 6 in Table 1). Students do the "Lesson" activity, which presents not only content learnt face-to-face succinctly but provides some additional material with diagrams, graphs, etc. omitted in the coursebook and which is important for detailed understanding. Having read the information given, a student does one or more "Glossary" or "Assignment" tasks sending them in the form of the attached files to the teacher. Checking up, marking and grading can be made automatically by means of response patterns entered by the teacher in advance. Moreover, master students can do "Quiz" activity examining their knowledge and skills in units.

When designing and using the "Linguistic training" course in "Moodle mobile", we have come to some points which are crucial for the successful application using. First, the course aims should be clearly explained to the participants and all mobile course tasks have to support those aims. Second, brief and easy-to-read course annotation and user instruction must be developed as an effective means for master students to understand the main aims and each unit objectives and be aware of how to work in the course. Finally, the course syllabus should also be available for the learners—they have to realize what part of the course they are in at the moment and choose their own pace of studying which helps them meet a deadline set for some tasks. Moreover, it is wise for the students to download the mentioned papers in order to have them offline if there are any problems with the internet connection.

We would also like to mention several technical recommendations considering the "Moodle mobile" application. Because of the possible internet speed problems

Table 1 Approximate class assignments with mobile learning on the basis of "Moodle mobile"

Timing	Steps of the lesson	What students do	Patterns of interaction
Up to 10 min	1. Warm-up Vocabulary/grammar revision	One or two revision exercises	Teacher–class, pair work
Up to 25 min	2. Reading, vocabulary presentation	Students discuss the topic Students complete the reading and vocabulary exercises	Pair work Individually teacher–student
Up to 15 min	3. Listening, vocabulary practice, speaking	Students do the listening tasks and discuss the question set in the task	Individually, pair work, teacher–pair
Up to 20 min	4. Listening	Students listen to the conversation; tick the details they hear, choose the correct answer, fill in the gaps, etc.	Individually, pair work, teacher–student
Up to 20 min + 15 min for the presentation	5. Speaking	Using the given conversation models, phrases, vocabulary students make up their own conversation and present it	Pair work Pair–class
Up to 30 min	6. "Moodle mobile" application: practice of the vocabulary and skills	Students complete the «Lesson» and «Glossary»/«Assignment»/«Quiz» activity. Students send their tasks to the teacher. Teacher looks them through and gives feedback	Individually
Up to 40 min	7. Scientific work	Students read the articles which deal with the topic of their dissertation, complete the glossary, do the translation	Individually, teacher–student

the course content should not contain large files, images or other media. Videos must be short and stored in a course in separate folders as some students may download them and watch offline. It is better not to produce a massive amount of downloadable documents as the course browsing in the mobile application will surely be difficult for the students. Instead, the course elements "Book" or "Lecture" could be employed. We also believe that timing and setting deadlines should be paid special attention to because of the disadvantages of mobile learning mentioned in part 2 Materials and method. If we speak about assessing of the students performance by means of the "Test" element, then it would be better to let students have two attempts to complete the test.

4 Conclusion

Thus, mobile learning implemented on the base of "Moodle mobile" system meets two main criteria: first, it helps to improve students' English proficiency, use vocabulary which a master student need in his/her classroom and scientific research; secondly, it provides scaffolding for the master students who have missed classes.

To sum up, the benefit of using mobile devices in the field of educational technology is expected to be obvious. Using mobile learning properly and systematically in the teaching industry is able to upgrade educational technology and increase students' motivation in a foreign language learning and the educational level of the population due to teaching and learning supported by electronic media and tools throughout the world.

Productive Assessment Used as Important Means of Technogenic Society Development

Vita V. Vonog, Irina V. Batunova, Natalya V. Baturina, and Anna A. Struzik

Abstract *Purpose/value*: The article is devoted to productive forms of assessment in teaching English for specific purposes to students within technogenic environment. The authors investigate the assessment tools by means of technology enhanced methods as well as traditional ones that contribute to cross-cultural professional communicative competence reflected in the goal of foreign language teaching at non-linguistics universities. The main features of productive assessment are described in terms of approbation of e-courses, key characteristics of the system are given, the main conditions of the organization of educational process are revealed. *Methodology*: The authors describe a methodological basis for designing a productive assessment system corresponding to the specific character of technogenic society education, specifies the main functions of new tools of assessment and defines the peculiarities of that activity. The article deals with explaining the use of traditional and innovative approaches with emphasis on a learning individual's educational content and personal softskills development. *Findings*: According to authors' point of view, the use of information technologies tools as well as technology enhanced assessment are based on principles which tend to challenge traditional learning and teaching practices and thus impact on technogenic society development. On the other hand, piloting theses technologies outlined a perspective range of problems to be addressed in further research concerning Higher education.

1 Introduction

Nowadays one of the most topical issues seems to be the process of changing human life due to integration and the active technology use. These conditions allow to consider modern society as a technological one which includes blending technological and scientific approaches as the technosphere basis while considering social structure in general terms. Polyparadigm of the given aspects generates demand in the modern society and highlights its key-features. The main factor is the increasing importance of technology, which is observed in all spheres of human life.

Taking into account that education today is one of the basic aspects in human life, there are disciplines focused on the study of the learning process and its impact, its transformation in the technogenic environment (Science, Technology and Society (STS), Learning Studies). Because of this, the technologies are considered not only as equipment and tools, but also as a means to achieve the greatest efficiency by means of implementing different economic theories into practice [17].

According to Bonk and Graham [1], students, in their turn, need to formulate terminal learning objective, to define and develop their own style of teaching and work out the individual plan of work. Moreover, Watson J. states that a teacher and students work together, thereby providing the quality of teaching and accompanying the educational process an independent, useful, effective and motivating to the development approach [28]. The study of the society becomes relevant not only due to the high demand and society's focus on cybernetic factors, but also on such a factor as the highest level of efficiency.

However, along with changes in the process of education in a technogenic society transformed by new technical means, the prototype of the modern student is changing. The development of the Internet technologies and the inclusion of social networks, electronic portfolio, mass online courses, interactive tasks, e-storage and implementation of the material, etc. are due to new features in the student's learning.

In connection with this, the modern Higher school faces a difficult task: to create conditions for the future specialist of a non-language profile for successful educational and professional activities. The analysis of scientific data provides arguments in favor of transforming the present-day teaching methods in compliance with the current methodology and the social demand which is reflected in the goal of a foreign language teaching at non-linguistics universities [25].

There are many technologies that are actively introduced by higher school teachers in the educational process: the technology of distance learning using blended learning [6, 16, 23, 24, 27, 33,], e-portfolio technology [9, 10, 21, 22], the foreign language profile of profession [25, 32], modular training [4], case-study. Among advantages the

authors define the taxonomy of students achievements obtained in the educational activity which allows to track the process of learning outcomes; a possibility of individual approach used in a group training. It doesn't take a lot of time to define the level of proficiency in a foreign language, to monitor dynamics of factors by means of analyzing the achievements and gaps bridging compensation.

In our paper we focus our attention on assessment tools used in teaching a foreign language to students of engineering profile to reach the goal of the study, i.e. passing the examination on the discipline «Foreign Language». According to analyzed test results of some higher school students we made preliminary conclusions concerning the efficiency of the methods and assessment tools applied by the English teachers of Siberian Federal University (SibFU). Among conclusions particularly relevant to our research are those concerning the use of profession-oriented situations and students' creative work [22, 31, 33] as instruments of assessing professional development. Promising results were obtained in connection with alternative methods of evaluation in teaching foreign languages to students of engineering majors [13, 26], flexible evaluation criteria of the European Language Portfolio [30], as well as digital tools of assessment [3, 15, 20, 29], etc).

2 Methodology

In terms of assessing students progress teachers use creative forms of their feedback connected with professional sphere of the student where each participant becomes an integral part of educational environment. This kind of assessment is often called productive assessment as it is aimed at developing students autonomy and individual track of the progress. By means of productive assessment students obtain communicative competence, the availability of organizational skills, the ability to work in a team. "The value-semantic attitude to professional activity is formed under the influence of the global context of the development of the profession, taking into account world trends, the experience of others countries and peoples in the studied subject area" [32].

There are a great deal of studies concerning different methods and approaches in teaching a foreign language accompanied by various means of assessment. To carry out our research, twenty-nine teachers of the Department of Foreign Language for Engineering SFU were interviewed. According to the survey aimed at choosing the most common methods, we obtained data presented in Fig. 1.

Grammar translation method is a widely used one applied by the Soviet teachers. The aim of this method is to teach written translation to students first of all. According to this method teachers have to make up texts to introduce certain grammar structures and rules, thematic vocabulary, spelling. Then, grammar texts are used for further language practice. Obviously, nowadays the method is not widely used in modern teaching but can be applied studying dead languages, i.e. Latin.

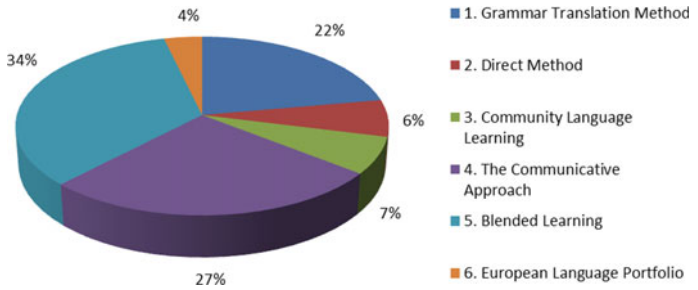

Fig. 1 Methods and techniques commonly applied by teachers

Direct Method (or natural Approach) is used for mastering a language from the beginning. Students' mother tongue is prohibited during the lessons. The idea of this method is to create a "complete language surrounding" for students.

Community Language Learning includes a lot of interactive exercises such as group and pair work, role playing, surveys, etc. This method is used on every stage of the modern education because it lets control and use students' knowledge and skills both in tasks and communication with a teacher during the lesson and inside the group.

The Communicative Approach is one of the most widely used and preferred modern teaching method. It appeared in Great Britain when a new educational aim was formed in its teaching system. Its aim suggests mastering a foreign language as a means of communication, providing information exchange during the communication process.

Blended learning means creating a virtual environment for virtual e-learning, which includes tools for preparing and delivering educational content, as well as educational management tools process. A number of developments in learning sciences have contributed to a deeper understanding of the relationship between feedback processes and effective learning [29]. Such developments have particularly acknowledged the importance of learner self-regulation and peer-assessment in deeper engagement and effective learning [14, 20]. Another emphasis on developing and assessing characteristics and dispositions of learners that augment more traditional areas of the curriculum—often classed as 'twenty-first century skills'—has also become a familiar mantra within the field. This focus acknowledges the digital and participatory worlds that children and young people increasingly need to negotiate [7].

European Language Portfolio that can be defined as "… a flexible educational tool that can be adapted to almost any learning situation, depending on the purpose of instruction, the age of the trainees, the stage of language proficiency, the learning conditions, the individual style of the learning activity, and the methods and means of instruction" [4].

Professional growth and obtaining metadiscipline competences are typically measured by means of the following assessment tools, presented in Table 1. Besides the table demonstrates its assessment strengths and weaknesses (Table 1).

According to the survey we came to conclusion that innovative approaches as well as assessment tools motivate students for taking on new participatory and collaborative roles in learning online and outside the classroom, and there is a growing interest in incorporating these roles and practices inside education. To define students progress, the authors carried out a placement test among 97 second-year engineering

Table 1 Assessment tools used in different methods

Method	Objectives and teaching principle	Strengths	Weaknesses	Assessment tools
Grammar Translation Method	Translation, understanding the content, ability to render in the Russian language	Students understand original texts, study grammar in the context, the Russian language serves as a means of semantics	Language teaching leads to learning grammar; inactive work is used; great attention is paid to translation while speaking skills are ignored	Grammar exercises, tests, text translation
Direct Method	Communication, attempt to strike a balance between the Russian and the foreign languages	Great attention is paid to phonetics, grammar accuracy. The learning consists of programs where the language material is provided sequentially, teaching is done by native speakers	Mother tongue is not used at all, students are required more hours for studying, teaching is done by native speakers	Grammar tasks based on the comparison of the two languages, translation, back-translation, retelling of the texts
The Communicative Approach	Everyday communication, solving sociable problems	Students use some communicative drills for social interaction	It is difficult to teach and consolidate grammar structures, ambiguity in assessing written/oral skills, availability of pseudo-communicative activities, the main focus is routine communication	Monologues speculation, dialogues, case-solving tasks

(continued)

Table 1 (continued)

Method	Objectives and teaching principle	Strengths	Weaknesses	Assessment tools
Community Language Learning	Interaction, teaching for collaboration, solving problems together, practice orientation	Great attention is paid to learning oral speech, a lot of group work, ability for a student to choose speech patterns for learning.	Restriction in using the method for ESP (English for Specific Purposes) teaching, a teacher has to have some pedagogical experience as well as psychological one for lessons conducting, decline of productive	Dialogues, presentation, case-solving tasks, question-answer form of work
Blended learning	Combination of traditional approaches with including online interaction	Immediate feedback of the teacher and group mates, time-flexibility and convenience	Internet access, direct contact	Chat, forum, blog, Wiki, peer-view, on-line tests, pools, interactive online games, online platforms
European Language Portfolio	Collecting records of different task assessment to reflect learner's skill-development	Making individual progress track, structured form	Low motivation, difficulties with organization	Self-assessment checklists, creating professional glossary, tests, essays, projects

students in Siberian Federal University (the speciality of 08.03.01.01 Civil Engineering). Figure 2 shows that the main level of proficiency is Basic User; some students have self-sufficient level of English (Independent User).

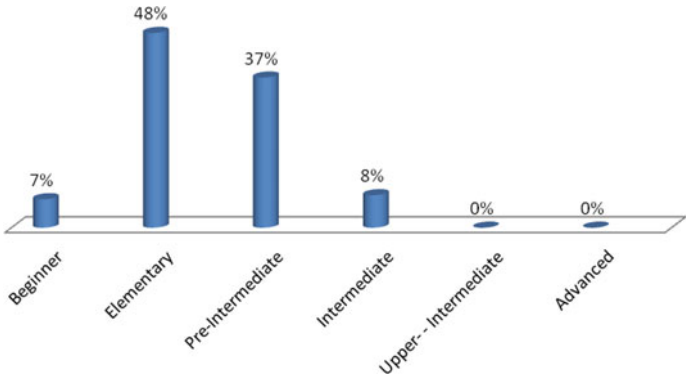

Fig. 2 Test results of second-year students

Thus, to organize learning process the authors relied on two levels of English: Elementary and Pre-Intermediate. Furthermore, in order to form a group of students it is reasonable to unite students with Beginner and Elementary levels in one group and the learners with Pre-Intermediate and Intermediate ones in the other.

When analyzing scientific data a problem of discrepancy between the applied methods and the aims during the English teaching was found. The study conducted during the lesson attendance and peer-observation showed that the results of the English teachers' activities and assessment tools were not always productive. The authors believe that is due to the fact that of the students' different English level as well as the various teaching methods and assessment tools applied by the teachers who mainly use one of the methods (e.g. grammar translation method or direct method, etc.). Thus, the methods proved to be perceived by the students, each forming a definite language skill. The problem is that students are not able to solve situations within the competence approach according to Federal Education Standard in Higher Schools 3+ realized in Siberian Federal University.

Having analyzed teachers' activities and assessment tools at the English lessons we can conclude that a practical lesson should include a set of criteria for the lesson efficiency covering all the curriculum components mentioned by the authors and paying attention to teachers-practitioners' opinions should also be employed.

Relying on the data study the authors define the main aim of the research as to increase the efficiency of the teaching process at the expense of combining various teaching methods and assessment tools. Within the competence approach according to Federal Education Standard in Higher Schools 3+ realized in Siberian Federal University, for the final examination the students must (1) be able to translate a special text in the written form by means of a dictionary for a limited period of time; (2) talk to the teacher about the text read without a dictionary, answer the questions about its content, express their opinion about the text (i.e. discussion); (3) present their project in English (a layout or a drawing of a residential house, a bridge, a highway or a building structure) and answer the listeners' questions.

For the successful curriculum realization and achievement of the aim assigned the authors tried to organize the experimental group study to connect the teaching method with the final test. The students were divided into 2 groups. The first group included 48 students with Elementary and Pre-Intermediate levels. They are taught by a teacher using just one of the methods. The second group included 49 students also with Elementary and Pre-Intermediate levels, however, the teaching process was arranged differently. Blended Learning and Grammar Translation Methods were used to develop translation skills; the combination of Grammar Translation Method and the Communicative Approach was applied for text reading and understanding, as well as discussing it; to make presentations the teachers used European Language Portfolio, Direct Method, the Communicative Approach and Community Language Learning. The experiment lasted for a term (four months). Due to blended learning the efficiency of the study process inclined. Having included online means, it became possible for the students to drill the given material outside the class and to receive feedback from the teacher or groupmates instantly without feeling hesitated or destructed (using chats, peer-viewing, on-line tests, forum etc.). In this case, online means make the

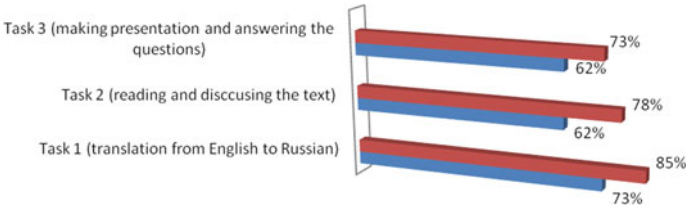

Fig. 3 The experiment results

process more convenient and keep the student more motivated and interested in the process because of the new interactive format.

3 Results

The results of the experiment are shown in Fig. 3, where the first group (48 students) is noted with blue, while the second one (49 students)—with red, also the proportion of the students who have coped with the tasks successfully within the certain period of time could also be seen.

Obviously, the results in the second group are higher than in the first one. The authors believe better results are caused by applying such teaching methods and assessment tools which are connected with the achievement of the final examination aim. The proficiency level of the methods used is defined by testing the students.

4 Conclusions

Our study is to search the productive assessment tools as well as teaching methods in technical schools for fulfilling the aim assigned, which is to pass a final examination on the subject of a foreign language. The results obtained during the research can be used for the increasing teaching process efficiency in technical schools.

The usage of Grammar Translation Method for teaching English in technical schools is considered in the works of Fry et al. ([5]: 329, 336). They have a positive attitude to its application in addition to the Communicative Approach. Though foreign language teaching is studied by contemporary methodists as an interactive social cultural process dedicated solving communicative objectives ([2]: 12). Furthermore, the researchers believe that using some Grammar Translation Method techniques improves the teaching process efficiency ([8]: 22–28), especially for the students with a low language level as you can see on the examples of Task 1 in Fig. 3. The same can be noticed about Task 2 preparing which is reading and text discussion. The vocabulary chosen for the text about the students' specialty as well as texts written specially for teaching purposes can be used for teaching in technical

schools ([18]: 4) together with the Communicative Approach, which allows to both check task fulfillment, accuracy and involve students into expressing their own attitude about the text being read, sharing information by means of some techniques ([12]: 113–115).

The combination of Direct Method, the Communicative Approach, Blended learning and Community Language Learning enables to overcome a language barrier because students are often afraid of making mistakes during the lessons and while communicating with foreigners [19]. Subsequently, instead of searching one eclectic teaching method a teacher can use the combination of some methods or postmethod [11]: 161–184).

Despite the results obtained, the theoretic basis of our article is corroborated, experimental data are not finally confirmed. The assessment of the applied method efficiency will be possible after a further study, but it goes beyond the bounds of our research. That is novelty of our work; our experiment and theoretic basis can define the applied method efficiency in the curriculum. As far as the aim of the foreign language teaching in technical schools can be changed, it is necessary to study the teaching process. Because of the teaching aims being changed and limited hours for teaching a foreign language, special topicality within vocational education is to search an opportunity for the increasing teaching efficiency on the base of defining the applied methods efficiency in practice.

To achieve teaching objectives effectively, it is necessary to define appropriate assessment tools suitable for taking final examination. Due to the teaching aim a teacher should choose productive assessment tools which reach the goal. Peer review is suitable for translating authentic professional texts; online tests, chats, Wiki are the most appropriate for teaching reading and text discussion; Pier review, blogs, chats help to present students' projects. All of these means contribute to student's autonomy. That gives an answer on the question why so many educational institutions address to social networks and chats usage (for example, integrating them into the learning process) as part of the interactive aspect between students and/or the teacher. In particular, creativity and desire for leadership are developing, which is increasingly taken into account in the assessment reporting forms for the student.

The use of e-courses, electronic journals and interactive online tasks make the learning process more accessible, since the simplification due to technical means is taken into account as well as psychological characteristics of the student. This allows to create the necessary and comfortable conditions for professional development.

Implementing virtual environment in teaching a foreign language helps to form the ability of students to plan and organize, evaluate and adjust their learning activities, focusing on the final result. This form of work allows the learner's autonomy, which makes it more effective in a competitive educational environment. Due to productive assessment students learn to make decisions, make choice and take responsibility, develop skills to work in the information environment, search for data, select and analyze information independently, present results by means of various modern technologies. Moreover, due to the development of autonomy of students in the process of training, the scientist will be able to take responsibility for making decisions in

professional activities, transfer knowledge and experience to new professional situations, adequately assess their professional capabilities and, if necessary, fill the gaps in knowledge and experience.

Life Attitudes of a Modern Woman Chief

Irina V. Dolgorukova, Tatyana N. Yudina, Tatyana N. Fomicheva, Evgeniya E. Kiseleva, and Evgeniy A. Lidzer

Abstract *Purpose*: The purpose of the paper is to assess the life attitudes of a modern woman chief, which involve work motives and incentives, goals and means, visions of the success and issues of intention to be materialized. *Design/methodology/approach*: The paper offers an analysis of conceptual approaches to the study of women's leadership issues. The background of the paper is also the findings of a sociological survey conducted at the Russian State Social University in 2019. The main research method is a computer-assisted web interviewing of women working in Russian enterprises. Also, 15 in-depth interviews were held with women filling senior positions. *Findings*: In the course of the paper we identified the main components of the personal and business behavior patterns of women chiefs. Finally, we concluded that the majority of women chiefs prone to a forced or mixed type of business activity. The commitment to income growth as the main incentive for climbing the career ladder is explained by the troublesome economic situation, economic crises and downfalls of recent years. A woman needs to financially assist to herself and her family, and this is the first incentive for career growth. *Uniqueness/value*: The theoretical summaries and conclusions presented in the article supplement the current knowledge concerning various social roles and statuses of women, specify the basic concepts of leadership theory. The findings can be useful for business chiefs, entrepreneurs, public characters and a wide range of readers.

1 Introduction

Today, the position of women in the family and society has dramatically changed. In many countries, there is a trend of aggressive self-fulfillment and leadership of women in various areas of society.

In the last 2–3 centuries, women have stood up for their rights. As a result, they have gained equal rights with men in developed countries [1]. That's why in the lives of women arise other roles, in addition to the traditional ones of mother and wife, which are no less important and labor-intensive (employee, colleague, public woman and so on). Over the years the number of women holding senior positions in the developed economy is growing [2]. However, the prejudice about a woman as an employee who cannot and must not perform leadership functions have not yet overcome [3].

The government efforts on improvement of the women position at work, the development of the feminist movement, an ideological campaign aimed at changing the public opinion on women's leadership, the evolvement of small and family businesses as the most important areas of female self-fulfillment have become the main factors that can change the role of women in economic development and society in general [4].

The relevance of assessing the life attitudes of women chiefs is related to simultaneous requirements to women in terms of job and family under a female model of career growth in contrast to the male one. Such a situation puts obstacles to professional development [5]. This in turn often induces the occurrence of role conflict and role overload.

2 Materials and Method

The issues of female leadership are multidisciplinary and associated with research areas as management sociology, personality sociology, psychology, economics, and law [6].

Within the management sociology, special attention is paid to leadership theories (M. Weber, J. Homans, F. Fieldler), as well as leadership styles (G. Andreeva, T. Kono). Economic motivations and types of rationality are thoroughly studied in economic sociology. This topic is addressed in the works by G. Simon, A. Maslow, J. March, F. Hayek. A. G. Kharchev, S. I. Golod, A. I. Antonov, S. E. Baskakova

dealt with the problem of family and motherhood, a combination of the social roles of women as employee and mother.

The issue of a woman's life values is highlighted in the writings by L. L. Osadchaya. The theoretical insights into the definition of life attitudes were considered in the works by L. S. Egorova, O. M. Zdravomyslova. The development of life attitudes was investigated by N. A. Kigai, N. F. Naumova, T. E. Reznik, Yu. M. Reznik, E. A. Smirnova, et al.

The background of the article was made up by the findings of a sociological survey held at the Russian State Social University in 2019. The main research method is a computer-assisted web interviewing of women working in Russian enterprises. Also, 15 in-depth interviews were held with women filling senior positions.

3 Findings

Bearing in mind the diversity of the modern world, it is a common practice to distinguish the types and vectors of life attitudes depending on the importance of one area of life in the general structure of human development [7].

So, for example, V. Yu. Mamaeva distinguishes two types of women's economic behavior strategies. The first is a survival strategy (dependence on the state social support) and the second one is a development strategy (self-reliance in achieving career goals) [8]. At the same time, it is important to separate the areas of a woman's life. From this point of view, we can enumerate two strategies of behavior:

- personal strategy (it's about the ability of a person to satisfy and achieve a specific set of needs and goals chosen in self-cognition and self-fulfillment as priorities);
- business strategy (the ability of a person to fulfill a particular set of career needs and goals).

The extent of unleashing the woman's potential, self-fulfillment, as well as life satisfaction, depends on the performance of life strategies.

According to "Gender Equality poll: The Situation Has Changed For the Better in Russia!", over a third of Russians believe that it has become easier for women to hold a senior position at work (34%) or set up their own business, to unlock the potential in public and political area (40%). However, starting a family, having and raising a baby is getting harder (42% and 50% respectively).[1] The findings indicate the broader opportunities of women in the field of social and productive labor due to some troubles in private life [9].

The author's study revealed that 88% of the polled employees were convinced that a woman should work. Moreover, over half of the respondents (69%) believe that the

[1] Initiative All-Russian poll was conducted by Russian Public Opinion Research Center on February 14–15, 2015. The poll covered 1600 people in 132 settlements located in 46 regions, territories and republics of Russia. Margin of error is not higher 3.5%. [Electronic resource]. URL: http://infographics.wciom.ru/theme-archive/society/religion-lifestyle/gender-problems/article/ravenstvo-polov-v-rossii-stalo-luchshe.html (accessed 18.01.2017).

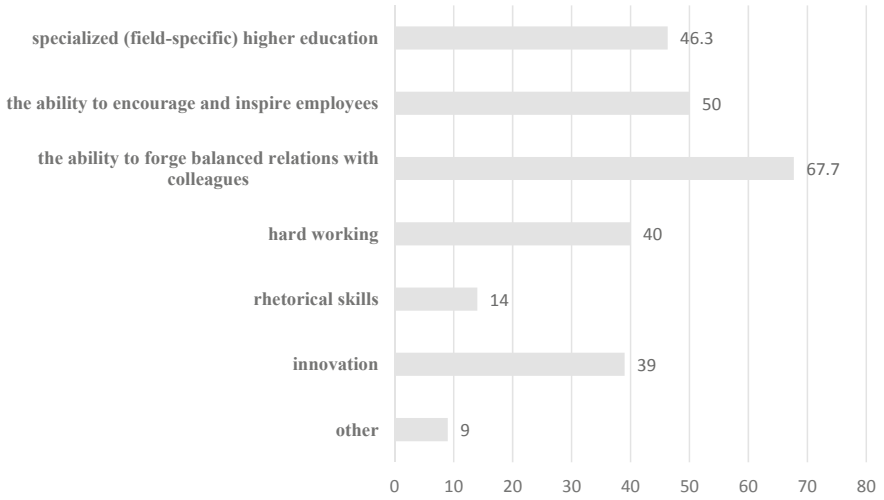

Fig. 1 Competencies essential for a woman chief in the opinion of the company's staff (percent from the number of surveyed, multiple questions)

career promotion opportunities for men and women are equal. However, slightly less than a third of surveyed (29.7%) are sure that men have more career opportunities and 1.3% think otherwise.

In the opinion of the company's staff, the three major competencies of a woman-chief are the ability to forge well-balanced relationships with colleagues (66.7%), the ability to encourage and inspire employees (50%), specialized (field-specific) higher education (46.3%). Then, surveyed selected qualities such as hard-working (40%), innovation (39%), rhetorical skills (14%) and others (9%) (Fig. 1).

The nature of the relationship between the chief and the subordinate shapes a particular climate within the team, as well as help to assess the expertise and goals of the boss (Fig. 2).

The democratic leadership style prevails among women chiefs working in all types of companies. Thus, this style is typical for 43% of healthcare companies, 49% of service companies, 42% of educational institutions, 36% of financial companies, and 50% of marketing and advertising agencies.

The staff of Russian companies most often define their chief as a "mentor" (29%), "partner" (20.6%) and "chief" (15.3%). Just over 10% of surveyed have chosen the answers "superintendent" and "supervisor" (Fig. 3).

Investigating the ideas of woman chiefs about personal and business growth, firstly we tried to know what they mean. Thus, describing a business strategy, all participants of in-depth interviews associated this notion primarily with a career. As for the personal strategy, the interviewed defined it as self-development and self-education in fields out of professional activity.

Taking into consideration the findings of in-depth interviews, we made up a rating of the life values of the woman chief. At the top of the rating, there were family, public

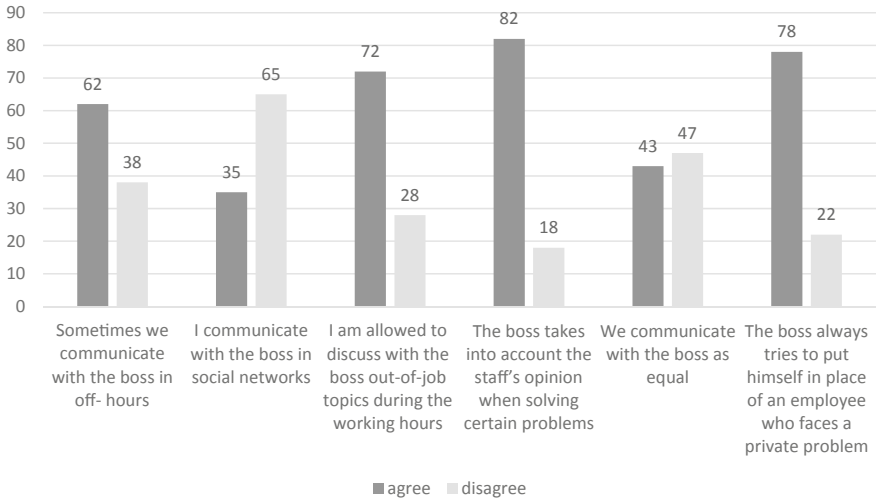

Fig. 2 Judging by the company's staff the statements regarding their relationship with a woman chief (percent from the number of surveyed, multiple questions)

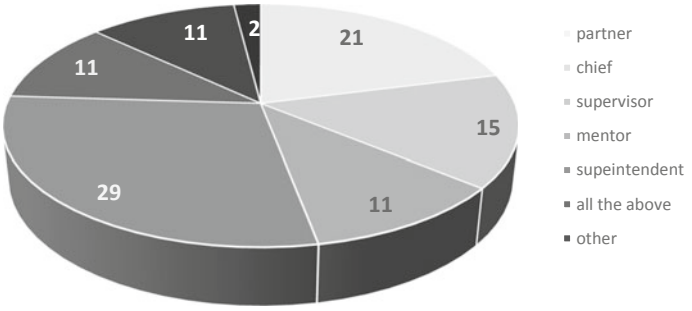

Fig. 3 Strategies of a woman-company chief in the eyes of staff (percent from the number of surveyed, multiple questions)

esteem and popularity, as well as self-fulfillment. In the middle of the rating, there were love and romantic relationships, welfare, health, and friendship. Freedom and independence, creativity and hobbies, as well as a career were evaluated by women as secondary. "A successful woman is a happy woman"—this statement was uttered by the general director of the tailor house-figure skating shop "LEDO". The strategy with the balance between family, private life and career is prevailing. It is the time management skill is one of the major indicators of a woman's success [10–13].

4 Conclusion

The life strategies of the woman chief as an object of sociological research can be studied both from a business and a personal perspective. Along with the notion of "life strategy", "life path", "life vector", "life scenario" and others are in use.

In the course of the analysis of the research findings, we've made a conclusion that a mixed type of business activity (mainly with external motives for climbing the career ladder (forced type) and will of self-fulfillment in the business area) is inherent in a woman chief.

The personal strategy of a woman chief includes, first of all, self-fulfillment, self-cognition and self-development in out-of-career fields, a particular moral and social growth. The financial incentive when a woman wants to improve the financial status of her family is equally important.

A business strategy is foremost associated with the achievement of certain career goals, enhancement of authority among employees, and also promotion of competitiveness. The woman chief recognizes the need to balance personal and business strategies, not to sink in career, make efforts to start and foster your family.

Business growth is understood by a woman chief as continuous climb into the career ladder and appreciation of her merits by colleagues. Personal growth is expressed in self-fulfillment, as a rule, in out-of-career fields, like hobbies or family relationships.

Financially Literate Behavior in the Course of Achieving National Goals and Strategic Objectives of Russia

Oleg V. Kuznetsov, Marina E. Rodionova, Igor S. Shevalkin, and Anatoliy V. Ivanov

Abstract *Purpose*: The relevance of this issue has been raised due to the demand for a forecast of the needs of the financial and economic segment of the market in the content and models of financial literacy in the process of achieving the national goals and strategic objectives of the development of the Russian Federation for the period up to 2024. The chapter presents an analysis of current issues of improving financial literacy, provides a detailed description of the main target groups on the basis of the Strategy for Improving Financial Literacy in the Russian Federation for the period 2017–2023, and presents the results pilot studies of a condition of financial literacy, financial competent behavior of the population and determining from factors on the example of one of the main target groups—school students. *Design/methodology/approach*: The authors have measured the possible financial strategies of a today's schoolchild using a quantitative survey, as well as a semi-gamified approach. The conducted sociological research in the framework of the scientific paper "Institutionalization of financial literacy of the Russian population" is a necessary element in assessing the level of financial literacy of the population of Russia, based on the use of a set of methods to determine the level of financial literacy for developing measures to increase its effectiveness. The authors conducted a mass face-to-face survey with 731 students involved using the survey method. Senior students aged 16–18 years answered our questions. Respondents from 66 regions of the country were interviewed. *Findings*: The young people's self-esteem of their own financial literacy looks quite self-critical. Hence, approximately 2/3 of the respondents surveyed consider themselves more or less financially literate

1 Introduction

The relevance and novelty of the topic assumes importance due to the developing institutional basis of the population financial literacy improvement and support system in the Russian Federation against a backdrop of expanding the range of financial services that require new competencies from consumers. Against this background, it is essential to prioritize the questions of linking the level of financial literacy with the financial literate behavior of target groups of the population, the active use of a dynamically expanding list of financial instruments with regard to lifestyle features, available financial resources, and the goals of individual entrepreneurs, small and medium-sized businesses, as one of the key projects of the Financial University [1, 2].

It is also relevant to use financial literacy programs to prevent financial fraud, build confidence in financial institutions and develop personal positive financial strategies for higher household prosperity, as well as for government monitoring.

In the Russian Federation, financial literacy is considered as the result of the process of financial education, which is defined as a combination of awareness, knowledge, skills and behavioral models required for making successful financial decisions and eventually for achieving financial health. This understanding of financial literacy is used when drawing up strategic planning documents and in law enforcement practice.

A country population appears to be the main consumer of financial services as well as the target audience of financial literacy improvement strategies aimed at covering various strata of society. It appears to be important to obtain reliable and solid information about financial services and products for both the population as a whole and its individual groups due to a number of reasons, such as a dynamically

changing financial market, conditions of financial and economic crises, the constant complication of financial services and products offered on the market, various kinds of tools.

According to the financial literacy improvement strategy in the Russian Federation for 2017–2023, as well as the conceptual population financial literacy institutionalization model of the Russian Federation that we developed during the study, we identified priority target groups of the population, which include: (1) students of general educational institutions (schoolchildren), (2) students of vocational schools and higher education institutions (students), (3) the adult population, divided into two groups: low- and middle-income individuals, high-income individuals, (4) the retired and citizens of pre-retirement age.

Schoolchildren and students represent the future economically active population. Their features, as financial literacy programs participants, "are subjected to the high capability of schoolchildren and students to shape adequate values, develop financial planning skills and well-minded behavior." An analysis of international experience also confirms that this group is deemed promising in most financial literacy development programs. For example, in France, the school curriculum annually focuses extensively on a detailed study of one of the topics of financial literacy.

According to the Financial literacy improvement program in the Russian Federation, private initiatives in improving financial literacy among schoolchildren and students are expected. In some regions of Russia, the school subject "Financial Literacy" has been introduced. In most cases, financial literacy is included in the course of social studies or economics.

It should be noted that according to the "Promoting the level of financial literacy of the population and the development of financial education in the Russian Federation" project, children are considered as a means of influence on their parents. Given the degree of illiteracy of the older generation, schoolchildren will be able to influence their parents, who are not used to planning a family budget due to the "peculiarities of the Russian mentality," and after 10–15 years it will be safe to say that "the population will become more literate".

2 Materials and Methods

We've measured the possible financial strategies of a today's schoolchild using a quantitative survey, as well as a semi-gamified approach, that is, respondents were asked an open question in the manner of Pushkin's fairy tale of a goldfish.

The empirical measurements [3] that we made were based on the main social problem that is the ever-increasing pace and amounts of innovative financial tools introduction on the one hand, and the carefree childhood and youth of the younger generation, which is replacing us, on the other hand. Can we hope that future generations will have decent living standards? Will they be able to adapt in time to the innovative stream rushing towards them, including to financial innovations?

Therefore, the object of our research is Russian schoolchildren. The concentrated expression of the relationship between the social problem and the study object is the subject of our sociological research—the financial literacy of the study object.

To solve this problem, we conducted a mass face-to-face survey with 731 students involved using the survey method. Senior students aged 16–18 years answered our questions. Respondents from 66 regions of the country were interviewed.

The majority of respondents are residents of Moscow (38.8%) and the Moscow Region (20.9%). In the survey, men make up 36.8%, women—63.2%, which is typical for a humanitarian university. As for the size of the locality of the surveyed young people, the entire variety was presented from a rural locality to a metropolis with a population of more than a million people. Moreover, 49.9% of the respondents live in metropolises, while another half 50.1% represent seven other nominations in the Russian Federation's settlements: a large city with a population of 500,000–1 million people; a large city with a population of 250–500 thousand people; a large city with a population of 100–250 thousand people; an average city with a population of 50–100 thousand people; a small town with a population of up to 50 thousand people; urban village; rural settlement.

3 Results

The answers offered by schoolchildren to the semi-closed multiple question "What knowledge and skills make a boy or a girl a financially literate person?" Demonstrated that "the capability to effectively manage personal finances" is the leading answer—this is the choice of 80.6% of respondents. Although this is the expected answer. Other figures turned out to be ultimately more interesting—76.2%—these are people who consider one of the most important features of financial literacy "mastering financial tools to achieve your goals". That is, more than ¾ of today's young people have a mature approach to financial literacy, essentially at the subconscious level. After all, this answer relates to the closed part of this question. Furthermore, we draw attention to the fact that if the goals that schoolchildren strive for (getting a degree, making a family, achieving success in a career or professional growth, starting their own business, etc.) are in demand in modern society, then achieving them using modern innovative financial tools—is an indicator of a fairly high financial and economic maturity of modern Russian society. Besides, almost 2/3 of students emphasis the thesis "the capability to understand the features of various financial products and services" (63.9%).

Answers such as the availability of an electronic wallet (1.2%), or the use of a credit card (3.0%) in terms of significance are within the statistical accuracy of the study, which speaks volumes. First of all, the Russian schoolchildren are aware of the fact that the availability of real financial resources, even on innovative media, is not nearly a sign of a person's financial literacy. Please compare 76.2% (mastering financial tools to achieve your goals) and 1.2% (availability of an electronic wallet). These figures differ 63.5 times!!!

The young people's self-esteem of their own financial literacy looks quite self-critical. Hence, approximately 2/3 of the respondents surveyed consider themselves more or less financially literate (61.3%); approximately one in ten found it difficult to answer, and a little more than a quarter said "rather not" (28.7%).

The possible financial strategies of a today's schoolchild were measured using a semi-gamified approach, that is, respondents were asked an open question in the manner of Pushkin's fairy tale of a goldfish. It sounded like this: "Imagine a situation in which you have your own free financial resources that you do not need to give back, in the amount of 150 thousand rubles. How would you manage, spend, invest, use them in the financial market?". The children were asked to answer in any form. As a rule, respondents expressed several alternatives to their behavior, for example, to deposit part of the money in a bank, spend the other part on high-yield stocks, and spend the rest on traveling. But neither of respondents gave more than three alternatives at the same time. Therefore, we have grouped the answers of schoolchildren into seven possible topics and prepared a categorical variable on a multiple question with three possible answers. We suggest to consider the proposed topics as future financial strategies of respondents: investment in deposits—40.5%; investment in securities (and, as a rule, in stocks)—19.3%; investment in starting their own business—13.4%; spending money on oneself—13.3% (this includes cars, travelling, and expensive devices, etc.); found it difficult to answer—9.7%; various other expenses (parents, charity, housing conditions, etc.)—8.2%; investment in own education, unfortunately, only makes up 7.4%.

Furthermore, when drawing up such a categorical variable we can also consider the empirical dependencies that we identified depending on gender, income, place of residence, etc.

The first one. Young people from low-income families are almost twice as likely to deposit money. They are almost two times more likely to start their own business. They are much more likely than others to invest in securities (25–21–17.8%).

The second one. None (!!!) of the low-income respondents surveyed will spend the easy money on himself. Whereas, for example, for people with an average income it is as much as 14.5%.

The third one. Low-income respondents are fundamentally more likely to find it difficult to answer (20–5.9–11.9%)—they do not believe in a goldfish. Apparently, they intend to shape their own fate with their own hands.

Next, we consider the impact of the place of residence of a modern young man in the Russian Federation on his financial behavior—on variables reflecting the planned use of standard financial tools. For example, a mortgage loan will be more in demand in cities other than metropolises.

Deposits are much more often relevant among people living in a metropolis. That is, the metropolis is characterized by more "lazy", but also more reliable financial behavior strategies.

Other financial tools, for example, mutual funds, leasing, insurance investment, etc. are ultimately more attractive for non-megalopolis (50–69.2%). Moreover, all these are standard financial tools (mutual funds, leasing, insurance investment, etc.).

Hence, people in metropolises and, nominally, in the province are slightly different, which generally reflects objective reality [4–12].

Thus, the research may serve as a basis for a program for developing regional branches of commercial banks of the Russian Federation.

4 Conclusion

The conducted sociological research in the framework of the scientific paper "Institutionalization of financial literacy of the Russian population" is a necessary element in assessing the level of financial literacy of the population of Russia, based on the use of a set of methods to determine the level of financial literacy for developing measures to increase its effectiveness. The indicators of the study base presented in this research reflect the population's perception of financial literacy in 2019 with the aim of improving the institutionalization of the population financial literacy improvement system in the Russian Federation.

The indicated author base for assessing the level of financial literacy of the Russian population can be applied for:

- improving the regulatory framework and editing the planned documents related to the problems of improving the financial literacy of the population;
- adding such target groups as people experiencing certain life difficulties in realizing their rights to financial education to the "road map" and protecting them;
- creating a system of providing free financial assistance to citizens, which is based on institutionalizing the mechanisms of free financial assistance, that is, its normative regulation in the framework of the legislation of the Russian Federation and constituent entities of the Russian Federation)
- implementing measures to enhance the financial literacy improvement strategy management system including by making fuller use of the potential of educational and civil society institutions;
- developing a state program to improve the financial literacy of the population of the Russian Federation based on raising consolidated financing for the development of a financial education system and financial education of the population;
- developing and monitoring by state, financial, public and other non-governmental and private institutions of ethical standards and consumer protection laws during measures to improve financial literacy for the adult population.

The Importance of the Development of Forms and Methods of Stimulating Innovative Activity of Personnel in the Strategic Aspect

Valentina N. Parakhina and Ekaterina I. Alekhina

Abstract *Purpose*: The aim is to assess the impact of various forms of stimulation of innovative activity on the innovative activity of companies in modern conditions of Russia, as well as to determine on this basis the opportunities and directions of innovative development of its economy. As the analysis of activity of business structures has shown, the process of solving the problems of innovative development in reality faces a number of obstacles, which are the result of the lack of effective solutions to stimulate the innovative activity of the personnel of most enterprises. The main objective of the study is to clarify the problems of innovative development and assess the effectiveness of the use of tools to stimulate innovation in the strategic aspect. *Design/methodology/approach*: The main research methods included: analysis of modern concepts of innovative activity, comparative analysis of the practice of innovative activity of a number of regional enterprises, method of systematization, comparative method, questionnaire, methods of quantitative and qualitative data processing. *Findings*: The main result of the study is the conclusion that the most important problem of the development of innovative activity of domestic enterprises is the low level of motivation of innovators, relatively high efficiency of the methods used to stimulate innovative activity of personnel. In our opinion, the problem of innovation management has a structural character, which affects the entire system of strategic innovation management. In recent decades, there have been significant changes in the sphere of entrepreneurship and development of market relations, which gave rise to an increasing level of competition and actualized the problem of innovative development and stimulation of innovative activity in the entire market landscape and the regional environment. This is also due to the toughened conditions of competition, complications in interactions with international partners, etc. The article presents the analysis of innovative activity of a number of regional enterprises, describes the ways of stimulating innovative activity of personnel, suggests the use of tools to stimulate innovative activity of personnel in

1 Introduction

One of the instruments of social and economic policy of the Russian Federation is innovation policy, which is aimed at developing competitive advantages of domestic business in the foreign and domestic markets, as well as stimulating the development of modern technologies and competitive domestic innovative products. Competitiveness of industrial enterprises is largely determined by the stimulation of innovative processes that ensure the introduction of high technologies into the production process, including resource-saving and environmental-saving, increasing the production of high-quality innovative products endowed with the best consumer properties.

Summarizing the trends in the development of innovative enterprises, taking into account the realities of modernity, which is characterized by the trends of rapid information development, it allows us to conclude that there is a new relationship between human and physical capital: human capital is the basis for ensuring economic development [1].

The analysis of the publications showed that the research of modern scientists emphasizes the connection of innovative activity of the enterprise with the personal qualities of managerial employees of business structures. According to a number of authors, innovative readiness for innovations of employees implies the presence of a set of innovative and motivational characteristics [2]. Some scientists express the opinion, based on the analysis of management practices of effective innovation-oriented enterprises, that the set of features of behavior of employees of such companies, which indicate that innovative behavior is a complex phenomenon, which is based on the ability of the employee to realize his creative potential, generation and implementation of new ideas [3].

Despite the current trends, there is an acute shortage of effective technologies for strategic management of innovative activity of personnel and not enough effective development and application of strategic decisions to ensure innovative activity of personnel. In connection with the above, the problem of stimulating innovative

activity of personnel in the strategic aspect is significant for modern science and business, in this connection.

2 Materials and Method

The main research methods included: analysis of modern concepts of innovation, a comparative analysis of the practice of innovation in a number of enterprises in the region, a systematization method, a comparative method, questionnaires, methods of quantitative and qualitative data processing.

The use of methods of comparative analysis of modern concepts and practice of motivation of innovative activity is determined by the following considerations. Despite the fact that at the theoretical level this area of research is highly developed, at the practical level in managing the economy of the region there are many problems that are associated with the unsystematic nature and low influence of the tools and methods used to stimulate innovative activity, which requires their further scientific development.

The analysis showed that the collision with the crisis in the country's economy has generated a new wave of discussions on this issue. It should be noted that the leading role in the process of stimulating innovation is given to the state, which is fully confirmed by the experience of developed countries. At the same time, support for innovation in almost all sectors of the economy is of a diverse financial nature, however, the volume and direction of government spending on innovative development depends on the characteristics of the country, the extent of economic activity, the degree of provision with natural and human resources, and the traditions of state institutions of the country.

The method of systematization and the comparative method of tools and methods of stimulation is necessary to identify effective measures of motivation for innovation. As systematization of world experience has shown, tax incentives are the main measures to stimulate innovation. Comparison with Russian experience allowed us to conclude that in the post-crisis period, the development of tools to stimulate innovation in Russia was determined by the processes of modernization of the Russian economy, carried out against the background of an imbalance between the needs of the innovation sector in Russia, the availability of capital and the possibilities for its effective use.

The state policy of stimulating innovation activity combines the use of direct and indirect methods of stimulation. In the last decade, there has been a transition from direct methods to indirect methods and incentive tools, carried out mainly in the tax, customs and insurance sectors. This process is correlated with the world experience of stimulating innovation.

Questioning methods, quantitative and qualitative data processing were used to identify the attitude of entrepreneurs in the region to various instruments of state innovation stimulation.

3 Results

As a result of the author's research of a number of innovative enterprises of the Stavropol territory, it was concluded that on average, the level of material remuneration at enterprises engaged in innovative activities is higher by 21% than at other enterprises. The system of material incentives usually consists of two parts-salary and bonus (motivational).

The motivational part is calculated for the personal contribution of the employee and the final result of the enterprise.

As a rule, stimulation of personnel to implement innovative activities is carried out in two forms: material and non-material.

The material form of stimulation is based on an increase in wages, the allocation of additional monetary and material remuneration.

Non-material stimulation of the personnel includes encouragement of work of employees for qualitative work, achievement of the set indicators, performance of difficult organizational, production, labor tasks which neither directly, nor indirectly do not influence the level of a salary and other payments. Incentive Methods are integrated into the incentive system itself and imply a set of methodological tools for the implementation of incentives in any form. Despite the fact that, according to some experts, the innovation activity of enterprises largely depends on the leading role of the state (in terms of developing and implementing ways and means for economic incentives for business processes, for example, in the framework of the state innovation policy through the establishment of national priorities, the state's conduct on the market of scientific and technological achievements, etc.), but one of varnishes transparent activity supports innovative initiative is working, or the human factor.

Among the cornerstones of strategic motivation of innovation activity, an important place is occupied by its effective and systematic state support, including the use of direct and indirect methods of its stimulation.

The use of direct methods provides for differentiated investment of budget funds in innovative projects, indirect methods include a set of tax and customs benefits. The number of instruments used at the state level includes:

(1) subsidies that enable enterprises (legal entities) the opportunity to reimburse the costs of the enterprise received as a result of innovation and scientific activities [4];
(2) grants, which involve the gratuitous allocation of funds to legal entities and individuals for their investment in innovative projects, research on the terms of grant-givers [5];
(3) lending to innovative projects is limited and in practice involves the participation of the state through subsidies to provide state guarantees for the obligations of the enterprise. This also includes such a relatively new phenomenon as innovative leasing, venture financing, through which investments in high-risk innovative projects are carried out [6];
(4) the Federal contract system (FCS) and public-private partnership;

(5) the provision of tax and customs privileges to enterprises engaged in innovative activities [7];
(6) financing of projects and programs that have been developed in order to strengthen the interaction and cooperation of all participants in the innovation process;
(7) state measures aimed at ensuring free access to knowledge, including the features of the national innovation system [8];
(8) legislative support for innovation;
(9) other forms of support for innovation activity, including technology parks, venture capital firms, innovation centers, business incubators and so on [9, 10].

The above methods of stimulating innovation are actively used in modern Russia, which in General stimulates the development of innovation activities with varying degrees of efficiency [11, 12].

At the same time, each enterprise has its own innovation policy, which directly depends on the motivation of the management and managers of the enterprise. Despite the government's proposed support for innovation, not all enterprises apply for it. As the analysis of statistical data showed, despite the measures taken by the state, the innovative activity of Russian enterprises has contradictory development trends (Figs. 1, 2 and 3).

As can be seen from the data presented in the chart, the volume of shipped innovative goods, works and services in 2018 compared to 2010 increased significantly-by 3.64 times, this increase occurred against the background of an increase in the total number of shipped goods of own production, works and services performed by own forces, this indicator increased in 2018 compared to 2010 by 2.68 times.

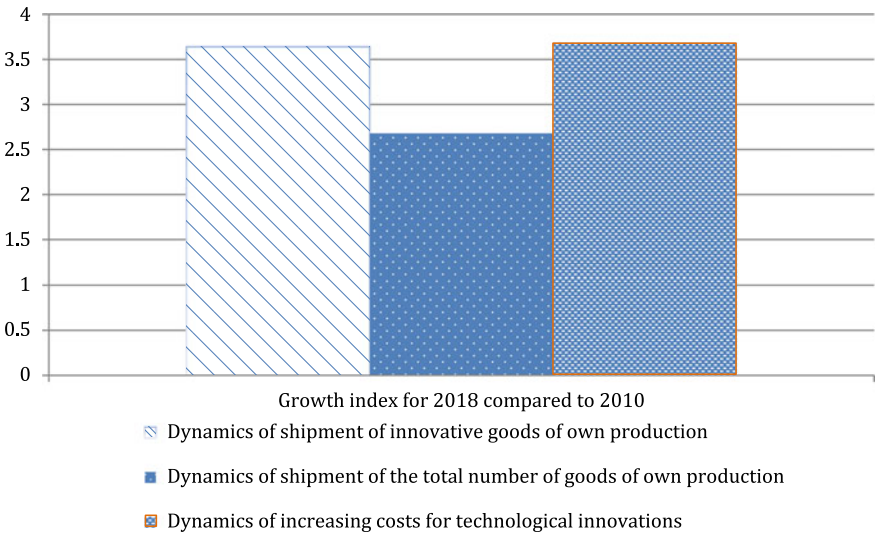

Fig. 1 Main indicators of innovation activity dynamics in Russia

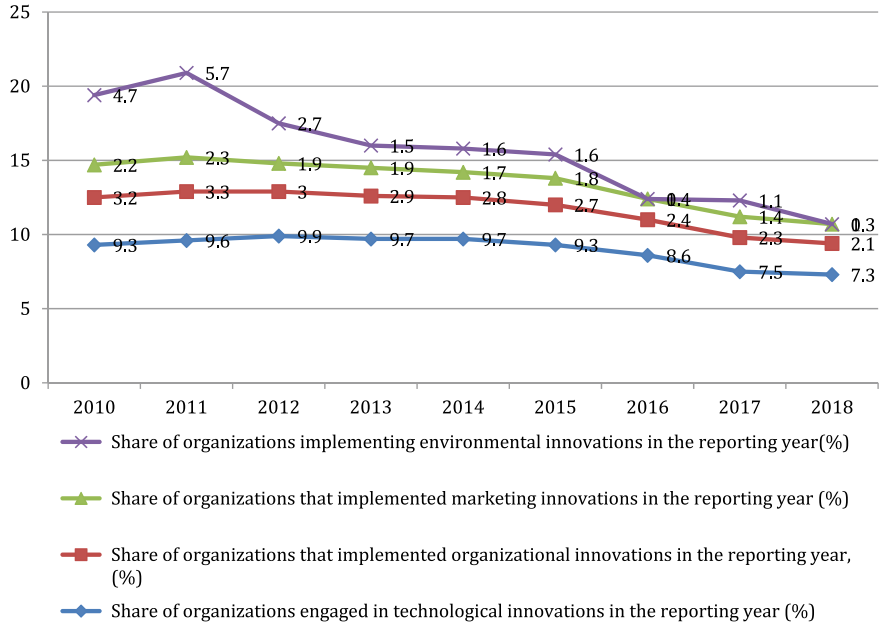

Fig. 2 The share of organizations that carried out innovations (by type of innovation)

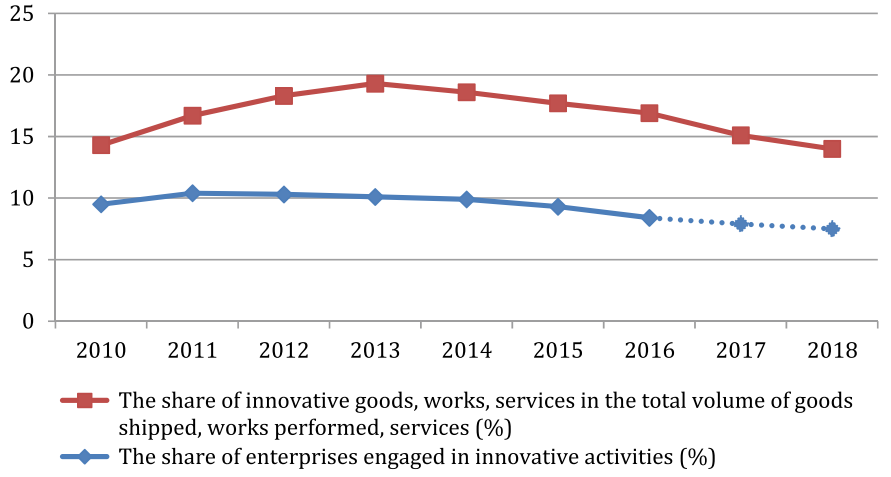

Fig. 3 Innovative activity of organizations

Despite a significant increase in the cost of technological innovation, this indicator increased in 2018 compared to 2010 by 3.68 times, the dynamics of shipped innovative goods, works and services is significantly behind.

According to the data presented graphically (Fig. 2), it is noticeable that the share of organizations engaged in other types of innovative activities is significantly reduced.

Thus, the share of organizations engaged in:

- organizational innovations decreased by 1.1%;
- marketing innovations decreased by 0.9%
- environmental innovations in 2018 is absent, in 2017 there was a decrease of 3.6%.

The General analysis of innovative activity allows to conclude that the tools of stimulation of innovative activity applied at the state level are aimed mainly at promotion of technological innovations mainly at large industrial enterprises [10, 13].

The analysis of the dynamics of innovation activity of enterprises in relation to the dynamics of increasing government spending on innovation suggests a low efficiency of measures used at the state level to stimulate innovation [14, 15].

In General, the analysis of stimulation of innovative activity in modern conditions allows to conclude that at the state level this aspect is given some attention. Thus, a number of programs and resolutions of innovative development have been adopted and approved, which regulate the creation of organizations supporting the innovative activity of enterprises providing information and financial support in the field of innovation. However, the analysis of the tools used by the state to stimulate innovation and innovative development in our country indicates the presence of a number of problematic aspects and needs to develop new directions in order to increase the effectiveness of innovation impact [16] Analysis of the reasons for the decline in innovation activity of Russian enterprises in order to study the reasons for the decline in innovation activity [17, 18, 19], a list of them was selected and ranked, among which were such parameters as:

- bureaucratic barriers;
- unfair attitude on the part of some officials;
- leakage of information providing trade secrets;
- tense socio-political situation in the region, increasing the risk, especially when implementing long-term innovative projects;
- high level of competition in international markets;
- low level of awareness of the majority of small and medium-sized enterprises, not associated with educational centers, involved mainly in trade, services,
- long waiting times for funds for innovative projects;
- low level of motivation of heads of enterprises to conduct innovative activities;
- lack of knowledge about the effectiveness of innovation-active enterprises in a particular area;
- low level of trust in the authorities;

- insufficient information about decisions and regulations in the field of innovative entrepreneurship;
- not the ability to find personnel capable of functioning effectively in the conditions of innovative transformations.

In addition, according to the entrepreneurs themselves, when allocating funds in accordance with state programs, they have to face a lot of bureaucratic red tape, long waiting times for funds, so far in these areas, despite the approval, about 60% of the funds have not been received on the accounts of entrepreneurs.

In recent years, more and more researchers put forward and prove the correctness of the hypothesis about the close connection of innovative activity of the company with the personal qualities of its management personnel. So, according to T. V. Lukyanova and T. A. Alekseeva, the innovation readiness of employees suggests that such a specific set of innovation-motivational characteristics [2]. According to other authors, innovative behavior should be considered a complex phenomenon, which manifests the ability of people to generate and implement new, as well as its willingness to effectively use their creative potential. The above allows to include a subjective motivational factor in the range of problems of development of innovative activity. Weak business motivation contributes to the decrease in the level of innovation, along with the difficulties of their implementation [20].

To support the innovative development of entrepreneurship in the modern period, it is necessary to achieve a harmonious combination of external and internal incentives for innovation.

The procedure for stimulating innovative activity in modern economic conditions should be integrated into the overall structure of the company's economic activity and have a holistic character. The structure of the process of stimulating innovation should reflect consistently all stages of the life cycle of innovation from the emergence of a new idea to its development in production and mass consumption of the results of the innovation activity.

4 Conclusions

With the aim of activization of innovative activity in Russia it is necessary:

- to develop effective tools of stimulation of innovative activity of the personnel (such tools should provide strategic adaptability to modern market conditions and the competitiveness of strategic management through the development of an effective system of staff motivation to innovate);
- to provide formation of legislative and institutional conditions for mass introduction of progressive innovative technologies, and also mass production of high-tech types of industrial production;
- to create system of regulation of innovations at the micro level for ensuring innovative activity of the enterprises.

As shown by the study, the measures used at the state level to stimulate innovation are not effective enough. The main support of the state is carried out without taking into account the impact on the personal qualities of managers and managers of enterprises. Technological innovations are the main object of state attention.

In our opinion, reducing the effectiveness at the state level instrumentation innovation is due to the fact that in modern conditions the special importance in the process of development of measures on stimulation of innovative activity takes on the human factor, including motivation and professional qualities and knowledge of all employees. Without taking into account these features, it is impossible to influence the innovative activity of business.

For system motivating influence on it introduction of the centers of responsibility for innovative activity and programs of increase of innovative competence of management of the enterprises is expedient

Acknowledgments The reported study was funded by RFBR, project number 19-310-90043.

The Development of Civil Society in the Context of Digitalization and Dissociation

Daniel V. Petrosyants, Stanislav P. Mitrakhovich, Igor V. Iushkov, and Evgeniya V. Makhmutova

Abstract The article raises the problem of establishment and further development of modern civil society in Russia, its institutions and possible conciliation of members' interests in the context of the income gap and various reality-reflection psycho-social matrices. The paper also pays much attention to scientific and expert discourse. Analyzing various approaches to assessing the importance of civil society development in the works of Russian and foreign researchers, the authors make an attempt to extrapolate these developments and adjust them to the conditions of modern Russia. The article proves that the problems of poverty and strong socio-economic stratification can be overcome without the development of the civil society institution in modern Russia. The authors provide the findings of the time series of VTsIOM (The All-Russian Public Opinion Research Center) polls by indices of social well-being and the number of publications on poverty issues in the Russian mass media, which show a correlation from 2012 till 2018. From the 4th quarter of 2018, the problem of media poverty is highly discussed and no longer correlates with VTsIOM research.

1 Introduction

The development of civil society in the Russian Federation since the crash of the socialist system has been developing under specific patterns. The dismantlement of the Soviet social state has led to unprecedented scales of inequality and poverty in our country. While underprivileged and most vulnerable strata are falling deeper into credit chains and getting poorer, the richest and high-privileged part of the population is keeping in their hands the country's wealth [1].

Decree of the President of the Russian Federation No. 204 as of May 7, 2018 "On National Goals and Strategic Objectives of the Development of the Russian

Federation until 2024" sets a two-fold cutdown of poverty for the target period as one of the national goals. Our country will have a tough time on the way of poverty cutdown and establishment of social harmony, but this problem must be necessarily mitigated.

In this paper, the authors try to find a relationship between the goal-setting of various social groups of the Russian population and socio-economic development, imperfect civil society and market economy institutions and the inconsistencies of inverse social relationships corresponding to these realities with the conception of the Western democratic model. Having traced and explored the role of civil society in the landmark socio-political events of today, we need to seek patterns and a solution to the problem of social vulnerability and instability in modern circumstances.

2 Methodology

The research methodology is based on general and specialized methods of scientific knowledge: empirical research (data observation, comparison, collection, and examination), current and prospective analysis and synthesis of theoretical and practical material, multiple classification, sociological method, statistical analysis, etc.

The academic literature on the problems of civil society development is enormous and diverse, also because this topic is regarded both from the perspective of social, moral and political philosophy [2, 3], sociology that is associated with economics, political science and cultural studies [4, 5], and directly applied political ideology in specific countries in a certain period. There are many classifications of civil society theory. In the context of identifying the place of civil society in relations with state institutions and business during the time of discussions on the future of "digital democracy/polyarchy" and "digital authoritarianism" (China is often accused of this). The classification of theories on belonging to the so-called L- and M-paradigms is of highest interest. Unlike many historically established analytical frameworks for the study of social thought about civil society, the approach through the L- and M-paradigms can be recognized as one that meets the needs of the time.

These terms were devised by the American political philosopher Adam Seligman, who classified the paradigms of civil society consideration into ones originating from John Locke (L-paradigm) and Charles Montesquieu (M-paradigm). The same partition was revealed in detail by the Canadian philosopher Charles Taylor in his work on ways of civil society arrangement. The L-paradigm describes civil society as one that not resist the state (the latter is so dependent on the society that it does not venture to breach the social contract). The second conception places civil society far out of the state borders and describes their relations as conflict-centered. The M-paradigm was often utilized by politicians of the velvet revolutions, the "Arab spring", etc., as well as the authors of "democratic transit" in political theory, who justified the role of civil society withstanding authoritarian power and large business forms that had nothing in common with democracy.

The "scientific democrats" had troubles on the issue of civil society's role in the "Arab spring". By their example, we just wanted to show that modern civil society organizations that moreover use modern means of communication, including electronic ones (Internet, computer social networks) able to slip decayed authoritarian regimes and build an inclusive democracy instead. However, a regime can be changed only upon the foundation of particular elite alliances that are interested in transformations and that are seeking to gain the highest possible profit under minimization of risks to lose current status. The most important point is that a considerable portion of organizations that rose during the "Arab Spring" turned out to be not representatives of liberal civil society, despite the often-mistaken opinion of external observers, but of local tribalists or religious radicals. And the activity of civil society resulted in not far from always "a binding establishment of future democracy", as believed by transit experts, but on the contrary, the reinforcement of previous-regime state institutions.

The role of new technologies for the self-organization of the public by the "democrats" was interpreted at the socio-theoretical level in the spirit of communicative rationality theory by J. Habermas, which is also another modern concept of civil society derived by M-activists for own ideological synthesis. According to Habermas' opinion, civil society is an area of free communication of independent and autonomous individuals, as well as a combination of business- and state-free "social unions" founded to a large extent voluntarily and spontaneously. Habermas' ideas and his followers A. Arato and J. Cohen were well-received by "theoreticians of regime change through civil society" precisely because they facilitated the intelligent task of entrusting a civil society which is managed by nobody, which appeared spontaneously and without support from any business or actors in power, which is dissatisfied with the current situation, with the entire driving force of the revolution.

According to Habermas' opinion, if civil society is isolated from the state and business as a third sector, then establishing mechanisms of independent regulation through rational communication is both an essential feature and a permanent task to be performed. The Internet and related self-organization tools are the most suitable. Hence, the "scientific democrats" and the Western mainstream liberal press represent an "Arab spring" as the "revolution of Twitter and Facebook." But this interpretation was especially approved by left-wing liberals, socialists, that is, the most devoted adherents of the M-paradigm, who believe civil society to resist even the basic established game rules in the West itself (capitalism, "heterocentrism," utilitarianism, etc.).

The attitudes of radical democrats to the West itself are provided by a famous liberal (left-liberal) American theoretician as Michael Walzer. Talking about radical democracy, he bluntly writes that civil society inevitably exists in the reality of conflict. Walzer supposes that even in the absence of openly harmful institutions civil society will be a ground of competing "causes" ("ideas"), interest groups, companies, parties, even churches, and philanthropic societies. The civil society is driven by combat against inequality, and since radical democrats and left-wing liberals see inequality in everything (for example, Walzer writes a lot about gender inequality and elite domination), the battle against established institutions is inevitable. Walzer calls himself a supporter of "more egalitarian liberalism" assuming the state's duty

to interfere to "set limits on inequality" and "settle conflicts that may arise in civil society." It is obvious that here the "radical democratism" of the M-paradigm starts turning into a demand for a powerful state, which had been initially viewed as a source of danger and possible tyranny in the spirit of Montesquieu's concept.

3 Findings

In addition to the direct efforts of civil society to change regimes or to force them to general liberalization, optimistic theoreticians/democrats (authors supporting the M-paradigm) actively promote theses on the favorable impact of civil society and other points of political and economic processes. Optimism is to keep on regarding civil society as growing now and later from the very bottom; hence the metaphor of grass (grassroots), that is, "grass growing by itself", and at the same time capable of changing lives for the better through pressure on the state. Cooperation with the state, all kinds of co-governance (that is, a type of management that involves those who are managed in the management) are also allowed but under the conditions and on the priority initiative of the civil society itself.

It makes sense to refer to pessimists/authoritarianists mainly the authors from China and Russia (the part of BRICS seen authoritarian by optimists), who in the spirit of the L-paradigm derive rules of governance and all kinds of public participation in accomplishment of policy goals from the primary and directing role of the state. However, there are supporters of new pro-arguments on the L-paradigm from the modern West.

Pessimists believe that civil society will not be able to achieve much success without government support and initiatives, and the overall results for the country will be lower than expected (regarding economic growth, human development performances, engagement of all social groups in the country's success, etc.). Pessimists and optimists are much different in the assessment of the situation in China, Russia or Turkey. Optimists are critical of these countries for a lack of democracy and actually for the direct or indirect engagement of civil society in them in the government system. We will not dwell on the Russian interpretations of its civil society because this topic has already been thoroughly studied. The examples of executing a concise L-paradigm are the operation of the Public Chamber, the All-Russia People's Front, the Open Government (when it has been acting), the Presidential Human Rights Council or various public advocates (ombudsmen) on a wide range of issues. Almost none of the observers call in question the key role of the state in establishing, maintaining the performance and determining the activities of these institutions (as it is formally considered, exactly the institutions of civil society) [6].

The concept of governance well-accepted by optimists from amongst the supporters of the new democracy and the pessimistic authoritarianists has almost a dozen versions: Hybrid governance, public governance, co-governance, asymmetric governance, participatory governance, etc. Good governance has been earlier considered as a separate term in the theory of political governance, but now it is branched

term for all forms of co-governance based on the principle of cooperation and division of powers between state and civil society institutions.

Inclusive economic growth is also associated with additional governability of public policy. The more social groups are engaged in this process, the more inclusive and less probable that the group will remain an outsider without benefiting from the country's economic progress.

An illustrative example of a democratic paradigm in forecasting the prospects of a cooperative economy and inclusive economic growth through co-governance is Joyce Rothschild's concept, who bluntly entitles it "Democracy 2.0." [7]. In his opinion, collectivist-democratic forms of organization have become an alternative to bureaucracy. The author gives various examples of these groups, such as (reciprocal) microcredit agencies, workers' cooperatives, non-governmental organizations, pressure groups, self-help groups, communal and municipal initiatives, social movements and many non-profit organizations in general. The action of these organizations and groups is most obvious within civil society itself, but the opportunities for a deeper involvement of these organizations in municipal and regional governance are already on the surface. According to the author's words, a trend towards the decreased role of the bureaucracy and the transfer of its powers not to just non-governmental, but non-profit agencies is a real thing. This will be "Democracy 2.0" with its formal organization and formal representativity (that embraced far from all the things and all the participants on an equal basis) instead of "Democracy 1.0". Rothschild supposes that consensus decisions in civil organizations of Democracy 2.0 can be made even under their growing scope. Similarly, the author reckons that they can be more representative, including people of different ethnic groups and overcome gender inequality in promoting interests, etc.

Brian Wampler, who develops the concept of Participatory governance, is writing almost like Rothschild, but clarifying that the participatory governance institutions should be ingrained into current bodies of representative democracy [8]. The author discusses an example of the city and municipality of Belo Horizonte in Brazil, where such institutions were just grafted into the current government system. People were elected to the public council, went to hearings and rallies, and, to Wampler, they just represented those groups of the population (through contacts with friends, relatives, neighbors who did not come this time) that were not caught by the traditional representative democracy mechanisms. The supervisory powers of the people participating in co-governance were shared with the official authorities. Many decisions concerning the city and municipality can be made only jointly.

Interestingly, the ability of organizations to deliver people to rallies and meetings is described by the author as a form of power. The very presence of a great number of people at a public event, where government representatives could also be invited to report on the budget or other similar issues, has already played a huge role. To Wampler, government representatives also benefited and received a more true-to-life understanding of population needs. They will be able to develop an appropriate state policy by combining these needs with expert opinion. Many authors of this bias are aggressively promoting suggestions on the development of civil society through a good governance pattern at the international level. In a perfect scenario,

an international civil society should be granted authority to make the governments adopt the type of policies suggested by co-governors from the international level. This scenario is hardly acceptable for those countries that count on the preservation of their sovereignty. It is unlikely that China to change its environmental and Tibet policy under pressure), but this can affect smaller countries. Moreover, some authors propose to execute the concept of good global governance by joining efforts and even institutional frameworks of the UN family with civil society organizations in the narrow sense of the word [9]. Then it will be easier to help the same-ideology structures that cannot get full-fledged co-governance rights in their country [10].

It is striking that, some of the optimists' publications that are prospective at the international level also concern micro-power. Like a school for civil society, for example, narratives about the distribution of power within women's communities that should elaborate self-organization mechanisms, or even extraordinary at first glance space management and rules of behavior in stores, are drawn up [11].

As for agnostics, very few people dare to attack the attitude on essential independence of civil society. However, the same Chinese authors, writing about the involvement of civil society organizations in the co-governance, constantly refer to the principle of maintaining hierarchical relations in socio-political communications. This does not cancel out "participatory" and even "deliberate participatory", that is, the deliberate involvement of an ever-higher number of social groups in solving important issues, for example, environmental and climate policy, but the hierarchy must not be abandoned. Thus, according to Chinese authors, overlapping of the scope of the state, civil society and business responsibilities takes place; but the hierarchy headed by the state as a priority actor does not mean "the wrong civil society", it's just the Chinese model [12]. The Chinese pick up and interpret on their own the ideas on the importance of a local civil society, which, jointly with juxtaposed authorities lay a basis for Chinese civil society in the form of "co-governance of the commune-community" ("a well-structured community of all Chinese citizens") in the country as a whole [13].

The information on patriotic Chinese bloggers smoothly directed by the state to specific platforms like Weibo or WeChat is being provided in the same vein.

For Chinese authors, this means a mechanism of developing "online schools of political participation" and even civil values associated with willingness to participate in the co-governance of their community and disseminate useful information [14]. However, for cynical people, it's nothing other than shifting toward Chinese "digital authoritarianism." [15].

As for the West, whose population generally call themselves liberals, also there are supporters of state priorities in communication with civil society. Thus, in 2016, the group of authors published an article, explored the case with the regulation of shale gas production in Quebec and came to the conclusion that civil society cannot solve similar issues alone. The situation requires more sophisticated mechanisms for cooperation and legitimization of decisions with regard to government interests [16]. However, finally, the government agreed with the standpoint of civil society, which managed to change the opinion of the general public and later one of the authorities.

Nicholas Rose and Peter Miller are among modern Western authors trying to justify the need to depart from the opposition of civil society to the state. From their standpoint, one should avoid focusing on the state, the importance of which is a bit exaggerated (therefore, one should not build a civil society in opposition to the state) [17]. In the authors' view, the key power is now transferred in the field of knowledge and expertise (even "the power of expertise" occurs) that are indispensable for the country. The states are trying to effect distant governance and relying on new technologies. For this purpose, knowledge, and experts are needed, including those existing in civil society. In general, "social government" (understood as "the appropriate government") is deemed by authors as a body that doesn't abuse the power.

It is striking that radical Western democrats who insist on a tough policy to support the minorities, including the policy of identity, may be included in the camp of authoritarians. Its purpose can be defined as the purposeful development of social institutions and the promotion of social processes where justice could be achieved through the evolvement of particular socio-political and cultural identities in society. Besides, in many respects, there still be a contradiction under which the intensification of the identity policy was made by the efforts of civil society institutions, however, its practical execution required (requires) further enhancement of the state and extension of the scope of state influence on social processes and institutions.

From a political point of view, the activities of the State and the Government should be necessarily covered by carefully apportioned messages. The current situation is quite the opposite: the focus is on negative events. In Fig. 1, we presented the dynamic series of data from VCIOM polls on social well-being indices and the number of publications on poverty issues in Russia. Based on the analysis of the series, we can make an assumption that the situation with poverty issues has become more complicated and acute in Russian society since the 4th quarter of 2018. Since the 3rd

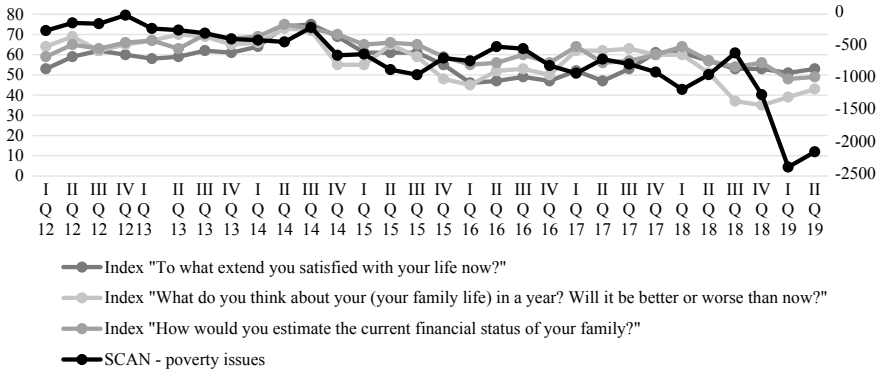

Fig. 1 A comparative analysis of the trend of VCIOM polls' findings on social well-being performances and the number of publications on poverty issues in Russia. *Source* Developed by the authors based on data from SCAN-Interfax [18] and VCIOM [19]

quarter of 2018, there has been a significant increase in the number of publications devoted to poverty and fight against it in the Russian mass media.

Civil society is a combination of public associations and produced social relations between people as members of different-level communities, as well as between communities and political and economic institutions.

Inclusive economic growth is a type of economic growth under which its performances are open to a high possible degree to various social groups and strata, not only in terms of distributing material values but also involving the greatest number of social groups in co-governance and decision making jointly with key government and business actors.

Modern theoreticians of civil society and its role in the development of socio-political and socio-economic co-governance systems (various forms of governance) proceed from the development of the so-called M- and L-paradigms when interpreting the relations between civil society and government authorities. Civil society is regarded either as a multitude of self-organizing communities resisting to real or actual negative and/or selfish intentions of state institutions or businesses or as a large community of people who perceive themselves as a political community of citizens loyal to their state.

The paradigm opposing civil society against the state is often comprehended as fully democratic in contrast to the nominally authoritarian paradigm of involving citizens in co-governance under the leading role of the government [20–22]. Adherents of the M-paradigm especially often blame countries like China, Russia or Turkey in authoritarianism as "taming civil society". In these countries, the involvement of civil society in solving the issues of regional development, inclusive economic growth, environment, and security are made under direct support or control of the government. However, in the West, the nominally loyalist paradigm is still developed in various interpretations of participatory (hybrid, asymmetric) governance, when the regimes called consolidated democracies are offered to become even more democratic and inclusive through the partial transfer of their powers to civil society bodies with which they have a permanent intercommunication. Contractual relations are replaced by cooperation for joint decision making and reciprocal responsibility on the basis of a common value framework. Moreover, the interweaving of government authorities, civil society, and business on a large scale is possible only under a very high level of trust between them and in the state in particular. In this sense, Western proponents of cementing the ties of civil society with their regular state and business are strangely similar to the blamed authoritarians who offer to recognize, justify, and further develop the leading role of the state in societies like in China or Russia.

Today, one of the pressing problems of Russian society is the lack of trust, detachment between society and the authorities, and imbalance of the interests in various social strata. Overcoming poverty and mitigating inequality in society is not only an economic duty but also a social and political one. Distrust in relations between the elites and the rest of society gives rise to "zones of tension" that can be eliminated primarily by establishing social and economic conditions. That's can be a good point of departure for social inequality and poverty to be reduced in our country.

Employment of the Disabled: Economic Feasibility or Social Effect

Dina K. Tanatova and Ivan V. Korolev

Abstract *The purpose of the paper* is to assess the economic and social feasibility of employing people with disabilities. *Design/methodology/approach*: The paper is of an empirical nature. We have used the questionnaire method of sociological surveys. The article has been written on the back of findings of a sociological survey on the theory of social integration. Also, we've applied the concept (approach) of social exclusion/inclusion. *Findings*: Using the obtained empirical data, we've proved that the prevailing trend of employment of disabled people in Russia is not economic feasibility, but the social effect. We've revealed a contradiction between the state's requirement for the employer to comply with the established quotas for the provision of disabled people with jobs (from 2 to 4% of the average payroll for companies with over a hundred employees) and the actions of employers on recruitment of disabled people. *Uniqueness/value*: We've used our own sociological tools that allowed us to get unique empirical findings regarding labor accentuations of disabled people, their job expectations, and their determination to fulfill themselves in the work. The conclusions exhibit the prevailing social nature of the employment of disabled people. It has been established that people with disabilities have paternalistic attitudes and reckon upon government support, but they have incentives for working activity.

1 Introduction

In the modern labor market, there has been a clash of interests of several actors. One of them is the state, which is interested in the development of the economy, provision of the population with jobs by companies and enterprises, decent salary for employees. The second actor is a business that is concerned with its own development, contribution to the economy, economic and social well-being of the state and population. The third actor is employees who expect a high salary and social protection from both on the part of the state and business. Sometimes, the interests of various actors clash. Such a situation may take place when the third actor is employees with disabilities.

Nowadays, in Russia 11 million 266 thousand 830 people with disabilities are entered in the Federal Register of Disabled Persons [1]. This is 7.7% in relation to the total population (146 million 800 thousand people) [2].

The largest group among them is disabled people of group II (5 million 272 thousand 615 people). Three million 466 thousand 195 people are of the working age (16–59 years for men and 16–54 years for women). The share of employed disabled people of working age in the total number of disabled people is 24.3%. Two-thirds of them are disabled people of group III, slightly less than a third—disabled people of group II. Employed disabled people of group I is about 3% [3]. One of the urgent problems associated with the engagement of disabled people is the high unemployment rate. In 2018, the share of unemployed people with disabilities was 17.8%, while the overall unemployment rate in Russia over the same period was much lower (4.8%) [4]. Thus, people with disabilities are a vulnerable group in professional terms. In the opinion of Zaitseva and Khalutornykh ([5], p. 119), the professional isolation of disabled people is contingent on the whole group of factors having legislative, organizational, institutional and infrastructural, social and psychological origin.

The government should engage disabled people in working activities and provide them with extrabudgetary resources. The government also make business actors to hire disabled people and set quota limitations for their employment (Administrative Code of the Russian Federation. Cl. 5.42). But the business does not show interest in creating jobs for disabled people, as far as associate them with additional costs, concern about organizational and psychological problems that may arise during their adaption. Yu.S. Nenakhova notes that “the major and most acute problem which disabled people deal with at work is the lack of workplaces or insufficient equipment of specialized workplaces in the company for the employment of disabled people with regard to the types of disorders” [6]. This statement is proved by the fact that in 2018 only 8 thousand 814 people were employed for quota jobs in Russia [7].

It is impossible to settle this contradiction solely from the perspective of the economic feasibility of engaging disabled people in the working activity. Undoubtedly, the provision of a disabled person with a job will create an additional resource for satisfying his essential needs. An unemployed disabled person cannot financially sustain himself. This problem is solved by his family, society and the government [8]. Granting access to the labor market to a disabled person will ease the financial

burden on his surrounding as well as bring other positive economic effects. We can agree with A. Pokhvoshev, O. Kolesnikova, and Yu. Firsova in that the employment of disabled people is economically advantageous for the government. They believe that "funds invested in the professional education of disabled people are returned as the taxes paid". Also, they stress that "training and subsequent decent employment will allow disabled people to put into life the concept of independence and give them own income regardless of state social welfare like benefits and pensions" [9]. However, the social rehabilitation and adaptation of a disabled person are no less important. Providing disabled people with job helps to solve the problem of social isolation, makes additional sense of life, expands the communication field, and pave personal development ways. The authors take the point of view by Gorina and Kefeli [10] to be true. They argue that through labor a person not only financially sustains himself but also gets the opportunity to apply his abilities and feel like a full-fledged citizen. V.N. Zyazin expresses a similar opinion: "Thanks to employment, people with disabilities feel a part of society to a greater extent, and other social actors are aware of their role" [11].

Along with that, it is noticeable that in developing measures for the employment of disabled persons the government takes for granted that they have incentives for working activity. However, that's not always the case.

For example, referring to the survey by the Department of Labor and Social Protection of Moscow population, the web portal Mercy.ru reports that 39% of disabled people do not want to work [12]. The Committee for Labor and Employment of the Population in St. Petersburg communicates that only one-fifth of unemployed disabled people of working age need a job [13]. That is, we can make an assumption that, on the one hand, disabled people are ready to fulfill themselves in the labor market, but on the other hand, the payment of social benefits creates a snug little job thereby turning them into dependants.

2 Materials and Method

To reveal the problems regarding the employment of disabled people, a sociological analysis laboratory of the Social Studies Department of the Russian State Social University conducted a targeted monitoring sociological survey [14].

The sociological information has been gathered during the competition within the Vth Championship of Professional Skills for People with Disabilities "Abilympics" [15, 16].

The survey was conducted by the questionnaire method. The sample is 1125 surveyed.

The total population of the study (contest participants) is 1332 people.

The surveyed competitors represented 270 Russian cities and localities, including Moscow (171 people), St. Petersburg (49 people), Khabarovsk (29 people), Moscow

Region (28 people), Samara (27 people), Omsk (24 people), Krasnoyarsk (24 people), Kazan (22 people), Perm (18 people), Yekaterinburg (17 people) and other Russian cities (815 people).

There have been surveyed the participants in the championship competing in 62 professional skills. Half of the surveyed are studying at vocational education institutions (39.9% of college students and 11.9% higher education students). About a third of them (29%) are high school students. The fifth part (20.2%) is specialists in various fields.

The proportion of male contestants was 53.5% and female ones—46.5% The average age of the contestants is 21-year old.

Most of the surveyed were people of disability group III (28.9%) and disabled children (22.4%). Disabled surveyed of group II amounted to 18.2%, group I—12.3%, people without a disability group, but with limited health capabilities—18.2%.

Among the surveyed, there were people with hearing impairment (26.9%), vision impairment (17.6%), musculoskeletal disorders (29.2%), with other disease areas (26.2%).

3 Findings

Among the questions there also have been ones concerning the determination of disabled people to raise their economic level through working activity, labor accentuations, etc.

The vast majority of people with disabilities (90%) are ready to work to increase their income. About two-thirds clearly state that (yes), and a quarter doubt (more likely yes than no). Only 3% of surveyed strongly disagree (no) and 7% are more likely to disagree (more likely no than yes).

Incentives for work are higher in more well-to-do groups of disabled people. Among those who regard their income to be extremely low (barely making ends meet), the share of the surveyed who are not determined to work is the highest. We state that poor disabled people do not see a solution to their financial problems in working activity.

Concerning the age, the largest share of people determined to work (depending on the confidence of the answer) is 18–21 years old and 22–25 years old. People with disabilities in the younger age group and 26–29 years old group stronger deny that working activity will help them to increase income.

It can be assumed that a person's unwillingness to work to increase income is associated with a state of health. But the research findings show that only 18.4% of undetermined refer to their state of health. The number of people for whom the pensions and other social benefits are sufficient to meet their needs is far lower (10.3%).

The standpoint of a third of those who undetermined to work is explained by dependant's attitudes. Among them, there are people who just do not want to work (18.8%), as well as ones who believe that the government must sustain disabled people (16.6%).

A lot of surveyed (18.4% of those who undetermined to work) think that the efforts to find work are in vain. They claim that no one will hire a disabled person.

When answering the question "Whether it is easy for a disabled person to find work?", only 14.5% said that there are many suitable jobs and it is easy to find them. A third of surveyed believe that there are jobs, but it is necessary to take efforts to find them. However, almost two-fifths answered that there are no jobs for disabled people or it is hard to find them. Moreover, the disorders of the surveyed do not have much impact on the distribution of job availability estimates.

An estimate of the availability of suitable jobs for a disabled person varies markedly in groups of determined and undetermined to work. Among surveyed who believe that no jobs have been created for them, the proportion of undetermined to work is much higher. Among those who not sure about the availability of suitable jobs, the percent of ones undetermined to work is also increased. This means that for some people with disabilities the lack of jobs is an excuse for their self-exclusion out of work.

However, the labor market attracts the attention of people with disabilities. For them, it is not only a chance of self-sustenance but the satisfaction of higher needs. To the question "Whether you would like to find a job if pensions and social benefits were amounted to 100 thousand rubles", about 70% gave a positive answer. That is, for these people money is not the main driving factor that shapes labor intentions. But about 20% of the surveyed will not work if they can get a high insured income.

In the group of disabled people who are determined to work, the proportion of those who would work, even if they get a decent pension or social benefits is the highest compared to other groups. Obviously, people with different social and labor expectations need various mechanisms of social and labor support.

The findings of an analysis of incentives for the participation of disabled people in the Abilympics professional skill contest prove that they are motivated to be engaged in working activity not only from a financial standpoint. The major incentives for participation in the championship for people with disabilities have an external nature, i.e. they are aimed at exhibiting their own capabilities to others. To win the championship is the major incentive for 56.5% of the contestants. Showing the professional skills to others is an incentive for 31.3% of the contestants. Incentives of professional and communication nature are significant for a lower proportion of surveyed. Networking and job-seeking is the purpose of 16.2% of the contestants, learning about the opportunities of vocational self-fulfillment for people with health limitations and disabilities (13.2%), making friends (15.7%). A relatively small proportion of surveyed is guided by the incentive of spectacular and competitive nature. Fourteen and a half percent of contestants want to see a spectacular performance. A slightly lower share is made up by contestants who take an opportunity of participating in an exciting competition (11.4%).

The consumer-like incentive for participation in the Abilympics is to win prizes and gifts appear among 6.1% of surveyed. We can conclude that the desire to exhibit professional skills and emphasize professional talents is the highest-priority incentive for the participation of disabled people in professional skill contests. Employment is not a key issue for them.

4 Conclusion

The study made it possible to empirically prove that, despite the paternalistic attitudes of disabled people and their expectations of government support, most of them have incentives for work. They are determined to work and increase their income. However, the economic feasibility of employing people with disabilities is not prevailing. The employment for them is, above all, the opportunity to meet their high needs. Even if disabled people have decent pensions or other social benefits, the majority of them are committed to work. Thus, the incentive of disabled people for employment can be stated as a social effect, which will help to broaden communication, apply current skills, self-learn, and make their lives more comfortable.

Differentiation of Education as a Means of Improving the Quality of Technological Education

Zhanna V. Smirnova, Lyubov I. Kutepova, Maxim M. Kutepov, Vasily A. Razorenov, and Maria V. Mukhina

Abstract Development of scientific and technological progress at the present stage requires an increase in knowledge in the field of technology. In recent years, the interest of teachers in educational institutions to apply a differentiated approach to technological education has significantly increased. The application of the differential approach is more and more used in the process of training specialists in technological education. This article provides a theoretical justification for the application of differentiation of education as a means of improving the quality of technological education in a university. The problems of differentiated learning in the process of teaching university students are substantiated. Definition of differentiated teaching is given as a form of organization of the educational process, in which the teacher works with a group of students. Taking into account the presence of any common qualities that are significant for the educational process. An experiment was conducted in the article to determine the effectiveness of the differentiated approach for the educational process. It consists in the qualitative organization of the teacher's pedagogical activity, the development of the content and ways of organizing-multilevel education, which ensures development of the intellectual and personal-potential of all students. Process takes into account the level of education, and their progress towards learning on higher level. The result of applying a differentiated approach in technological education is determined.

Keywords Differentiation of teaching · Technology · Teaching · Quality training · Efficiency

1 Introduction

Modern education system strives to organize the educational process. The focus on the student's learning is highlighted during classes, and individual characteristics of students were taken into account as well. This process is associated with development of scientific and technological progress and expansion of technologies in the field of pedagogy. In this regard, there is a need for differentiation of teaching.

Seleuko G.K., Firsov V.V., Und Inge, Loshnova O.B. and many other teachers were engaged in the problem of differentiated education.

Differentiation ensures the reliability of productive perception by students of the necessary material under study. Since ancient times, they transfer their knowledge, skills and abilities from generation to generation. With each generation more and more knowledge is accumulating [1, 2].

This state of teaching is the basis and engine of scientific and technological progress. Meanwhile, the problem arises of choosing knowledge precisely for the development basis.

Currently, with development of scientific and technological progress, as well as expansion of knowledge in the field of pedagogy. Teachers are faced with the task of introducing modern teaching methods into the educational process.

A differentiated approach, carried out on the basis of technology of multilevel training, allows us to ensure not only the teaching of students-at their chosen level and complexity corresponding to their educational abilities in basic subjects, but also a transition to a higher level in the process of developing their cognitive abilities and personal properties [3].

Thus, such an approach creates the most favorable opportunities for the development of cognitive strength, activity, inclination and talents of each student.

The effectiveness of the differentiated approach in an educational process lies in the qualitative organization of the teacher's pedagogical activity, development of the content and methods of organizing-multilevel education. This ensures development of the intellectual and personal-potential of all students taking into account the level of education, and their progress.

This problem suggests improving the content of educational and methodological education of technology teachers, taking into account the experience gained in the theory and practice of teacher expirence [4, 5].

Differentiating teaching problem in the technological training of future teachers arises from the objective contradiction between the necessary level of technological training and new requirements for a teacher of the educational field "Technology" at school. This is the need and advisability to study the issue of differentiation of education as a means of improving the quality of technological education.

Differentiated teaching is:

- a form of organization of the educational process in which the teacher works with a group of students, compiled taking into account the presence of any common qualities significant for the educational process;
- part of the general didactic system, which provides specialization of the educational process for various groups of students

Differentiation of education (differentiated approach in education) is:

- creation of diverse learning conditions for classes and groups in order to take into account the characteristics of their contingent;
- a complex of methodological, psychological, pedagogical and organizational and managerial measures ensuring the implementation of the learning process [6].

The purpose of differential education: organize the educational process based on the individual characteristics of a person, i.e. at the level of his capabilities and abilities. This gives each student the opportunity to get the maximum knowledge in his abilities and realize his personal potential. This technology allows you to make the learning process more effective [7].

2 Methodology

We conducted an experimental research study for solution of the differentiation problem of technological education at the university,

The solution of problems in the study relied on the use of a set of general scientific and pedagogical methods.

The research methodology includes: philosophical, psychological and pedagogical provisions of personality development, works of domestic and foreign researchers related to the development of a creative personality (Yu. K. Babansky, D. B. Epiphany, B.M. Kedrov, I.Ya. Lerner et al.) [8, 9].

The main objective is the theoretical justification of the differentiated approach effectiveness and preparation of future technology teachers in the module "Creating products from textile materials" [10].

In order to determine the effectiveness research was conducted at the Faculty of Social Management and Technical Services of Minin University. The experiment was attended by 40 students studying in the field of preparation Technology and Economics.

The result of the study was a generalization and systematization of the theoretical foundations of practical results on the differentiation problem of technological education in a university.

An analysis was made of the pedagogical conditions for the organization of differentiated training and implementation of technological processes in the discipline "Creating products from textile materials."

In order to determine the results of using a differentiated approach in educational institutions. The criteria have been developed for the formed technological knowledge and skills according to the groups of educators and the level of technological training [10].

At the end of the study an analysis and processing of the research results was carried out.

3 Results

The main objective of the results and criteria of effectiveness of the differentiated approach of training are:

- improving the effectiveness of education, creating the most profitable education systems that ensure the maximum development of the capabilities and abilities;
- democratization of the educational process, providing students with the freedom to choose elements of the educational process;
- creation of conditions for training and education, optimal individual characteristics and diverse development of students;
- formation and development of individuality, independence and creativity.

A differentiated teaching approach involves various forms of work with students: group, frontal, individual.

Thus, the technology of differentiated teaching is such a construction of a training system in which a student, on the basis of various characteristics, is combined into groups within the audience.

This approach guarantees the assimilation of the basic material by the majority of students, and also provides the opportunity for each student to realize their capabilities and abilities [11].

The use of differentiated tasks is:

- gives the teacher the opportunity to diagnose and monitor the intellectual development;
- taking into account the individual characteristics of students. The teacher can draw up assignments in such a way as to ensure the possibility of each student in the framework of personality-oriented learning;
- systematic implementation of differentiated tasks will give a good result.

Any group in which training differs in any conditions or components of the educational process can be allocated into a special differential group. According to these signs, the following types of differentiated groups can be noted:

- by learning objectives: groups of compensatory training (alignment, correction, pedagogical support), creative, work with the gifted students, pre-university training, mastery of a specialty, etc.;

- on the content of training: in areas with deepening, with a bias, additional educational services, etc.;
- by methods and technologies: groups of developing learning, collective learning method, working on author's methods; computer technology, socio game, etc.;
- by level of training: groups of basic educational standard, advanced level, compensating, adaptive level (alignment, correction, pedagogical support), special, etc.;
- by pace (time) of training: classes (groups) of advanced, accelerated and delayed learning [12].

Differentiation can be distinguished

- according to the sequence of educational material;
- on the structure of educational material;
- by type of educational activity;
- by methods of application of tasks;
- by performance assessment.

After having examined the goals and objectives of a differentiated approach in educational activity. We conducted a study in groups of students in the direction of preparation for Technology and Economics.

The main features of the differentiated approach in the discipline "Creation of products from textile materials" are criterias of the material assimilation level on the subjects under study.

In the classroom in the first place should be considered especially defining the quality of education—these are features of thinking, memory, the ability to design and technical activities, speed, use of tools and devices, knowledge of the laws of the process.

In order to conduct a study of the effectiveness of education differentiation in technological education, we conducted an experiment. Student in the discipline "Technology and Economics" were divided into two groups: one group studied the discipline according to the standard teaching method, and the second group using a differentiated approach [13].

At the technology lesson of textile materials, as well as on other lessons, one of the important components is to control the quality of education. In this regard, we monitored the knowledge of students with test and control tasks, which are more effective ways of checking knowledge of student.

In the experimental group, the selection of tasks was carried out in a differentiated manner, depending on individual abilities and levels of students.

The level of (A)—almond reference level (aimed at distinguishing understanding, learning), such a task is reproductive;

Level (B)—the task is aimed at applying (applying knowledge of situations, tasks—substitutions, tasks with standard situations);

Level (B)—a task of a creative level (aimed at transferring knowledge with use in new situations, analysis, synthesis, tasks—a problem).

Based on these levels of knowledge testing, it is necessary to emphasize the importance of a differentiated approach to the choice of tasks in terms of difficulty for each individual student. Such an approach will contribute to the development of interest in work, independence and self-confidence [14, 15].

One of the points where it is possible to use a differentiated approach in technological training is practical work. The result of the practical work shows the success of the whole lesson in general. The best result of the work performed is the result of an individual and team form of organization of the educational process.

During the study, students worked in groups of 3–4 people with different levels of training.

The process of forming knowledge and skills is a joint activity of a teacher and a student. For the effectiveness of the learning process in the study of subjects of the discipline "Creation of products from textile materials". It is necessary to have a coordinated relationship between the teacher and the student.

The experiment took place in three stages:

The first stage is preparatory (the study and analysis of educational documentation, development of methodological tools for conducting research, study and analysis of student performance before the experiment).

The second stage is formative at this stage, classes were conducted in a standard form (control class) and with elements of differentiated learning (experimental class);

The third stage is the controlling one (this stage was to analyze the results obtained during the experiment).

The purpose of the experiment to verify the improvement of the quality of technological education using a differentiated approach and it is substantiated in Fig. 1.

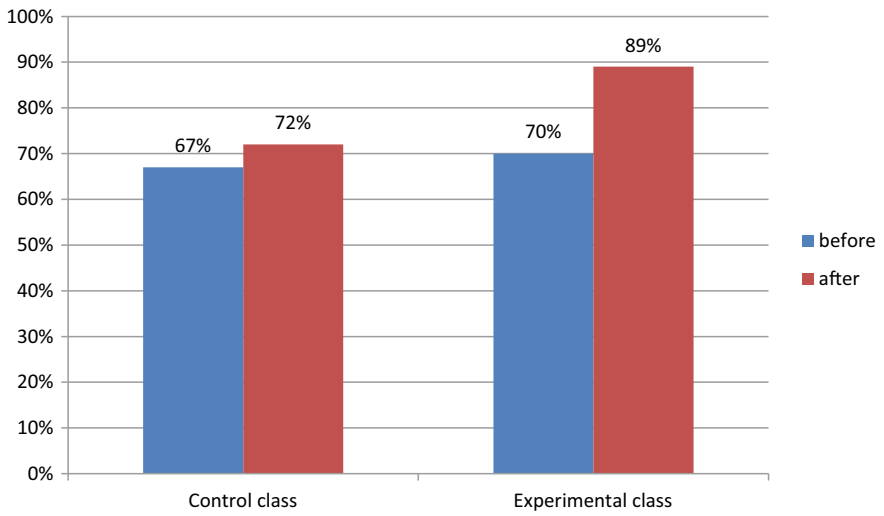

Fig. 1 Application of a differentiated approach in technological education

According to the results, we can draw the following conclusion: in the experimental group, after completion, the level of the quality of training increased according to the results of the control tasks. Control data showed that the use of a differentiated approach in the technological preparation of students is effective and helps to improve the quality of training of technology teachers. The result of the work carried out in the experimental group showed an increase in the quality of knowledge of 89%, and in the control group only a slight improvement of 72%.

Thus, this experiment showed that the use of a differentiated approach in technological education has a positive effect on the development of cognitive activity of students at a university.

Therefore, the application of a differentiated approach to the technological process must be included in the practice of pedagogical activity.

4 Conclusions

A study of a differentiated approach indicates the successful development of cognitive activity and independence of students in a university. The possibility of using it in the educational process to increase intellectual activity of a student.

The result of applying a differentiated approach in technological education:

(1) Development ideas of the theory and practice of the differentiation process are studied. Domestic and foreign views of teachers, various ways of introducing differentiation into the learning process are considered.
(2) The work on differential technology in the classes on the discipline “Creation of products from textile materials” is considered. The use of differentiation tasks enables the maximum assimilation of knowledge for students with different levels of knowledge.

A differentiated approach allows us to develop a higher level of perception, attention, development of memory and technological thinking of university students. This approach increases the activity of students in practical classes, the formation of interest in working methods and the desire for independent thinking.

Information Technologies to Support the Study of Disciplines

Marina L. Gruzdeva, Olga V. Golubeva, Mariya V. Mukhina, Zhanna V. Chaikina, and Olga T. Cherney

Abstract At the Nizhny Novgorod State Pedagogical University named after K. Minin uses information technology to support the educational process. The article considers approaches to creation and testing an information system for supporting the study of one of the curriculum disciplines: the structure of the information system, its content and results of testing the system in the educational process are described. The authors believe that designing the structure of an information learning system should include designing an information system. Development of an interface for working with course data, testing and course management systems, as well as programs simulating examples for each topic of the course. For this reason, the authors described the testing of the developed information system. During which the degree of motivation of students to use the information system in the process of studying was looked at. As well as the level of knowledge of students in control and experimental groups in the studied discipline were checked. Because of the data obtained during testing allow the authors to recommend the implementation of the developed information system to support the study of disciplines.

1 Introduction

The relevance of development and implementation of educational information systems in the educational process is determined by the need for a purposeful organized process. It ensures the education sector with the practice of using information and communication technologies in the training of specialists, informatization of pedagogical activity and management of the educational process.

Speaking about the information technologies for teaching in the educational process. It is natural to assume that the corresponding technologies do not become some kind of add-on to the existing educational system. They are reasonably and harmoniously integrated into the educational process, providing new opportunities for both teachers and students. We consider the features of information technology training in the educational process from the perspective of such integration [1–8].

Introduction of information technology in the education system will make it possible to:

- improvement of the methodology and strategy for content, methods and organizational forms of training that correspond to tasks of developing the student personality in modern conditions of informatization of society;
- creation of methodological training systems focused on the development of the learner's intellectual potential, on the formation of skills to independently acquire knowledge, carry out information-educational, experimental-research activities, various types of independent information processing activities;
- creation and use of computer testing, diagnosing, monitoring and evaluating systems.

2 Research Methods

The aim of the study was to create and implement in the educational process of the university an information system to support the study of the discipline "Modeling of systems".

The RAD methodology was applied during the design and development of the information system: a set of special tools for the rapid development of applied information systems that allow to operate with a specific set of graphical objects which functionally display individual information components of applications.

After analyzing the existing system of education and given the specificity of the information systems used in education. We concluded that the structure we are working on should include:

- information system design;
- development of an interface for working with course data;
- course management system;
- development of programs simulating examples for each topic of the course;
- development of a testing system.

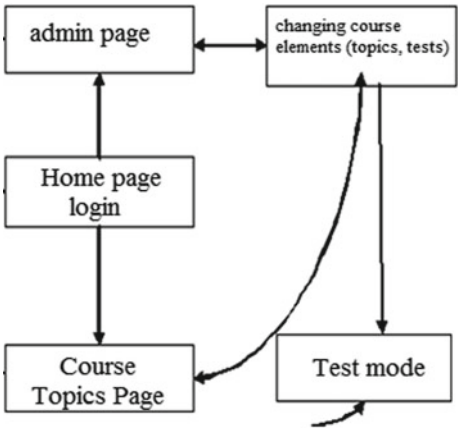

Fig. 1 The structure of the learning management information system

The users are students who log in under their login and password and study the material on the course "Modeling of system". After they are tested in order to control the studied material.

Moreover, the system also contains administrator settings available when logging in with an administrator username and password. The administrator has the ability to customize user lists, as well as manage a list of course topics and test modules (Fig. 1).

In the training information system developed by us, training material is presented for five courses: "System concept", "queuing systems", "dynamic systems", "finite state machines", "probabilistic automata". For each topic, materials are presented on the theoretical part, and the practical part. Test control is implemented (Fig. 2).

After defining the concept of an information system, it was necessary to model the main structural components, their interconnections and processes occurring in our information system. The results of the work are presented in diagrams (Figs. 3 and 4), which allow to depict the necessary system components in accordance with the standards for building information systems.

Let's consider a few basic diagrams:

1. The use case diagram reflects the interaction of system use cases and users. It reflects the requirements of the system from the user's point of view. It helps to analyze requirements, which involves the identification of processes and their formulation.

A customer formulates requirements for the information system. Then developer studies the automated process, while identifying the main characteristics of the future system and makes specifications.

2. The component diagram shows how the model looks at the physical level. It describes system software components and the relationships between them.

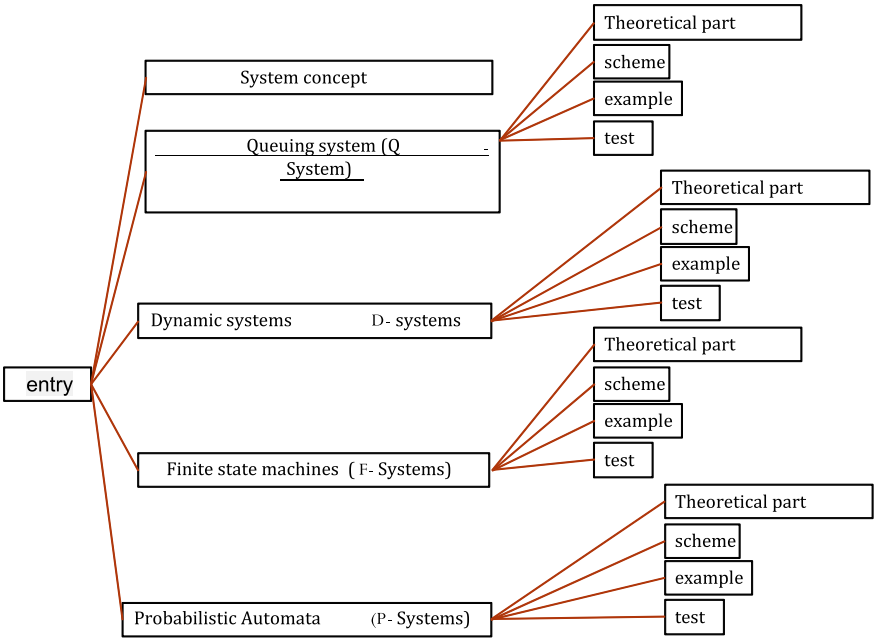

Fig. 2 The structure of the IS on the course "Modeling of systems"

The database of the training information system is a set of text files that contain structured information on the list of users and their learning outcomes, topics of the training course, test suite.

As a result, the theoretical material of the course is presented in the form of hypertext pages—the most convenient form for electronic resources. All chapters of the course have a single design style and are built according to the template: table of contents of the topic in the form of hyperlinks and the text of the chapter with a large number of illustrations, and control questions at the end of each topic (Fig. 5).

The main page contains general information on the course "Modeling of Systems". Each menu item provides detailed information about a particular simulation system.

This is how the menu item "Example" on the topic "Queuing systems (Q-systems)" works (Fig. 6).

In order to model the queuing system, we chose the Delphi language, because it supports object-oriented programming. It is using the tools of which you can easily create a simulation model, which is presenting each of its subsystems as a separate class. In the properties of the class, you can store the parameters of the subsystem, and in the methods—the algorithm of its operation.

The program that we wrote works as follows: We have developed a two-phase three-channel queuing system. In order to simulate the system operation, the user enters the average residence time of the task and the probability of failure. After pressing the "simulate" button, a set of variables appears on the screen, with the

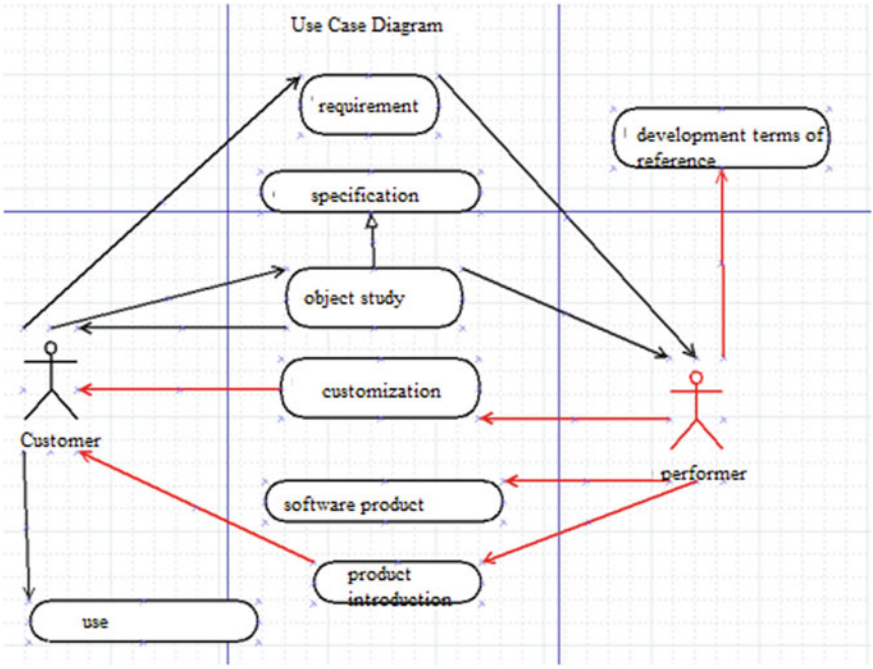

Fig. 3 Case diagram

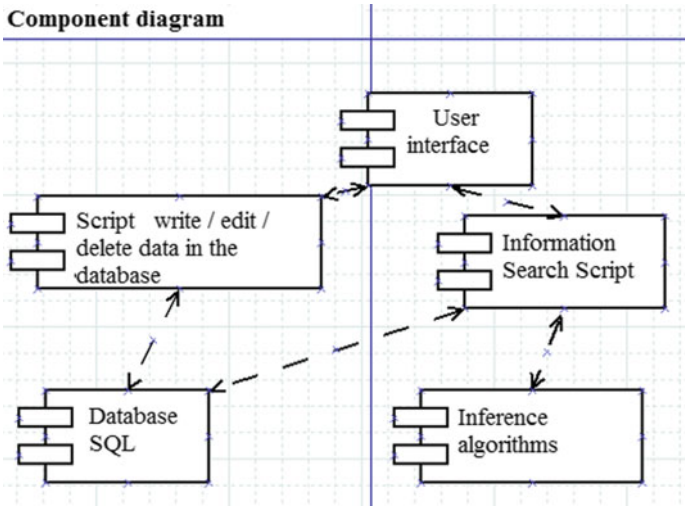

Fig. 4 Component diagram

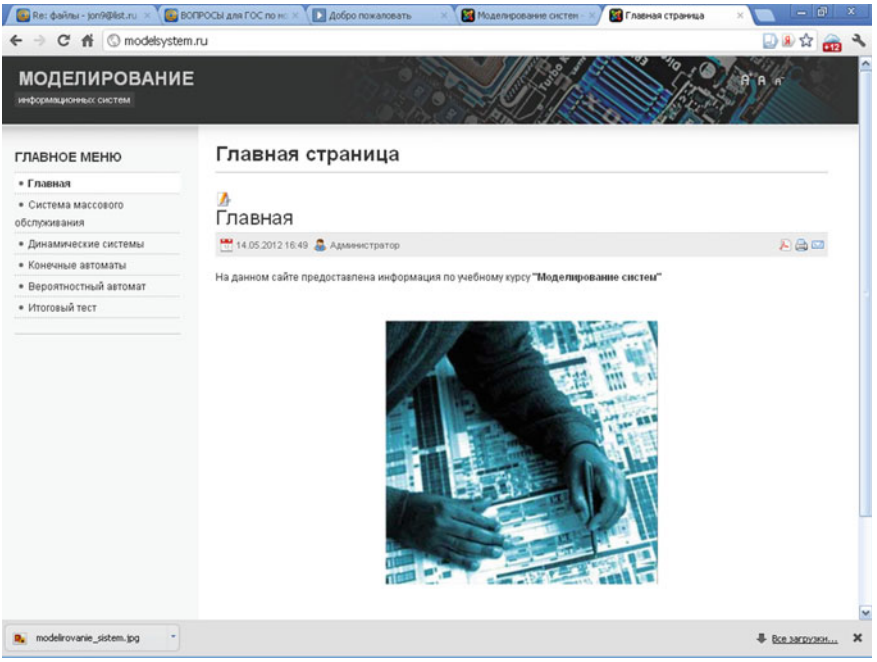

Fig. 5 The main page of the information system

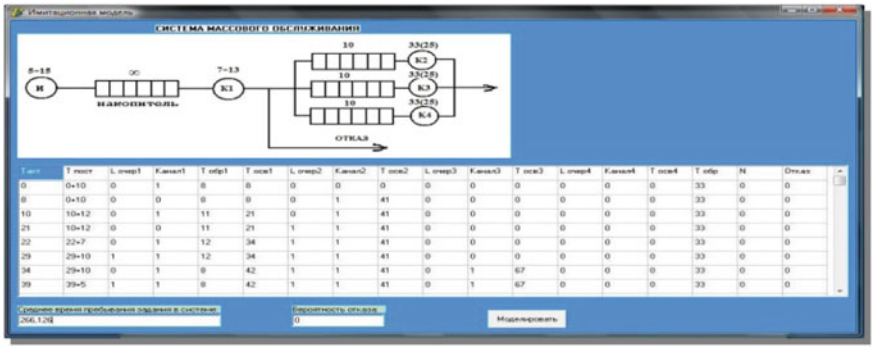

Fig. 6 Queuing system program interface

help of which it is possible to control the process under study, and a set of initial conditions when it is possible to change conditions of a machine experiment. For a complete analysis of the characteristics of functioning. It is necessary to repeatedly reproduce a simulation experiment, while varying the initial data of the problem. In this case, as a result, there is an increase in consuming computer time.

At the end of the development of the information system, we conducted a study on its implementation in the educational process.

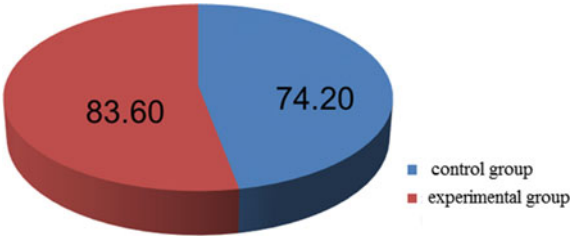

Fig. 7 Level of knowledge of students on discipline "Modeling of systems" by results of intermediate certification

The study involved students of the experimental and control groups enrolled in the direction of preparation 09.03.02 "Information systems and technologies" NGPU named after K. Minin. A total of twenty-three students of the experimental and twenty-two students of the control group.

During testing verified:

- the degree of motivation of students to use the information system in the process of studying;
- the level of knowledge of control and experimental groups on the subject "Modeling of systems".

The motivation of students to use the information system in the process of studying the discipline was evaluated by questioning. Summarizing the data obtained, it should be noted: increasing the interest of students in the study of discipline when using the information system during classes, the degree of independence in the study of sections and topics of the discipline, increasing the motivation to learn while increasing the level of informational, methodological and material and technical support of the educational process.

Furthermore, the level of knowledge of students on the subject "Modeling of systems" was assessed by intermediate certification in accordance with the scoring system used at the university. Figure 7 shows the average score of students in control and experimental groups according to the results of the test-examination session.

3 Results and Discussions

In the development and implementation of the training information system, we adhered to the following principles:

- an iterative (spiral) development model was used, because full completion of work at each stage of the life cycle is not necessary;
- in the process of developing an information system, close interaction with the customer and users of the system was ensured;
- the object model for developing information system software was used;
- development was carried out using visual application development tools;

- testing and development of the project was carried out simultaneously with the development.

Information system developed by us enables the teacher:

- organize active informational interaction between participants of the educational process;
- switch from an explanatory-illustrated way of learning to an activity-oriented one;
- visualize training material;
- provide a wide variety of training;
- increase students' interest in the course.

4 Conclusions

Consequently, the conducted research of development and implementation of the information system in the educational process suggests an increase in the motivation of students to use the information system in the course of studying the discipline and also the level of knowledge.

The data obtained during testing allow us to recommend the implementation of the information system developed by us for the discipline "Modeling of system". As a result, the results obtained indicate the educational effectiveness of the proposed information system and the possibility of its replication in the preparation of students in other disciplines.

Efficiency Improvement of the Use of Labor Resources (on the Example of PAO "GAZ")

Svetlana N. Kuznetsova, Elena P. Kozlova, Victor P. Kuznetsov, Aleksandr A. Shabarov, and Anastasiya D. Efremova

Abstract *Relevance* The use of labor resources represents the most important component of the management system, and the organization of an effective personnel management system. To ensure increased efficiency in the use of labor resources, it is necessary to formulate a personnel policy that gives an exact setting of all goals and objectives, characterizes the principles for the selection, placement and development of personnel. The object of this study was the manufacturing enterprise of PJSC GAZ. The subject is the methodological and practical problems associated with the reproduction of labor resources, the state and search for ways to increase economic efficiency on the example of metallurgical production of PJSC GAZ. The main *objective of the study* is to develop scientifically based proposals to improve the process of reproduction of labor resources, which contribute to the targeted formation, rational distribution and more efficient use of labor resources and increase production efficiency. *Methods* used in the process: methods of economic analysis, statistical methods, graphical method. *Study results* From an economic point of view, an improvement in the personnel management system should provide an increase in efficiency based on sustainable technical and organizational improvement of the organization. Implementation of proposed activities will allow the maximum use and formation of employee's abilities in the company under study, as well as create a favorable psychological atmosphere. These economic and social goals are closely interlinked and ensure the development of PJSC GAZ. *Conclusion* Proposed

measures will increase the stability of the economic component of PJSC GAZ. This should happen through:

- formation of the personnel potential of GAZ PJSC, and a strong personnel reserve;
- increase employee commitment, reducing staff turnover and indirect loss from it;
- increase the desire and interest of employees in achieving corporate goals, significant results, and development of the company;
- increase corporate culture, and labor productivity.

Keywords Efficiency · Labor resources · Personnel policy · Mentoring

JEL Classification J50

1 Introduction

The use of labor resources is the main component of the management system and formation of an effective personnel management system is key for success of any enterprise. In order to ensure the full fulfillment of the tasks assigned to the personnel of organizations. It is necessary to correctly formulate a personnel policy that contains a strategy for personnel work, and also allows to accurately establish all goals and objectives, characterizes the principles for the selection, placement and development of personnel.

Thus, this topic is the relevant because the study of labor resources at PJSC GAZ, allows to determine the necessary actions of increasing the efficiency of their use. This determines the success of the company. The activities of GAZ PJSC are inextricably linked with the production and output of machines from the Gorky Automobile Plant (Avtozavod GAZ LLC) [1].

When making management decisions affecting the efficiency of human resource management, it is possible to increase the economic efficiency of personnel management that will positively affect the entire enterprise. With this measures, it is possible to increase the efficiency of the enterprise to reach a stable level of labor productivity growth of at least 5% per year. In this regard, the management of GAZ PJSC should pursue a targeted personnel policy designed to create a highly professional, motivated workforce, and develop a high corporate culture. The company should try to increase its attractiveness to prospective employees, and help to attract young professionals.

It is necessary to develop new incentive methods, including through the use of various forms of training and staff development. As well as improving the recruitment and adaptation of personnel, which will increase the loyalty and commitment of employees to the company in which they work.

Forms of optimization of labor processes in the enterprise: increasing the proportion of skilled workers among the staff, as well as taking measures to increase the experience of workers, their creative abilities, etc.

The choice of form depends on the company and on its possibilities: how financially independent the corporation is, what tasks and goals the organization faces, the influence of internal and external factors.

1. Creation of a personnel adaptation system as a factor in stimulating new employees in an enterprise [2–4].

The personnel adaptation program includes a set of measures that provide organizational, socio-psychological and professional adaptation of the employee to the new conditions, and provides an organizational chart for the effective implementation of these measures.

Mentoring positively affects the speed of adaptation, the quality of training, loyalty and staff satisfaction.

An effective mentoring system will also help:

- reduce costs and time to reach high labor productivity, achieve a level that meets corporate standards;
- increase the level of professionalism of all personnel;
- reduce staff turnover;
- reduce the risk of burnout of employees;
- increase the effectiveness of training—development and adaptation of personnel;
- increase employee loyalty;
- to insert corporate culture values into the personality of each employee;
- increase HR brand and company popularity in the labor market.

High staff turnover is expensive, especially significant during the probation.

It is easier for a new employee to whom a specific mentor is attached to join a cohesive team. During the probationary period, the mentor will introduce colleagues with whom he will have to interact during the work. The novice will be informed who can be contacted for help in a particular situation. The benevolence of the new team will allow them to quickly adapt to work. As a result, there will be a desire to continue their work here.

Especially, when training a new employee, the company will suffer certain losses that will not pay off soon. But mentoring will help a beginner speed up the process of adaptation and training at the workplace. This will minimize the organization's costs of additional training. An employee, under the strict supervision of a mentor, will try to fulfill his duties efficiently, and do his duties more quickly. He will fix the criteria for the quality of work from the first days of the labor agreement. A friendly team will contribute to motivation and growth of labor productivity.

Workers who have been working at the enterprise for a long time will show how to work by their example. At the same time, they will try to create a spirit of "healthy" competition in order to increase performance.

GAZ PJSC plans to contact Intercon LLC for outsourcing and development of an adaptation system for newly employed employees. In the list of services provided in this area, LLC Interkon offers to carry out the following activities:

- creation of specialized areas of training for new employees;

- development of relevant training materials, taking into account the latest legislative changes;
- testing based on learning outcomes.

The cost of Intercon LLC services for each employee is 3,300 rubles. In general, company will have to pay 27,500 rubles.

The proposed adaptation system is one of the fundamental directions for more successful personnel management in GAZ PJSC. The adaptation system involves a full range of activities, due to which newcomers will quickly cope with stress when entering a new team, and get used to their job responsibilities. It will be easier to adapt to others and so on.

2. The system of professional training and the formation of employees as one of the factors of staff motivation in the organization [5]. The process of professional development of employees is a difficult path, including the development of a training strategy, the rules for planning personal and working time, management of professional growth, and the acquisition of new knowledge or skills.

The company will benefit from the fact that their employees will constantly improve their professional level and outlooks. The latest technologies and developments allow to carry out modernization in production, which will favorably affect the success and business reputation of the organization. The company will become even more attractive not only for its employees, but also for other people who want to work. Since an enterprise that invests additional funds to train its employees looks successful and attractive for doing business.

The proposed professional development system for GAZ PJSC employees is presented in Fig. 1.

The mandatory topics of the non-technical training program at the GAZ PJSC enterprise should be:

- company goals and principles, corporate rules and etiquette, privacy policy;
- effective communication methods, teamwork;
- conflict management skills, etc.

It is planned to use outsourcing, in which GAZ PJSC provides the Consultant or, together with the Consultant, develops training materials and a program for the non-technical training process. The consultant provides training to employees. Moreover, the average cost of conducting non-technical training of personnel in various areas will amount to an average of 1,500 rubles per person.

For certification of workplaces, it is planned to attract an accredited specialized company LLC Intercon, the cost of services of which will be 1,700 rubles per 1 employee.

Based on the training program, it is necessary to make appropriate changes to the personnel training plan and the GAZ PJSC Regulation on the training of personnel.

In addition to the mandatory types of training and professional development of employees at the GAZ PJSC enterprise, it is necessary to create a system of compensation for the costs of training employees. The choice of a training program should

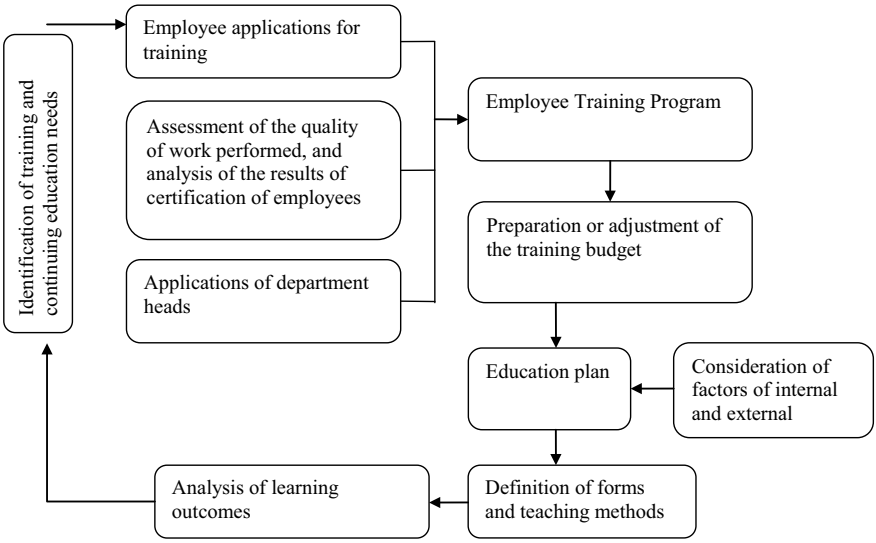

Fig. 1 The system of professional development of GAZ PJSC

be based on the results of certification and analysis of competencies, as well as on the recommendations of the head of the unit.

It should also be noted the need for the employee to work out his training, which was paid by the company.

Management intends to allocate 0.14% of the payroll for material incentives in the form of subsidized training for employees. The possibility of partial or full compensation of training will be a motivating and stimulating factor for personnel. It opens up the opportunity to improve their professional level [6–8].

2 Study Results

The personnel management system of GAZ PJSC is an effective tool requiring constant "adjustment" to the changing external and internal conditions of production and the market in general.

This study allowed us to conclude that when making managerial decisions affecting the effectiveness of personnel management. It is possible to increase the economic efficiency of personnel management, which will positively affect the work of the entire enterprise. In this regard, the management of GAZ PJSC should pursue a targeted personnel policy designed to create a highly professional, motivated workforce, and develop a high corporate culture.

Improving the personnel management system is a necessary condition for the efficient operation of a modern enterprise. The well-coordinated work of the team

and its productive interaction at all stages of production form the basis of a successful business.

The company should strive to increase its attractiveness for promising employees. In every way contribute to the timely rejuvenation of the team, and influx of young personnel. It is necessary to develop new incentive methods, including through the use of various forms of training and staff development. As well as improving the recruitment and adaptation of personnel, which will increase the loyalty and commitment of employees to the company in which they work.

Purposeful work was not carried out to ensure the personnel management system at the enterprise. It happened spontaneously and if earlier work with personnel at GAZ PJSC was limited only to personnel records management. Today the introduction of an effective personnel management system in a company will solve a whole range of tasks, including:

- selection of employees for maximum match to the profiles of vacant posts motivated by effective work;
- planning the need for personnel for the future, which allows timely training of employees or recruit the necessary external specialists
- significantly reduce the period of adaptation of beginners due to the quality of selection;
- already at the selection stage, choose promising employees who are motivated to further career, ready for training and development, which allows them to purposefully invest in talented employees;
- evaluate and certify employees, which allows to obtain reliable and objective results, which are taken into account for the purposes of optimal placement and rotation of the personnel;
- choose and successfully use in practice the most effective personnel management system;
- develop and constantly update an effective system of motivation that meets both the needs of the company's employees and the goals of its management;
- standardize labor and regulate labor relations in such a way as to minimize labor conflicts.

Thus, the operational regulation of the mechanism for increasing the efficiency of the personnel motivation system should be carried out by the heads of PJSC GAZ divisions. They should take into account labor and other control indicators that are exceeded at the end of reporting periods.

According to the results of the first half of 2018, the net profit of the enterprise increased 22 times compared to the same period of 2017 and amounted to 1.9 billion rubles [9].

3 Conclusion

The main strategic objective of GAZ PJSC is to strengthen its position in the market through increasing management efficiency, the quality of work, services, and the quality management system [10, 11] at the enterprise. Thanks to a more modern approach to organizing labor, enterprises participating in the program have become more competitive. The company tripled the volume of orders in 2018. In the plan for 2019—an increase in projects to introduce lean technologies by 1.5 times, about 1, 5 thousand.

As a result, labor productivity already at the first stage of the project implementation increased in some technological areas to 48%, in total, according to the results of 2018, it amounted to 10.5 million rubles per worker, which is 18% higher compared to 2017 with the target of 5% per year. According to the lean manufacturing system and 5C trained 100% of the team. Incomplete production stocks decreased by 10%, on the finished product line, the process flow time decreased by 30% [1].

Until 2021, the company plans to invest about 500 million rubles in order to implement the objectives of this project through the automation of production and the introduction of advanced technologies for production of innovative products. The software which is enabling more efficient use of working time reduces the influence of the "human factor" on product quality due to his readjustment, education, and training of personnel [6–8].

Designing a Professional Education Course Based on Socio-Economic Factors

Svetlana M. Markova, Ekaterina P. Sedykh, and Svetlana A. Tsyplakova

Abstract *The purpose* of the scientific article is to study professional guidance, professional self-determination of a future specialist and the design of a professional educational course. This issue is of particular importance in the context of the development of socio-economic systems, the modern mobility of the professional sphere and the growing requirements for professional activities. *The research* methodology is determined by provisions of the system, competency, activity, design, personality-oriented approaches, and the principles of professional guidance. *Results* As a result the theory and practice of the process of professional guidance and self-determination of an individual, a model for managing the professional and educational course of a future specialist was developed. Particular attention is paid to the stage of professional diagnostics and navigation of schoolchildren or university applicants on the basis of existing methods of professional guidance. As one of the results, a description of the electronic service format of "Personnel constructor". In that case, it ensures management of the personal professional and educational course of the individual during the growing up period, adapting and developing depending on the interests, abilities, individual characteristics, competencies and experience of each person. *The conclusions/recommendations* of the study are determined by the fact that presented model, and higher education organizations can combine their efforts to form the market for applicants and get a more significant effect. At same time general education organizations get access to a consolidated information system of career guidance, interacting in an online consultation system and integrated methodological support. Thus, conditions are created in the region for the formation of sustainable professional communities - specialists of a new formation who want to work actively throughout their careers. They are able to work in the region in order to develop it.

1 Introduction

Professional self-determination, formation and development of a future specialist is a long process. It is ensuring the establishment of a balance between the needs of society in general and individual in particular. The experience of domestic and foreign theory and practice of professional formation of the personality allows us to highlight the most important problems of this process [1]: inconsistency of external circumstances with professional choice; mismatch of expectations from the decision and the process of its implementation; initial understanding of future professional activities.

At the stage of designing a professional educational course serious difficulties arise. Along with the problems of insufficient life vision, professional goals and a professional trajectory. These include: lack of professional skill, insufficiently formed professionally important qualities, lack of readiness for adaptive behavior on the labor market. At the same time, we can observe that in practical activities, factors of individual competence, efficiency, and competitiveness are becoming increasingly important, which determine the importance of a personalized approach to accompanying both professional activities and pre-professional navigation [2, 3].

Traditional approaches using standard methods for assessing and determining readiness for professional activities divided by age and professional categories are insufficient. It requires the use of comprehensive support, which involves not only the development of standard solutions, but also individual diagnostics, consultations, monitoring of professional development and professional retraining throughout all life [4–8].

Under these conditions, the traditional career guidance activities require rethinking, taking into account the need for personal and effective follow-up of specialists of various ages, factors of external environment and challenges of the new era. Interaction with all organizations of the region is required in order to create a unified system of social and pedagogical impact on the formation of the individual's internal need for self-realization of a conscious choice of a specialty relevant in social production. Which is demanded in the labor market, and contributing to the continuous personal development and professional growth of a specialist [9, 10].

Problems of professional self-determination were dealt with by such foreign researchers as A. Maslow, S. Fukuyama, J. Holland et al. In whose writings professional self-determination is considered as a system of tasks faced by a person. It all determined by the requirements of society and representing the process of forming a correspondence between personal preferences and the capabilities of the educational system. The stages of professional development and the problems associated with

them are considered by the authors of the concepts of professional development: E. Ginsberg, D. Super, T. V. Kudryavtsev, E. F. Seer, Y. P. Povarenkov and others. In their work, researchers, as a rule, determine three or four stages of the professional path: in D. Super's concept, these are the stages of growth, research, conservation and recession; E. F. Seer, T. V. Kudryavtsev singled out the emergence of professional intentions, vocational training, entering a profession, the realization of a person in a profession [11]; Y. P. Povarenkov determines the pre-professional development of the personality through the choice of a profession, training, and adaptation; E. Gunzberg in his study identifies the stages of fantasy, hypothetical and realistic stages. As a rule, special attention is paid to the initial stages related to self-determination, choice or formation in a profession ("research stage") and determining the entire personal professional path.

As a result of solving problems at various stages of designing a professional educational course. The authors come to conclusions about the need for systematic work in managing professional guidance, enhancing social partnership of all participants in the process of professional self-determination. As well as the need to organize a lifelong education system throughout life, and widespread use of information and communication technologies in career guidance.

2 Methodology

Choosing a professional path is a long process, which is implemented in a phased passage of the three main stages: 1. development of a personal professional concept, based on a system of settings that describe the idea; 2. professional self-determination (the result of which is the development of a personal attitude to specific professions); 3. professional development (the acquisition of skill in profession, and accumulation of experience). The following are the stages of professional adaptation, development, and maturity. At each stage of a personal professional course, a person needs to make a choice, overcome growth difficulties, and solve specific problems [1].

For the first time, the scientific approach to choosing a profession was applied by Frank Parsons (Smirnova et al. [12]. As part of the activities of the "Bureau for the selection of professions," he developed the basic principle of choosing a profession. This principle including groups of factors (diagnosis of personal and professional qualities); knowledge of requirements and conditions for success (studying the requirements of the profession for a person) in various areas of activity and a reasonable correlation of these two groups of factors (comparing requirements of the profession with the qualities of a person) Smirnova et al. [12].

Our study of activities aimed at professional guidance and the practice of organizing it as a methodological basis is guided by the provisions of systemic, competency, activity, design, personality-oriented approaches [2, 3].

The following principles are distinguished that have a direct impact on the construction of career paths: the principle of personality development in the educational and professional space, the principles of interaction, social mobility, and alternative forecasting.

In the process of development and implementation of the model. Information, diagnostic and advisory, comparative, analytical methods and a method of detailing are used. It requires individual work with each subject in order to build an individual trajectory of professional and personal development.

In this study, we used a comprehensive approach that integrates and creatively transforms the stated approaches and principles, taking into account the need to identify special abilities and personal preferences of a future specialist, monitor professional competencies, continuous and advanced education in order to improve a person's professional level, and master several professions.

3 Results

Based on the considered approaches, we have developed a regional model for managing the professional development of future specialists. Mission: unique professional development of personality throughout life through the definition of varied educational and professional trajectories of personality development.

The model's functionality is provided by a system that consolidates information on personal professional inclinations at all stages of professional formation and development. At the same time providing support and adjustment of professional activity in accordance with an individual professional trajectory and unique professional development of a person throughout life.

The model was developed on the basis of the University of Minin as part of the transformation program of the university into the center of social development of the region.

As part of the general functions of the model—regulatory, informational, managerial, organizational, evaluative. The regulatory function ensures effective coordination of the activities of regional authorities, and it is increasing their responsibility in the field of development and efficient use of human resources.

The information function ensures that all participants are provided with the necessary information about the professions that interest them, and about requirements for personal and professional qualities.

The managerial function contributes to the rational organization of decision-making activities with the aim of planning processes and managing them in development, implementation and execution of a set of measures for professional diagnostics and professional orientation in the region.

The organizational function regulates the process of distribution of duties and coordination of teachers, psychologists, educational organizations, representatives of regional authorities to support activities of vocational guidance, professional development and professional support of a person throughout life.

The evaluation function provides a uniform interpretation of measurements, qualitative and quantitative estimates, forecasts, the quality of the results achieved in the field of professional diagnostics and professional orientation.

In the center of the model are the processes of formation and management of personal professional development of a person. From the moment of choosing a professional concept until the moment of attaining the status of a mentor, and implemented in the context of a strategic plan for the development of the region.

The formation of a professional concept at school age is the result of the integrated impact of various social institutions that provide assistance in choosing professional activities taking into account individual personality characteristics [13].

The goal of personal educational and career paths is to anticipate the desired results, the prospects for personal development. Taking into account directions and scope of the economic development of the residence region. At the stage of career guidance of applicants are taken into account: directions of strategic development of the region, and availability of promising vacancies. The range of ongoing regional educational programs of vocational training institutions for the realization of the possibility of obtaining high-quality vocational education and further employment in their specialty.

Psychological and pedagogical support taking into account the results of training, professional successes, additional education (portfolio), as well as forecasts for the development of the regional labor market and the socio-economic situation. With recommendations for adjusting professional plans, ways, and means of solving negative phenomena and processes of professional development.

Introduction of a model for managing the professional and educational course of future specialists involves the implementation of the following processes [2, 3]:

- development of diagnostic tools for researching the level of professional development of a person;
- development of a diagnostic complex for express diagnostics of the university applicant's potential
- development and implementation of IT-services in the format of "Personnel constructor" and organization of focus group on its basis;
- development of the service "Student's personal cabinet" and its integration with "Personnel constructor";
- formation of a personnel office, and the main information base of which is information about regional employers and vacancies;
- integration of the "Personnel constructor" with the service of postgraduate support;
- commissioning of the integrated service and its maintenance.

For all processes, scientific-methodological, organizational, managerial, financial and economic support are assumed.

A design of the trajectories of the course of an individual is determined by the following processes [11]:

- actualization of the need for professional development;

- analysis of your own educational course;
- forecasting future professional activities;
- monitoring educational course;
- compiling a portfolio of professional achievements.

As a result of the model presented by us:

- an increase in the quality of life of the region's population on the basis of improving the quality of professional activity and the growth of professional development potential of each specialist working in the region;
- an increase in the quality of the regional system of professional education, including online education, and the quality indicators of educational organizations in the region;
- development of a regional system of fundamental research;
- increase in the efficiency of the region's economy as a whole.

The introduction of the model will expand career guidance among middle school students, and in the future among elementary school students, while qualitatively changing not only the system for diagnosing schoolchildren's abilities, but also the system of methodological and consulting work on the choice of professional guidelines, development of a professional concept and choice of profession. Implementation of the model will also expand boundaries of post-graduate support graduates by transforming the activity of continuous professional and personal development experts and formation of a system of mentoring.

The basis of the model of management is a set of information services that ensure the growth of efficiency of personal professional activity, operational analysis and correction of professional trajectory of personality taking into account the peculiarities of personal development and strategic regional development [2, 3, 10].

As a key service, we offer an open regional electronic service in the format "Personnel constructor", providing management of personal professional and educational courses during professional development, professional adaptation and development depending on the interests, abilities, individual characteristics, competencies and experience. Our service is focused on 3 user groups: schoolchildren (applicants), students, graduates (young specialists) of the region [2, 3, 14].

For applicants, the service provides the construction of an individual educational trajectory depending on the professional suitability for a particular profession (identified by the results of express diagnostics in middle and high school): selection of subjects for passing the exam, a list of resources for preparation for the exam, a list of regional educational institutions of vocational education and educational programs [2, 3, 14].

The service will offer students of regional universities additional opportunities on the basis of integration with the electronic information and educational environment of the selected regional university: electronic courses, schedule of classes, choice of options for obtaining additional competencies [2, 3, 14].

An introduction of a model for managing the professional development of future specialists was carried out in stages for various age categories. The experiment was

attended by high school students and university entrants, senior students, young specialists. In the process of testing, the following results were obtained:

Implementation of diagnostic tools allowed to increase the proportion of entrants to make their choice on the basis of a conscious desire for self-realization in the future profession (Fig. 1).

At Minin University in order to accompany students in the educational process, based on the design of individual professional trajectories. Analysis gave a number of social effects, allowing easy adaptation to predict a future professional and to reduce the percentage of graduation characteristic during the first three years for graduates of pedagogical universities. In particular, we recorded a change in students' attitudes toward future professional activity. The material interest, which prevailed at the beginning of the experiment began to be replaced by an interest in future work as a way of self-realization (Fig. 2).

We also noted an increase in the prestige of the teaching profession: more than 78% of senior students noted high social prestige and the importance of pedagogical work (Fig. 3).

Graduates of universities in the future will be offered support of professional adaptation and construction of individual career trajectories on the basis of integration with the subsystem of postgraduate support [2, 3, 14].

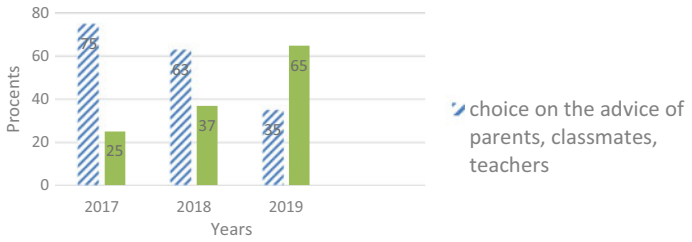

Fig. 1 Justification of the choice of future profession by applicants

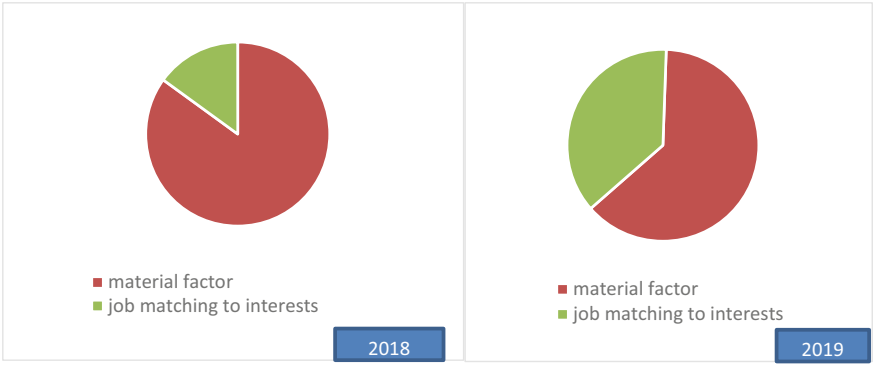

Fig. 2 Main motives for employing graduates

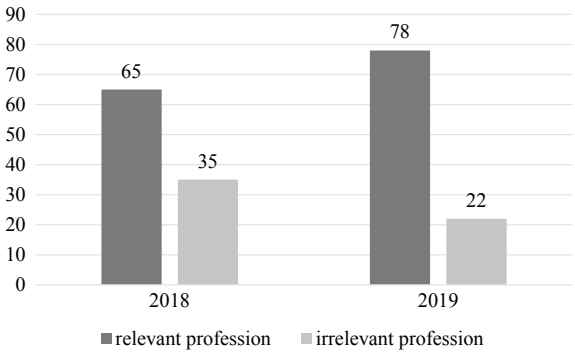

Fig. 3 Prestigiousness of the teaching profession

4 Conclusions/Recommendations

Thus, the model for managing the professional and educational course of future specialists involves comprehensive support for professional self-determination, professional implementation, career growth, personal development and personal success. It is ensuring: pre-professional self-determination (identification of special abilities and interests) based on the results of work with groups of students in grades 8–9 and 10–11; pre-professional development and monitoring (conducting testing at least once a year, providing individual recommendations of consultants); building an individual course of professional and personal development in the learning process (a freshman has a ready-made individual route sheet of professional and personal growth); monitoring of professional adaptation and professional activity (accompaniment of a specialist portfolio); individual accompaniment and development of professional activity (organization of consultations, seminars, creation and supporting the activities of professional associations); creating a mentoring system.

Realization of the model provides professional support for specialists employed in regional organizations and having the necessary professional competence. On the whole, this ensures an increase in the quality of professional education, the efficiency of the duration of an active professional life of the population of the region, and helps to improve the economic, social, and demographic situation in the region [2, 3].

Digital Technologies as a Tool for the Academic Competencies Formation

Leonid V. Dudnik, Tatyana S. Putilovskaya, and Svetlana V. Firsova

Abstract This article is devoted to the analysis of the experience of using digital computer technologies and the principles underlying them in the system of higher education for the formation of academic competencies. The authors consider competencies in the area of abstracting and annotating texts in a foreign language, creating the basis for preparing a future specialist who is able to carry out professional and scientific activities, conduct research and present its results to the scientific community. Having considered the features of summarizing and annotating as types of verbal-communicative activity, the authors present the principles of constructing their competence-activity model, which was the foundation for developing a method of verbal action algorithms that uses the principle of phased (step-by-step) action, as a result of which the student creates a verbal-communicative product in the form of a written or oral text (abstract, abstract, report). For this, a so-called step-by-step instruction for students is developed, in which a certain sequence of verbal actions is proposed to achieve the goal. On the one hand, a step-by-step instruction is based on the principle of learning action algorithms. On the other hand, it contributes to the formation of the student's strategic relationship to his own educational and cognitive activities. Reliance on the using of strategic thinking and the selection of optimal strategies for verbal behavior is manifested in the ability to provide comprehensive planning and organization of one's own activity, its full implementation, objective assessment and correction of the products of this activity. The authors emphasize the advantages of using the verbal action algorithm for teaching bachelors, masters and postgraduate students and refer to the feedback of teachers and students' assessments obtained as a result of the questionnaire, which allows us to conclude that the

1 Introduction

The main request made by society for higher education today is to prepare graduates who will become successful specialists in their chosen field of activity.

Due to the fact that the role of science in the modern world is steadily increasing, and universities play the role of educational organizations and the mission of research centers, the State University of Management pays special attention to the formation of students' academic competencies, which will serve as the basis for subsequent research activities of graduates. Its success largely depends on the degree to which students possess academic competencies when working with foreign sources of information.

The purpose of this article is to consider the essence of academic competencies related to reading and further logical and semantic processing of a text with the aim of reviewing and annotating it, and to show how modern information technologies can optimize the processes of abstract activity, the essence of which is practically unchanged, but the implementation method and mechanisms are improved in principle.

2 Methodology

This study is based on the methods of scientific analysis of the essence of such an important verbal-communicative competence as the ability to write abstracts and annotations. This competence correlates with professionally-communicative activity, which is realized in the processes of professional and scientific communication. The starting point for us is the competency-based approach and the theory of speech activity developed in the already classic works of Russian psychologists [1, 2].

Any activity that, as you know, is aimed at achieving a specific goal and is carried out with the help of subjectively conscious actions, is decomposable into separate actions and operations. If certain skills are required to perform actions, then skills are required to complete operations. They are skills and abilities that form the basis of competencies, the possession of which is a prerequisite for the implementation of any activity and the creation of its product.

In terms of the theory of activity, academic competencies are the knowledge, abilities and skills necessary to carry out actions to create various communication products in a foreign or native language in written and oral form. A specific set of knowledge, abilities and skills creates a certain type of product of scientific activity that has its own competency model [3].

In the modern information space based on knowledge, there are two special types of academic competencies. One of them is necessary for the search, analysis and evaluation of scientific information contained, including in foreign language texts, and the second is used to create fundamentally new communicative products based on this information. Accordingly, two different types of communicative products are distinguished [4]. On the one hand, these are abstracts and annotations related to the processing of information. On the other hand, these are scientific articles, reports at scientific conferences and lectures based on the creation of their own communicative products in written or oral form that meet the rules and standards of the scientific style of speech [5, 6]. All of the listed products of communicative-professional and communicative-scientific activities are examples of the academic text [7, 8]. Both groups of competencies, with help of which these types of products are formed, belong to the category of academic, especially in demand today in the paradigm of higher education.

From an educational point of view, abstracts are a summary of the content of the referenced text as a result of complex analytical and synthetic information processing activities. The basis of the abstract is the transformation of information from a position of significance and meaningful-textual compression of the text, which are its main mechanisms and are carried out in accordance with certain requirements and rules [9, 10].

From the didactic point of view, training in such complex and complex activities as writing a scientific article, preparing a report at a scientific conference or lecture is based on skills formed in the process of summarizing and annotating [11]. Training in academic competencies in the field of scientific and professional activity begins with students mastering the skills of building an oral abstract retelling of a text, preparing an abstract translation of a foreign language text, writing a summary of the text read (summary), and preparing an abstract.

Therefore, abstracting and annotation as specific types of activity is given a lot of attention in university programs for the preparation of bachelors, masters and graduate students in a foreign language.

Consideration of abstract activities as the sequential implementation of interconnected abstract activities focused on the translation of the main content of the referenced text in Russian or a foreign language has a great didactic importance and allows us to develop a competency-based model of abstracting.

There is a main competence in it, which is associated with abstracting the text as a whole can be represented as a set of individual subcompetencies, and they, in turn, are realized through a specific nomenclature of abstract actions.

The existence of two interrelated aspects of abstract activity allows us to say that, from the point of view of the communicative orientation, abstract actions can be

divided into two types: (1) actions for perceiving and comprehending the content of the referenced text and (2) actions for compiling an abstract of this text.

Accordingly, academic competencies can also be divided into two types: (1) search-analytical and (2) constructive-synthetic, each of which has its own competence-activity model.

Search and analytic competencies include:

- the ability to recognize lexical, grammatical and stylistic meanings, determine the meaning of unfamiliar words by context and the meaning of a sentence;
- the ability to analyze information, differentiate basic and secondary information, assess the importance of information;
- the ability to search for basic information of the referenced text;
- the ability to determine the logical and semantic structure of the refereed text;
- the ability to determine the type and basic thought of a paragraph;
- the ability to determine the author's viewpoint on the rendered text;
- the ability to perform meaningful compression of the referenced text;
- the ability to predict the results of their actions, to relate the decisions made to the final product of their activity.

Structural and synthetic academic competencies include the following abilities:

- the ability to correctly arrange the bibliographic data of an article;
- the ability to clearly identify and denote the main topic/problem and main idea(s) of the referenced text;
- the ability to identify and articulate clearly the statements revealing the main topic or the ways of solving the main problem;
- the ability to summarize information;
- the ability to express the content of an abstract in a strict logical sequence;
- the ability to ensure integrity and coherence of the abstract;
- the ability to convey the author's attitude to the subject of speech in the abstract;
- the ability to preserve the scientific style of the referenced text, to use phrases characteristic of the abstracts;
- ability to make references to the author of the referenced text or the text itself;
- ability to follow the rules of written/oral speech.

The construction of a competence-activity model of each of the two groups of academic competencies is the basis for building a unified model of training in abstracting and annotation. The next step in working with models is isolating in the structure of each of the above subcompetencies the totality of verbal-communicative actions that make up every aspect of abstract activity. The ability to analyze information and evaluate the degree of its significance, for example, can be represented as a sequence of actions correlated with certain skills:

1. read the text with a view to a general understanding of the read and the main idea of the text;
2. read the text in order to search for words whose meaning you need to look in the dictionary;

3. read the text paragraph by paragraph in order to highlight the main idea (key idea) of each paragraph;
4. build the predicative structure of each paragraph in which the predicates of the first, second, third, etc. are highlighted. order in accordance with the methodology developed back in the 60s of the last century [12];
5. determine the degree of significance of information at each level and find keywords for information at each level;
6. evaluate the degree of importance of information by the criterion of proximity to the main idea of the whole text.

The degree of fragmentation of the description of a set of actions depends on the level of student's communicative competence, the number of hours provided for in the training program, etc. The didactic meaning of compiling such a model lies in the fact that it becomes a roadmap for the learning process, and the mastery of the activity itself occurs gradually, step by step, moving from one mastered action to another. The construction of such a model is based on the algorithmization of verbal actions, i.e. development of a strict and logical sequence of actions necessary to solve each problem.

In practical terms, the verbalization algorithm is implemented through the development and application of step-by-step instructions for students. In them, all planned verbal actions are arranged in that logical sequence, which allows you optimally and in the shortest possible time to achieve the desired result, i.e. master a certain verbal skill. This technique has a number of advantages. Firstly, every step taken by a student becomes an object of analysis and awareness, which increases the speed and quality of training. Secondly, reliance on algorithmization, which is associated with computer programming, creates a positive background for achieving the result of verbal activity.

Thirdly, such a step-by-step scheme of developing skills is very convenient for working on-line, when each step of the student is under the supervision of a teacher, which minimizes the risk of erroneous actions.

In order for each completed action to be complete and informed, the student needs to have an understanding of the operational structure of the actions and have certain skills for their implementation. So, for example, the search for the basic information of the referenced text can be carried out at the level of sentences and paragraphs [10].

In the first case, indicators of important information can be language tools that students need to be introduced to. In the second case, the search for essential information is carried out by finding the key sentence in it, which expresses the main idea of the paragraph (topic sentence). When highlighting the main idea of each paragraph of the text, we get a hierarchy of meanings located in a certain logical sequence and transmitting the basic information of the whole text. The hierarchy of meanings will also provide a clear idea of the meaningful structure of the text. Only after considering the operational structure of all abstract actions, students master the methods of their implementation, which is a necessary condition for an adequate understanding of the abstracted text and high-quality compilation of the abstract.

Digital, computer, and information and communication teaching technologies that receive a lot of attention in domestic research [13–15], can significantly change the nature and methods of implementing activities such as abstracting and annotation. Modern technologies penetrate so deeply into our consciousness and verbal behavior that provides professional-scientific communication that we often begin to liken the model for the formation of academic competencies of the computer programming model. An example of this is the verbal action algorithm, which we are currently testing on training programs for bachelors, masters, and graduate students. Let us dwell briefly on the main results of this work.

3 Results

Speaking about the first results of the tested methodology of verbal actions algorithms and the use of step-by-step instructions as a way of teaching abstracting and annotation, we note that students must have perfect knowledge of academic competencies. The level of their development determines the student's scientific thinking system, the ability to work with large volumes of information, systematize and analyze it, and produce the finished product in a specific format. All this requires a high level of development of critical thinking, i.e. the ability to soberly evaluate any information, highlight the meaning-forming and filter out the excess, which determines the ability to conduct independent scientific research even at the undergraduate level and improve it in the future.

It's noteworthy that it is during the study of a foreign language that students of all categories have the opportunity to form professional academic competencies, and in this regard, the study of a foreign language in higher education goes far beyond purely language training. The using of computer, digital and information technologies takes the process of forming academic competencies to a new level [16].

An analysis of the results of applying the verbal action algorithm for teaching abstracting and annotation allows us to draw some conclusions that are based, on the one hand, on the assessment of the first learning outcomes noted by teachers, and, on the other hand, on a survey of students undergoing undergraduate, graduate and graduate school.

So, teachers note the following positive trends:

1. The methodology of verbal action algorithms allows spending less contact hours explaining the essence of abstracting and annotation and the characteristics of the products of these activities and spending more time developing practical skills.
2. A substantial part of the work is transferred from class to independent work, which leads to a more conscious attitude of students to the implementation of all types of activities.

3. The methodology of verbal action algorithms allows implementing a step-by-step approach to learning and ensures that none of the important steps are lost during work.
4. The proposed methodology is well combined with the principle of forming a strategic attitude to one's own activity, developed within the framework of the pan-European concept of language teaching, in which strategies are considered more important components of verbal and communicative activity than skills [17].
5. The student gets the opportunity to independently plan, implement, evaluate and correct the activity itself and its products, using the methodology of verbal action algorithms in combination with relying on their own strategic competence (abstracts, annotations, etc.).
6. The technique allows verbal actions to be performed step by step, obtaining as a result of each step a fragment of the common product, which is formed into a single verbal-communicative product from separately prepared fragments at the end of the cycle.
7. The methodology of verbal actions algorithms helps students to complete all tasks on the computer, having access to on-line dictionaries, reference books and other resources, and consult, if it's necessary, with the teacher on-line, in remote form, using various platforms, programs and even messengers.
8. The final product of the activity implemented with the help of the proposed methodology turns out to be better, because each individual element becomes an object of attention, thought and awareness.
9. The proposed methodology can be the basis for the development of on-line courses and even on-line lectures, in which it's possible to regulate the degree of fragmentation of step-by-step actions. It's in this mode that students can themselves regulate where, when, and how many training steps they need to complete in order to assimilate the material and obtain the necessary verbal product.
10. Using the methodology of verbal action algorithms changes the teacher's function in the educational process, turning him into a consultant or curator, directing and correcting the cognitive activity of students and the process of building competencies.

Students, among whom the survey was conducted, note other advantages:

1. A step-by-step instruction, which includes all the steps that must be performed sequentially to prepare essays and abstracts, is very convenient to use and significantly speeds up the process of doing work, although, at first glance, it seems to students very labor intensive and time-consuming.
2. The sequence of actions proposed in the instruction is logical and doesn't contradict students' ideas about how it should be implemented.
3. All work is performed on the computer in Microsoft Office programs that allow formatting, editing, verifying and correcting the text of the verbal product.
4. It's conveniently that all the necessary reference material is freely available on the Internet.

5. Masters and graduate students, for whom the formation of academic competencies is a priority of the educational process, especially note the use of step-by-step instructions for finding information, articles, monographs, conference abstracts, etc. in a foreign language. This refers to all the material from which students choose texts for abstracting and annotation in accordance with their area of study, professional and scientific interests, level of language proficiency and other criteria.
6. All categories of students noted that foreign language classes have become more useful and personally meaningful for them, and although for many of them a relatively low level of language proficiency (below B1 on the pan-European level scale) is a problem, they can easily cope with the tasks on the preparation of essays and annotations.

4 Conclusions

In the era of the rapid development of digital, information and communication and computer technologies, the formation of relevant academic competencies, which undoubtedly include the ability to abstract and annotate texts, becomes especially important for all categories of students.

Modern technologies fundamentally change the process of their formation, making it much more streamlined, efficient and of high quality. The verbal action algorithmization technology, which is based on comparing the method of verbal-communicative activity to the principles of computer programming, has a positive impact on the organization of the learning process, the activities of all its participants, increases its effectiveness and allows you to quickly train any categories of students in the skills that are in demand in present. Using the principles of verbalization algorithms in relation to learning abstracting and annotation undoubtedly gives a positive result and becomes an effective mechanism for organizing the educational process, which is confirmed by the data of our study.

Prospects for Teaching English at Higher Education Institutions in a Digitalized Educational Process

Mikhail N. Kovalev

Abstract This article discusses the latest trends in the digitalization and computerization of education today, which contribute to the overall process of introducing modern technologies into education, as a process of a stable global trend, which entails an improvement in the content, forms and approaches to learning and in general throughout the education system. Particular attention is paid to the use of electronic testing schemes in the classroom while teaching foreign languages. The article also analyzes the process of teaching English in higher education institutions in the context of digitalization of modern society. Forms of this activity, such as online learning and classroom teaching, are considered. The comparative analysis of both forms of teaching is carried out, their advantages and disadvantages are revealed in the light of the rapid development of innovative technologies, computer systems and artificial intelligence. The reasons for the crisis in the existing classroom form of teaching English and the growing popularity of language learning in the online space are analyzed. The prospects for developing classroom and online language teaching are outlined. Recommendations are given on how to effectively combine both forms of teaching in the process of teaching professional English to university students in an ever-changing professional and business environment. Digitization of education in the area of teaching a foreign language implies providing students with opportunities to improve their knowledge of a foreign language through the use of a huge number of paid and free resources. The introduction of online courses and the support of courses with an online component are gaining high popularity around the world. The online component provides an opportunity to practice the skills formed during the implementation of the main part of the discipline, thereby taking out the old teaching method. A wide range of proposed innovations will help to solve the tasks set by the society in terms of training highly qualified personnel in the future.

1 Introduction

Nowadays smart technologies within which the newest technologies are created and integrated, allowing to receive new knowledge and skills by means of artificial intelligence, as well as special methods of processing of big volumes of information have received wide distribution. Digitalization as a new trend of the world social development replaced information and computerization and leads to higher economic efficiency and better quality of life [1]. The Smart Nations phenomenon is a new kind of humanist concept [2], which is gradually being applied not only in the economic sphere, but also in education. Today's trends in education are somewhat similar to those of the economy and one of the most significant among them is digitalization. Educational processes are becoming digital: lectures and seminars are held online, textbooks become electronic, conferences are held via video, and much more.

The scientific novelty of this study is noted by the fact that today many Russian universities are making the educational process with the participation of MOODLE—a modular object-oriented dynamic learning environment. This system has gained worldwide recognition. In this way, the Internet portal «Derzhavinsky online» was created on the basis of MOODLE at Tambov State University. G. R. Derzhavin, it focuses on the promotion of educational services in electronic format. Working with the portal allows you to introduce new educational technologies (business simulators, virtual laboratories, etc.) in the educational process. Peoples' Friendship University of Russia uses the TUIS telecommunication educational information system, created on the basis of MOODLE [3].

While working with the training portal, the teacher must master the competence in filling the program with copyrighted materials. In turn, students also form competencies related to the fulfillment of the tasks of the electronic course, the ability to navigate and interact in the structure of the course and the search for the necessary information to solve the educational problem.

One of the goals of such courses is to help students find information on their own. The need to work with great amount of information both on their first language, and foreign language for analyzing the situation, forecasting, and problem- solving requires proficiency in a foreign language [4]. The modern educational environment has huge information resources, which makes the learning process more accessible.

Remote and interactive interaction between teacher and student currently holds a strong position in the educational process. Modern universities are increasingly using electronic learning platforms in the educational process, on the basis of which teachers publish their courses in addition to working in the study room. This is reflected in the activities of a foreign language teacher, which is growing with help of the components of professional competence in the development of electronic courses, the introduction of distance and online learning.

In this regard, the issues of searching for optimal and effective teaching methods, ways of constructing and presenting information and materials, creating a natural learning environment while digitizing the educational space are becoming relevant today.

2 Background and Methodology

Language is so involved with the rest of our lives that it penetrates everything we do, and everything we do penetrates language [5]. English is the most popular language that students strive to learn, which is why the process of teaching this subject is given special attention. With the digitalization of the educational process, English in higher education is not only taught in a traditional system where students learn the rules and grammar while sitting in the classroom, but also new delivery systems are emerging, the most common being online, i.e. online classes. However, there are debates within society about which method is most effective and which has the right to exist in higher education institutions in the future.

At the current level of higher education, English plays a leading role in a significant number of subjects, and some are taught to students in English rather than their native language. Under these circumstances, higher education institutions are faced with the objective question of how to provide their students with a quality foreign language education program. It is with the aim of solving this problem that many teaching methods have been developed and are successfully functioning, providing knowledge to millions of students.

However, social development does not stand still, with the increasing level of technological development, modern methods of teaching are being created, which are a real breakthrough in this area. Language planning and other- than-language planning face similar burdens and benefit from related social and organizational circumstances [6]. What is the prospect of teaching English in higher education today? What awaits us in the future? Preparing an answer to this question requires a detailed study and research of the current situation, as well as forecasting possible scenarios for further development of the educational system.

3 Discussion and Results

Let's first look at the current state of the English language in the world.

According to studies, the number of graduate and postgraduate students who use English during their studies and also communicate in this language is more than 60% [7]. The introduction and spread of English in higher education has been so powerful and rapid that it has led to controversial debates in the national media and an attempt to legally limit its growth. However, it is an undeniable fact that in non-English-speaking countries there is a rapid increase in the number of students who want to

learn English or are already taking steps towards their goal. Universities and colleges encourage the desire of their students by increasing the number of such foreign languages within their campuses. Now English is not only a compulsory subject at school, but young people study it at least until they are employed, regardless of their chosen profession. In addition, some sciences, especially humanitarian ones, are not currently taught in the mother tongue—English is the language preferred by heads of educational institutions.

Also, according to studies, the rating and prestige of the university are inextricably linked with the frequency of English language use [8]. Any university prefers to have the status of an international institution, to be known and respected, and this is impossible if its student body cannot be called international. This quality is achieved, first of all, by the ability of students to speak English, which is generally considered international.

As a result of the above, it is possible to understand how important and relevant the process of competent and effective English language teaching at higher education institutions is. However, in addition to the process of internationalization, educational institutions have another trend—computerization. Its consequences are visible everywhere: there are computers and projectors in classrooms and most information is provided electronically. This option is beneficial to both parties: students perceive information better and faster, and the university can thus provide more knowledge and test its effectiveness. Having analyzed this information, we can conclude that online education in disciplines, especially English, is a more appropriate and effective approach, replacing classroom teaching. Next, we will examine and analyze whether this is true.

Online education is becoming more and more popular with students around the world. While many people find online education less effective, they would be surprised to learn that a recent study conducted by SRI International (on behalf of the U.S. Department of Education) concluded that, on average, students in online learning environments performed better than those who received full-time education [9]. So, what are the pros and cons of learning English online?

The biggest advantage of online education is increased flexibility. You can learn English anytime and anywhere. That does not mean less workload for an online student, but that they have more flexibility in when, how and where they learn. Learning English is more effective with frequent repetition, and that is what online learning offers. It is better to review English for a few dozen minutes a day than to do it for one or more lessons per week.

Another significant advantage of online learning is accessibility. All you need to be able to learn online is a computer with the Internet access. All your learning materials, lectures and assignments are sent to you by email or through a file transfer system. Even your correspondence with your teachers is wired, with email and video calls via Skype. Due to their extracurricular activities, a lot of students cannot attend absolutely all lectures and seminars. Online learning allows students to do it at a convenient time.

However, despite the perceived advantages, one should not forget the disadvantages of this form of education. Many companies and institutions are quickly abandoning online education. If two candidates are interviewed, who are absolutely the same in all respects, except that one studied at a regular university and the other studied on the Internet, in most cases, a student who studied on the Internet, will not be able to beat their "rival". Employers are particularly biased towards English, which is currently an integral part of any job. That is why they prefer to study this subject as an instructor-led subject, which is a guarantee of communication skills with other people in English.

The Internet is an emerging phenomenon; it is still in its infancy, and so it is not surprising that there are some shortcomings in online education. English has not developed on the Internet enough to provide such comprehensive knowledge as a university teacher.

As for traditional classroom options, such classes still predominate in modern higher education institutions and have a lot of supporters. It is training in direct contact with a native speaker and in live communication that can be most effective [10]. It is not only the voice of the teacher sounding from the computer that matters to any person, but also the visual contact, the opportunity to demonstrate something or find out immediately.

Yet traditional classroom learning is becoming less and less relevant as students are becoming less and less interested in sitting in stuffy classrooms and studying dry theory, solving the most classical English assignments: reading texts, doing grammar exercises, tests, etc.

It is common knowledge that even traditions require modernization. Therefore, modernization is also necessary for this traditional method of education. The main purpose of such changes should be some transformation of the format of presentation of material, in order to attract students in the same way as online learning does. This problem has been addressed by some universities and researchers together with their professors. As a result, several concepts have been created so far that are aimed at changing the structure of teaching in the classroom, which should allow this method to stand on a par with online learning and even compete with it.

One of the best known ways to do this is through the CLIL (Content and Language Integrated Learning) approach, which helps students not only learn English as such, but also learn it as a subject with its own features and complexities [11]. This method includes the potential to develop students' communication skills and their interaction with each other, teamwork skills in the process of learning a subject through a foreign language and a foreign language through the taught subject. In addition, the methodology aims to maintain and strengthen intercultural communication, which has significant social potential. The benefits of the approach are directly or indirectly associated with an extensive body of research from a variety of fields [12].

In comparison with the traditional way of foreign languages learning CLIL is considered to be a conceptually new experience because the content of a subject and a foreign language are learnt simultaneously [13]. With this approach, English is learned not only for academic purposes, but also for everyday communication, which is an important aspect, as in today's environment, international language is used in all

spheres. Its relevance is absolute. The need for the student to have not only theoretical knowledge, but also to be able to use the language fluently in the communication process is evident. Then the student will be in real professional demand.

It would be expedient here to make a comparison with demand of experts in hard sciences: it is not the one who solves certain problems on a known pattern by application of concrete knowledge and laws appreciated, but the one who can freely and quickly find solutions for non-standard and atypical problems. The same is true of English: student training should include more than just learning grammar rules and vocabulary, although this is basic knowledge of any language. It is crucial to adapt the student to informal conversations, professional dialogues and monologues, in short, to develop the skill of fluent communication in all situations. The main goal of any higher education institution in terms of foreign languages teaching is to release a competitive professional who is ready to live and work in market-driven economy terms, who desires and is able to communicate [14].

A significant problem in the implementation of all these aspects is overcoming the language barrier, when the student has all the necessary knowledge, but cannot freely apply it in the communication process. It is precisely the task of overcoming this barrier that comes to the fore with the CLIL approach.

Another innovative approach to learning English is EMI (English Medium Instruction) [15]. This system involves learning a language in a specific context that will be most relevant at a given time. This method is now widely used for academic purposes, as it involves learning exactly the necessary part of the subject content. In this way, students acquire valuable, relevant and professional knowledge that will be useful for them in their future professional activities. Departing from traditional methods of education involves learning the language of the professional sphere, in order to obtain quality and specialized professional education.

And yet we must not forget that any method has its shortcomings. If we talk in general about learning within the classroom, that is, the classical method, it is worth mentioning that the methods described above are not used in every university, and not all teachers know about their existence [16]. Therefore, the general trend of classroom education looks like an outdated form, which requires reform and change, or should go down in history as a relic of the past.

Due to the fact that the speed of spread of innovative teaching methods is not high, today there is a growing trend to reduce and replace the practice of classroom training with online training. In the long run, a total change in the form of English language education may take place before the new teaching methods reach higher education institutions. Classroom learning is therefore at risk of gradually disappearing, as the rapidly growing Internet can only present the same thing as conventional learning but a lot simpler and faster.

In the light of the trends described above, language learning at higher education institutions becomes more narrowly focused and aimed at obtaining knowledge in a specific field in demand. Higher education institutions offer students the study of English within their specialization, with the possibility of taking online courses both from their own and from the world's leading universities. Today's reality is fundamentally different from that of a few decades ago, when English was taught in

a unified program for completely different areas and profiles of professional training. By adding a professional orientation to the training process, there is an increase in students' interest in studying the subject and an improvement in the overall quality of education received in the university [17].

Despite this, classroom training can and should have a chance for further development. Nothing can compare with the benefits of live learning through direct contact between the teacher (especially native speakers) and the learners and students with each other. If innovative approaches and methods of teaching English are spread and consolidated in higher education classrooms at the same speed as online, if teachers are as flexible as they are in responding to the constantly changing conditions and demands of today's professional and business environment, then the classroom form of English teaching will not be inferior to online learning and will eventually reach a higher level.

The development of online education is also not standing still. While classroom training requires the development of new techniques through long-term research, online learning evolves in step with the development of innovative technologies, computer systems and artificial intelligence. All these areas form a single base on which online learning is built. Thanks to the development of modern technologies, research and development of methods of teaching English online is becoming more efficient and less resource-consuming. That is why, speaking about the future prospects of online learning, we can make positive predictions based on the recent significant development of IT-technologies, which contribute to the provision of new opportunities and forms for this type of learning.

4 Conclusions

Summing up the analysis of the prospects of teaching English at higher education institutions, it is worth noting that both classroom and online learning have positive prospects for each of these forms of education to stay, transform and evolve in higher education institutions. Classroom learning is currently undergoing a certain crisis related to outdated teaching tools. Despite this, new teaching methods are being actively created and introduced, which are designed not only to save the classroom form of education, but also to bring it to the highest level of efficiency and effectiveness.

However, today's students prefer online learning because of its convenience, reduced time consumption and high efficiency. The potential of this form of training has not yet been exhausted and has many promising areas for development. Therefore, online learning will occupy a leading position among the forms of education of students for a long time. But we should not forget that it is classical classroom training that virtually had no alternative for many years. In addition, digital solutions cannot replace the teacher in the formation of productive skills (speaking and writing) [18]. We should not expect this form to completely outlive itself in the near

future. On the contrary, much is being done to modernize this form of training, which in the future should give its results.

On the Prospects of Pedagogical Technology "Flipped Classroom" in Teaching History at University in Conditions of Digitalization of Educational Environment

Yuliya P. Nadehina, Andrei A. Kolchin, and Yuliya A. Myshko

Abstract This study is devoted to such an urgent issue as the development of a concept for improving the teaching system of the discipline "History (Russian History, General History)" at the State University of Management, using the "inverted class" pedagogical technology as an example. In the modern world, recently there has become a need for a significant expansion of the digitalization of education. Russian educational institutions, acting in accordance with Russian legislation, are forced to introduce digital technologies in the organization of training. In these circumstances, the necessary transformation of the model of classical education becomes the primary task of every teacher and teacher. It's very important to create a completely new educational environment using the latest digital technologies that meets the needs and requirements of students. Mostly, teachers and educators need to pay attention to the development of content for various platforms and also update tasks on each topic of the course. In the new conditions, teachers should pay special attention to conducting video conferences, video lectures, webinars, and other classes online. The concept of improving the system of teaching the discipline "History", which is proposed in the article, is based on practical experience identified in the analysis of the questionnaire of teachers and students, which was carried out in February of the current school year. The scientific novelty of the study lies in the fact that earlier at the State University of Management and, especially for the teaching of the discipline "History", the teaching technology, which is called the "inverted class", wasn't applied. The results obtained during the implementation of this research work are mostly recommendatory in nature and should be tested in the near future.

1 Introduction

In the modern world, more and more attention is paid to information and communication technologies. They penetrate into all areas of public life. Transformations are subject to public administration, economics; even the social environment is increasingly involved in digitalization.

Information technologies open up new spaces for the development of science and education. It is noteworthy that in the context of digitalization, education becomes personified, which, according to D. Moshel, a specialist in the implementation of DXC Technology, will allow each of us to lead the life he dreams about.

In this article we will talk about some features of teaching history by specialists of the Department of History and Political Science of the Institute of Public Administration and Law of the State University of Management (hereinafter –SUM).

In the Russian Federation in recent years, the state has been actively promoting digitalization of education. Thus, according to the Decree of the President of the Russian Federation dated May 7, 2018 "On National Goals and Strategic Development Objectives of the Russian Federation for the Period until 2024", the Government of the Russian Federation in the development of the national project in the field of education should proceed from the fact that in 2024 it is necessary to ensure: the introduction of new methods of training and education, educational technologies at the levels of basic general and secondary general education, which will allow students to master basic skills and abilities, increase their motivation for learning and involvement in the educational process.

A similar attitude is also contained in the Strategy for the Development of the Information Society in the Russian Federation for 2017–2030. The main value of the modern world is information. For the full-fledged formation of a person in modern society, it's necessary to create a generally accessible system of interconnected knowledge, skills that form the competencies necessary for our contemporaries. All this requires a new approach in the implementation of educational programs. The document also emphasizes the need to develop educational technologies, including distance and e-learning.

Also, the meeting of the Presidium of the Presidential Council on Strategic Development and National Projects on December 24, 2018 resulted in the approved passport of the national project "Education". One of the federal projects "Digital Education Environment" includes a step-by-step, up to 2024, creation of a modern and secure digital educational environment that provides high quality and accessibility of education of all types and levels.

Thus, educational institutions were forced to introduce digital technology in the organization of training. As experience shows, in the foreseeable future, the competitiveness of the educational institution will be largely determined by the completeness of the introduction of digital technologies. After all, digital technologies have long and firmly entered our daily lives: people in megalopolises communicate using instant messengers, make daily purchases via the Internet and order taxis with using special applications on smartphones.

Online education is also being introduced into the Russian education system, and our university is one of them. The scientific novelty of this research work lies in the fact that earlier in the State University of Management and, specifically, for teaching the discipline "History" at the Department of History and Political Science of the Institute of Public Administration and Law, the teaching technology called "inverted class" wasn't applied. The results obtained in the process of implementing our study should be tested at GUU in the near future.

In general, a large number of different educational platforms have appeared recently; many online courses have been created at universities in the country. So, for example, in 2015, the national platform "Open Learning" was formed. The main principle of this portal is the availability of education, in view of this, courses on this platform are provided free of charge by the leading universities of the country.

In the modern world, there are a variety of educational resources and many of them are actively used today in Russian universities.

- Sites for holding group video conferences, webinars, etc. (Zoom, Webinar, Myownconference, etc.);
- Services for group work on projects (Miro, Bacecamp, etc.);
- Services for online testing, mini-games (Mind, Mentimeter, etc.), etc.

Of course, the introduction of new digital technologies can't be an alternative to classical learning. The most effective option is blended learning, which includes the using of digital technology as a complement to classroom education. This scheme has long been actively used in foreign countries and it's now being effectively implemented in Russia.

2 Background and Methodology

In order to implement the "flipped classroom" method in the process of teaching history at the State University of Management it was necessary to get acquainted with its complexities and contradictions. In this regard, the authors turned to an overview of the latest pedagogical research on this topic.

A. G. Gerasimova, while reviewing electronic educational resources, notes that the application of new digital technologies is an integral part of modern education system [1].

The main topic of the article by M. Gurkova is analyzing the need to introduce the "inverted class" technology. According to the author, in the near future, this

methodology will become the basis of education. She thinks that the main reason for this is the different speed of assimilation of material by students.

During the classical academic classes, students have no opportunity to pause, return and listen to the material again, in contrast to the possibilities offered by the "inverted class" methodology.

More and more educational institutions are abandoning standard methods of teaching various disciplines, including humanities, and are trying to introduce digital technologies into the learning process. This leads, first and foremost, to the abandoning of penmanship and reading of literature in printed form. Many studies have found that, from the perspective of human development, a complete transition to digital education can lead to the inhibition of some particularly important psychophysiological functions and mental processes, such as motor skills, coordination, imagination, memory, speech and thinking [2].

According to O. I. Babich, innovations in domestic education, including its digitalization, carried out in recent years and they also create new conditions for university teachers. According to the author, teachers are increasingly experiencing professional stress, the overcoming of which leads to emotional burnout [3].

R. A. Abdurakhmanov also speaks about this in his research, pointing out that 82% of the teachers surveyed pay attention to factors that increase their emotional burnout. First of all, we are talking about increasing the amount of time that teachers spend on the development and processing of methodological documentation [4].

According to N. L. Antonova, blended learning, including the use of the flipped learning model, is becoming one of the significant breakthroughs in technology and teaching methods [5].

N. V. Tikhonova expresses the opinion that the key change in the education system in the conditions of "flipped learning" will be that the classroom and out-of-class work with students will change places [6].

A. S. Robotova raises similar problems when considering personal perception of distance learning by a teacher of humanities and arising problems in its implementation: "creation of an electronic human text, preservation of the dialogue inherent in it; overcoming alienation from invisible students; creation of own image; organization of online communication" [7].

A. M. Korenchenko and E. A. Kalinina, arguing in an article about what an inverted class is essentially: a method or a learning technology, note the advantages of the method. Students come to class prepared and the teacher doesn't need to spend time on the theory. At the same time, the main advantage is that the teacher has the time "to sort out all the questions that students had during the preparation of the topic and try their hand at solving practical problems, performing laboratory and control works".

It's also worth noting a number of applied researches, in which the question is posed: "How to implement inverted education at a university?" (Look, for example, [8, 9] and others.) In these studies, numerous difficulties are noted in the introduction and application of new technology in educational institutions.

David Moschella believes that the main changes in education today are the functioning of mass open distance courses, and the future belongs to "flipped classroom" [10].

The "flipped classroom" method emerged from the initiative of American high school teachers J. Bergmann and A. Sams. Interested in the good results of the subject, teachers decided to fill in the gaps in pupils' absences with video lessons. According to the materials of the video lessons, the students independently mastered the missed topics. It is noteworthy that this method became very popular among students and initiated the formation of a new pedagogical technology.

It is important to note here that the "flipped learning" model is a system for constructing a non-linear educational environment in which modern achievements in the area of information technologies are applied [5].

3 Discussion and Results

In fact, the model of the educational process called "flipped classroom" at the University may look like this: the teacher provides students with the material for self-study, and in practical classes in the classroom the material is fixed. According to practicing teachers, at the second stage it is necessary to use both active and interactive forms of learning [6].

The use of vodcasts, podcasts and pre-vodcasting is typical of "flipped learning". It is basically an audio or video lecture that the instructor sends out by subscription via the Internet. Learners can download material to landline or mobile devices or listen to lectures online.

Pre-vodcasting is distinguished by the fact that the instructor dispatches the material in advance so that students have an idea of the topic before the class in which the topic is to be discussed.

In the conditions of "flipped learning", work in the audience is devoted to the analysis of the most complex aspects presented in the lecture. The main part of the classroom is spent on practical and research tasks. A prerequisite is the consolidation of knowledge, skills in home and subsequent classroom assignments.

In accordance with modern standards of higher education, the curricula of bachelor's programs in the areas implemented in SUM should include disciplines (modules) that provide the formation of universal competencies. This includes the History discipline (Russian history, universal history). Teaching of this discipline in the majority of higher education institutions is carried out according to the classical academic scheme: reading of lectures + carrying out of practical classes where the most difficult topics are considered. As practice shows, this scheme is much outdated and should be changed.

The above mentioned justifies the application of the "flipped classroom" method, which can be used by the lecturers of the History and Political Science Department of the State University of Management within the framework of reducing the number of lecture hours in favor of practical work with students.

For effective implementation of the "flipped classroom" technology among first-year students and teachers of the History and Political Science Department of SUM, a survey was conducted on the readiness to study and teach academic disciplines in the conditions of this method, as well as the presence of possible barriers that prevent its implementation in the educational process of SUM.

The State University of Management is one of the leading universities in the country with centuries of experience in training managers. Today the University trains students in the following fields: "Management", "Economics", "State and Municipal Management", "Advertising and Public Relations", "Political Science" and others.

The University consists of 6 training institutes, which bring together over 40 academic departments and research divisions. The Department of History and Political Science of the Institute of Public Administration and Law includes professors and associate professors with extensive experience in teaching history. The lecturers of the department strive to use new pedagogical technologies, in particular, they conduct classes in active and interactive forms.

In accordance with the Federal State Educational Standards of Bachelor's Degree programs, the discipline "History" is a mandatory (basic) part and is taught to first-year students in almost all areas in which SUM provides training. Annually about 1000 students study at the first year of SUM.

As part of our work 105 first-year full-time students were interviewed (78 females, 27 males), as well as the teachers of the History and Political Science Department of the Institute of Public Administration and Law of the State University of Management working in the 2019/2020 academic year. Respondents were offered authorial questionnaires.

The student questionnaire contained five questions. The first three were multiple choice questions, the remaining two were open-ended questions.

As a first question, students had to answer whether they had enough information from the lectures to study the history course and prepare for the exam in the discipline. Students were also asked to clarify whether they would like to receive information in the subject they were studying online, in addition to the main lectures, and whether they were willing to interact with the teacher online within the history course.

In the open questions students had to answer to what extent they were ready to use computer technologies to organize their independent work, and also to explain whether the university was equipped enough to use computer technologies in the educational process.

The results of our research revealed a low level of awareness among students and teachers of SUM about the "flipped learning" model.

The information received at the lectures for studying the history course and preparing for the exam turned out to be quite enough for the majority of students—82% of those surveyed. It was insufficient for 18%, including respondents who said that the history course as a whole had few class hours. However, these data were obtained from students studying under the "traditional scheme": lecture—practical work (seminar)—independent work of students. Whereas, for the upcoming

academic year, the Department of History and Political Science of the State University of Management has plans to reduce the number of lecture hours in favor of practical work with students.

As a matter of principle, despite the high willingness of the student community to join the model of "flipped learning" (51.4%), students note a wide range of obstacles related to the conditions of its implementation and difficulties in independent mastering of the material (lack of skills to distinguish between the main and secondary educational material; insufficient organizational culture of independent work, etc.). 47.6% of the surveyed students exclude the possibility to work in such a format. Only 1% of the respondents stated that the information from the teacher was provided online, so it was possible to assess the benefits of online learning. The analysis shows that the majority of students are potentially ready for the introduction of the "flipped classroom" method.

This conclusion is confirmed by the answers received to the third question of the questionnaire. The majority of the surveyed students (64.8%) unambiguously declared their readiness to interact with the teacher online within the framework of the history course. Whereas 35.2% of respondent students are not ready for such an educational format.

As part of their independent work, 69.5% of the surveyed students indicated their readiness to use information and computer technologies. 30.5% were ready to use computer technologies not completely and permanently (if necessary, or if it is necessary to work in word processors and other well-known programs). The answers received indirectly confirm the readiness of the majority of students to engage in work by the method of "flipped classroom".

The last question was to demonstrate the students' assessment of SUM technical equipment. According to the majority (53.3%), the university has not created all the necessary conditions for the use of information and computer technologies in the educational process (unstable WI-FI; many classrooms are not equipped with the necessary technical means of education, etc.). On the contrary, 46.7% of the responding students indicated in their answers that conditions for the use of information and computer technologies in the university have been created. Such an obvious "dispersion" of opinions can be explained by rather subjective ideas of students about the quality level of information and computer technologies themselves, which should be used in higher education institutions in modern conditions connected with general digitalization.

The lecturers of the Department of History and Political Science of SUM were offered to answer six questions, including three multiple choice questions (about the use of information and computer technologies; indication of concrete means and frequency of their application). The questionnaire also contained three open questions on possible problems with the use of information and computer technologies and creation of conditions for digitalization of the educational process.

The results of the survey showed that no teacher had yet fully worked according to the "flipped classroom" method. 85.7% of the teachers surveyed turn to information and computer technologies when preparing for classes, of which 50% also use them

for self-education and 33% use them in the class. And 14.3% of respondent teachers use them only for self-education.

71.4% of the teachers surveyed use information and computer technologies every day, while 28.6% use them 1–2 times a month.

The majority (85.7%) of respondents actively use a text processor and the Internet; 42.9% of teachers use specialized programs. Only 14.3% of the teachers surveyed access multimedia discs and spreadsheets. All respondents unequivocally agree that the use of information and computer technologies significantly facilitates the preparation for the history course.

Most of the teachers-respondents reported that the university had not created the necessary conditions for the use of information and computer technologies, which can be extended to the "flipped classroom" method. Many people have problems with the use of information and computer technologies in the university (rooms are not equipped enough; it is difficult to work in them because of technical difficulties: network outages, viruses, etc.). It is noteworthy that even "confident users" are not sufficiently aware of information and computer technologies: they do not always have the necessary computer training experience to fully work with students.

The main reason for the situation revealed in the course of the survey among the teachers of the Department of History and Political Science of SUM is the lack of information on innovative technologies of education, as well as the lack of necessary skills in such practices and competencies. This is primarily due to the fact that most of the teachers surveyed received their degrees 20–25 years ago, i.e. at a time when "new teaching models and methods" did not appear. It is also obvious that almost all teachers have classical university education obtained in universities, where there may have been no pedagogical disciplines aimed at mastering specialized methods of education and upbringing.

Many teachers work at the Department of History and Political Science of SUM on a part-time basis (they teach at other educational institutions, are engaged in administrative activities, etc.). And this raises the question of the lack of time as another barrier to the implementation of the "flipped classroom" model.

In general, the full functioning of the pedagogical model of the "flipped classroom" requires, first of all, the methodological and psychological readiness of teachers of the Department of History and Political Science of SUM and a thorough technical training related to the selection of necessary teaching material, recording HD-videos. But at this stage it is rather difficult to implement it in SUM. However, since the problem of revising the accounting of teaching time allocated to different types of classes has already been raised, it may be possible to start the implementation of digitalization of social and humanities education in the next academic year, and in the case of the Department of History and Political Science it may be related to the method of "flipped classroom".

4 Conclusions

As a result of the conducted research, it became obvious that the "flipped classroom" model, despite the growing interest of subjects of the educational process of the higher school system and readiness to join it, cannot yet be fully implemented in SUM. The following circumstances indicate this.

Firstly, the students surveyed have the desire to work independently, but not always have the necessary skills and ability to plan their time.

Secondly, the level of awareness of the "flipped classroom" model among both teachers and students is low, they prefer to use traditional methods in the educational process.

Thirdly, one of the obstacles in the implementation of the described pedagogical model is the lack of sufficient information and computer equipment in the university, and this creates problems in the possibility of technical support.

Fourthly, the faculty does not have enough free time to prepare appropriate teaching materials for digitalization of the educational process.

At the same time, there are prerequisites for the use of the "flipped classroom" model in SUM, namely, the appeal of teachers of the History and Political Science Department in their practical activities to information systems and programs aimed at meeting the needs of modern students. In order to strengthen this trend, it is necessary to centrally conduct professional development courses for employees related to the implementation of educational programs, using both experienced and young specialists, in order to form competencies in the field of information and computer technologies to optimize the educational process in the emerging digital economy.

Creation and Use of Management Resources Based on Corporate Digital Platform

Aleksandr V. Raichenko, Olga N. Gromova, and Galina M. Sundukova

Abstract The purpose of the work is to justify the definition, positioning and use of management resources on the basis of a corporate digital platform that provides their formation, adaptation and application in processes, systems and mechanisms of targeted impact of a modern organization. The research presented in the paper is based on formulation, adaptation and use of the concept of continuous development of management potential, adapting and applying process, system and complex approaches on the basis of mobilization of possibilities of the corporate digital platform. Selection for statement and a combination of application of classical and innovative approaches to carrying out the research provide the constructive organization and effective creation of accumulation, processing and presentation of the accumulated information, development, approbation and adaptation of concepts, substantiation and formulation of the main conclusions and concrete recommendations presented by the present publication. Highlighted provisions, construction logic and key research results presented in this publication clearly illustrate the analysis carried out, the developments received and the proposals formulated based on their results by examples of the formation, mobilization and use of social resources of management of organizations based on the opportunities and prospects of corporate digital platform development. The analysis of the formation and use of management resources is carried out in the format of case studies and mechanisms for setting and solving a number of functional and complex tasks, adaptation and application of the produced impacts. The content of conclusions, findings and recommendations presented by the publication of the study determines priorities, procedures and opportunities for the formation and use of management resources in digital formats of development of

1 Introduction

All resources of management, as a process of development, adoption and implementation of targeted impact of the subject on the object, are presented, adapted and used in the form of information. With the development and implementation of modern digital technologies, it is becoming more deterministic and adequately reflects the subjects, means and products of managerial work, providing a confident solution to an increasingly wide range of tasks, from planning and coordination of actions, to improving the effectiveness of the results of setting, maintaining and achieving organizational goals [1]. The digitization of certainly formalizable objects has been carried out constructively since the 70s of the 20th century, including the format of automated process control systems [2]. The digitalization of probabilistically functioning object management is developed, maintained and developed on the basis of digital corporate platforms, which provide constructiveness, adequacy and efficiency of accumulation, processing and application of the whole variety of management resources [3]. These assessments are due to the relevance of the development of the topic presented in this publication and studies that combine the formulation and application of fundamental approaches, processing and adaptation of operational data of organizations, development and formulation of conclusions and recommendations for further development of the formation and use of management resources based on digital corporate platforms.

2 Background and Methodology

Definition of a research topic requires the formation, formulation and application of methodology based on a process approach to the organization of identification, analysis and construction of its main structures and results in contrast to the currently used system representation, which statically reflects the analyzed with a certain lag

lag.. It is caused by definition of management as process of statement and achievement of the purpose, interactive nature of carried out interactions [4], dynamism and radicality of conducted changes, whose adequacy, constructiveness and efficiency of the analysis and estimation in many respects define maintenance of realization of tasks in view.

Presentation of the results of the process approach application in management studies and constructive development of key provisions, developments and adaptations, formulation of its results determine the expected demand for the use of the system approach, in conditions of the need to provide support for continuous development of procedures and structures of modern organization functioning [5]. Adaptation of application of the demanded methodology to specificity of studies of formation and use of management resources on the basis of digital corporate platforms allows to analyze adequately, reasonably present and adapt its basic positions, results and conclusions in the organization and carrying out, both innovative scientific search, and applied professional activity [6].

3 Discussion and Results

Since the end of the twentieth century, the structural resources of modern digital technologies have been developed and applied primarily in the procedures of analysis, assessment and prediction of the development of the situation, justification and development of options for targeted impact, simulation of processes and results of their implementation [7]. Today, these opportunities are increasingly in demand, adapted and used in virtually all areas of interactive socio-economic interactions, providing the necessary level of manageability [8]. The creation of digital corporate platforms opens up fundamentally new and potentially unlimited opportunities for accumulation, systematization and processing of information necessary to ensure effective management, in the promising format of "Big Data". From these positions, the formulation and application of a process approach based on a digital platform becomes the basis for the development and application of a whole range of techniques for ensuring the innovative organization of research.

One of the constructive bases for mobilization, adaptation and use of the opportunities provided by them was the establishment and application, for example: method of interactive indication, independently identifying and evaluating the reactions of the corporation's personnel to the development and implementation of socially significant changes in the format of the process build.

Guaranteed by its application, ensuring the independence of choice, formulation and use of the composition and content of reaction evaluation indicators allows to overcome the affiliations of setting and solving such problems with stakeholders, as well as provoking subjective evaluations and destructive solutions imposed by them. It allows to constructively overcome frequently engaged social researches which form the distorted image of perception, an estimation and reaction of the personnel of the

organization to planned transformations, readiness of its constructive participation in forthcoming changes.

Basic innovations of the methodology are the development of programs to identify resonance reactions of personnel to the official and latent dissemination of information on planned organizational changes affecting the interests of employees of corporations. The scientific novelty of the justification and development of such programs has become models that classify their algorithms by: goals, objectives, problems, solutions and consequences, organizationally identified by the intermediate results of the management process. The necessary databases for the formulation and application of this methodology are: public official documents, texts of speeches, professional publications, comments on forums, the results of registration of permanent feedback and other, originally digitized materials reflecting the specific positions of their authors working in the corporation. The application of the technology of identification and analysis of the "digital footprint" in a constructive format of processing of "Big Data", allows to reliably identify and adequately systematize the key formulations of personnel's response to the transformations under consideration or planned by the corporation's management, to assess their constructiveness, repeatability, responsibility, to identify sustainable trends, to develop tactics of targeted impacts.

Thus, on the basis of the formation and use of management resources mobilized by them, at the school of the management personnel reserve of Rocket and Space Corporation "Energia", scientists from the State University of Management [4] implemented a methodology to assess the development of competencies and incentives based on the results of professional development programs. The development of scientific research innovation continues with the testing of the development of methods for evaluating the input level of competence of trainees, a permanent mechanism for personalized support of the "digital footprint" in the format of "Big Data", firstly substantiated and applied by the authors in RSC Energia. The results of these developments are tested in the experimental mode of duplication of the educational process organization and assessment of training results at the State University of Management, which will allow replicating the adapted methods to the interested users [9].

Interactive methods are tested and applied in an experimental mode by a number of corporations that are consistently developing management resources based on the digital platform [10]. The interactive format for determining personal positions of employees, becoming a key tool for implementing promising developments, provides for the formulation of indicators evaluated by research, solely on the basis of the initially identified reactions of personnel. Strict limitation of their edition, in the format of selection and laconic design of the content, the most frequently expressed reactions, allows to form a reliable pool of the most widespread opinions, formalized and used as a scale of indicators, in the process of subsequent transformation and monitoring of personnel positions. Cyclical updating of the language, periodic ranking, evaluation of changes in the prevalence level, setting the proportion of the positions shared in such surveys provide a balanced view. Adaptable and applied on its basis, purposeful replication of actual combinations of these and other necessary

for management of inquiries, provide operatively reliable reflection of change of view of the personnel on planned transformations.

Adaptation of the method of interactive indication is carried out to such job groups of participants of the object of research, as: categories of managers, professionals, actors, requiring the appropriate processing of the method's implementation. Received data are differentiated by the levels of structuring, subjects of personnel specialization, tasks to be solved, functions to be performed and other job characteristics of the corporate management apparatus. This is necessary due to significant differences in the forms, content and manifestations of reactions of representatives of specific categories, levels and specializations, which make it advisable to adapt the formulation and implementation of applied research programs.

For example, research conducted by the authors at the corporation "Slava" showed that the officially declared positions of managers are usually predictably "in line" with the adopted corporate strategy. However, the reactions of actors, no less often, are based on a subjective assessment of the risks and opportunities that they personally expect as a result of the changes. Application of the method of interactive indication, taking into account such and similar specificity of obtaining and systematizing the results of the whole range of social research, allows to overcome the emerging distortions, providing significantly more adequate information to decision makers [11].

Research carried out by the authors in groups of managers studying for MBA programs has shown that the procedures of searching, accumulation and processing of reactions of actors, as a rule, does not often publicly demonstrate their content, not only in digital, but even in usually presented resources, require substantial specialization and adaptation. Most of the manifestations of such reactions are fundamentally different from the traditional latent format and veil the content of their declaration, dissemination and reflection. These features necessitate the development and application of adapted technologies for identification, systematization and constructive use of latent position determination. The use of interactive methods of research and assessment of trends in staff attitudes constructively solves such problems, ensuring adequate obtaining of hidden data, one way or another.

In addressing these and similar challenges, mobilizing the potential of digital applications has made it possible to use unofficial network sources to collect and process information, reflecting significantly more candid personnel positions anonymously. Naturally, to process such data it is necessary to develop and apply specialized tools based on the appropriate adaptation of the capabilities of digital corporate platforms to interact with public network formats in the modes of active positioning and targeted work in them. Practically unlimited possibilities of expansion and specialization of corporate digital platform tools allow organizing and carrying out such work permanently, on the allocated spectrum of actual directions, demanded positions, accentuated inquiries, providing wide and informative support to substantiation and development of constructive management decisions [12]. At the same time, it is obvious that legal support of setting up and application of such developments should be based on the increasingly developing legislative activity in this

area, development of adapted subordinate sectoral, corporate, intra-organizational acts ensuring the eligibility to use such specific management resources [13].

The installation and use of both the above and other tools, examples of which are given in this publication, should be ensured by the fundamental construction, permanent modernization and future development of the digital corporate platform application of the process approach. In one way or another, it is steadily demanded by the need to develop and implement an ever-expanding range of solutions for a wide variety of management tasks of an increasing number of modern organizations [14]. The real demand for developments of this spectrum often goes beyond the traditional concepts, actualizing the innovative tasks that seemed fantastic: from the normalization of conflict situations to the management of "talents", which already have precedents for constructive solutions [15].

The prototype of such platform became the automated information systems of the enterprises and the organizations, which were actively developed, formed and used since the 70s years of 20th century. Their technical support and software do not go in any comparison with the modern level of setting and application of digital technologies in corporate management. At the same time, databases, methods of indication, tasks that were solved using these resources, in some ways, correspond to today's constructions. Thus, modern corporations to a large extent maintain the structure of request and input of primary personal data in finding job seekers, selection of candidates, the competitive filling of vacancies, very limitedly using a wide range of applications, such as "digital footprint" technology, which significantly expands the composition and diversity, and at the same time increases the reliability of the information received and used. As the studies of the authors conducted in the corporation "Unifol" have shown, its application is constructively combined with a whole range of such usual procedures as: competitive selection, monitoring of the trial period, organization of "soft" rating voting, etc.

The constantly expanding possibilities of the digitalization of the economy determine the necessity and prospects of formation of the market of universal software products that provide permanent increase in the efficiency of formation and use of management resources based on the digital corporate platform. It is natural that it will initially demand, lean on, use tendencies of maintenance of resources of universality of construction, functioning and development of digital corporate platforms which inevitably comes into conflict with traditional closeness of modern within organizational solutions of management digitalization [16]. In this regard, one of the key priorities of digital transformation for modern corporations is the setting and application of "agile" (flexible) approaches to software development, which is now increasingly used by business. The development of promising solutions to this problem goes far beyond the scope of research presented in this publication, but the emphasis on it necessarily becomes one of the logical and relevant research findings.

Universality of the basis, specialization of statement and adaptation of application of constantly expanding toolkit of means and methods of formation and use of management resources on the basis of a digital corporate platform allow to solve the widest spectrum of rather various management tasks. So, the whole complex of sections of databases and software packages of the majority of corporations steadily

establishes norms and regulates their observance from the point of view of optimization of internal environment and organizational behavior of the personnel. This makes it possible not only to strategically build and promptly normalize procedures within corporate interactions, but also to provide constructive information and effective components of solutions to practically most of the tasks of effective functioning of the corporation.

4 Conclusions

The analysis of the materials and results presented by this publication of studies allows us to draw the following conclusions based on the above statements:

- digital corporate platform becomes not only an effective trend, but also a constructive basis for the development, implementation and maintenance of innovative approaches, formats, tools to improve the management of the modern organization;
- the basic capabilities of using the digital corporate platform ensure the development and application of the most promising interactive methods of management support for modern corporations, based on innovative scientific developments;
- the diversity of tasks, conditions and resources of management determines the expediency of digital transformation by setting and applying "agile" (flexible) approaches to the development and use of management software based on digital corporate platforms, providing process support for modeling;
- methods developed and digitally applied to improve the effectiveness of targeted impact represent a fundamentally new level of their setting and positioning, allowing for the permanent mobilization, modernization and replication of management resources in process format;
- the digital corporate platform provides unlimited opportunities for advanced development, design, experimental testing and applied adaptation of breakthrough solutions for the digitalization of the economy, ahead of the general level of development, innovative management resources.

The provisions presented in this publication and the conclusions reached by the authors of the studies provide a number of the following recommendations for the formation and use of management resources based on the digital corporate platform:

1. A digital corporate platform should provide a constructive framework for the development, production and use of an ever-expanding and specialized range of management resources for each organization in the process simulation format.
2. It is advisable to ensure constructive interaction of corporations with government agencies and infrastructure organizations through the implementation of a process approach to the construction of their architectonics and communication.

3. Progressive development of formation and use of management resources on the basis of digital corporate platforms should be provided by production and distribution of universal software products of the modern level of development through creation of a specialized market segment.
4. Social, sectoral, cooperative and other features of functioning and ensuring information security of corporations require the development, adaptation and application of a wide range of applied methods and tools for the use of management resources based on the digital platform.
5. Establishment, adaptation and use of management resources should be accompanied by permanently updated legal support, which should be provided centrally with the participation of the executive authorities.

The authors express their sincere gratitude to the organizers and participants of the international conferences "Actual problems of management", "EdCrunch", "Gaidar Forum", "Proceedings of the International Conference on Man-Power-Law-Governance: Interdisciplinary Approaches", **"**Stepping into the Future: Artificial Intelligence and Digital economy" and others who kindly provided panels for discussion and approbation of the authors' developments and forum materials used in the processes of adaptation of the provisions and development of strategies for further research development.

Assessment of Undergraduate Students' Readiness for Intercultural Business Communication within the Digital Economy Ecosystem

Tatyana V. Salynskaya, Arina A. Yasnitskaya, and Olga Morasch

Abstract The article is devoted to the issues of preparing future specialists for intercultural professional interaction in the context of the development of the global digital economy. As part of rapidly evolving standards in this area, issues are urgently needed that require detailed consideration. Namely: What is the role of education in the digital age? What modern teaching methods have already been introduced, and what else can be introduced into the educational process? One of the significant competencies for the implementation of professional and sociocultural activities remains the competence of communicative communication. In order to solve communication problems in an interpersonal and intercultural format, the specialist's ability to write written communication in a foreign language is distinguished. Proficiency in a foreign language as an important tool for professionally oriented training, knowledge of the format of document texts and practical skills acquired during the training process make it possible to more effectively carry out professional activities in modern economic conditions. The relevance of the study is determined by the many difficulties that specialists face in the course of working with various types of electronic documentation. The study used empirical methods such as observation, experiment, analysis, study and generalization. The article presents the results of a study of the level of preparation of a future specialist for written communication in a foreign language in the professional sphere. An attempt was made to identify the degree of preparedness of students for intercultural foreign-language written business communication in electronic format, to consider the specifics of linguistic and related difficulties. The research prospects lie in the further implementation of modern educational technologies, focused on the widespread use of active

1 Introduction

Under the current conditions of development of the new economy and Russian society, all spheres of social relations are rethought and modernized. The focus of transformations is on the professional activity, which is considered to be the main vector and priority of the state policy, as well as on the subjects of professional activity, to which higher requirements are imposed, which is reflected in a number of normative documents [1, 2].

In this regard, when digital technologies are defining new approaches to competence and competencies, considerable attention is paid to the process of developing human capital [3]. And this is not by chance, because the principle of "smart" organization and management is one of the leading in the development of digital economy, where human capital, knowledge, skills, artificial intelligence are the core values of the digital economy [4]. The main objectives of the "Digital Economy of the Russian Federation" program included areas related, inter alia, to the education system, whose task is to provide modern economies with competent specialists, and which is viewed as part of the digital economy ecosystem [5]. Digitalization in the area of education is a completely new construction of the educational space [6].

Taking into account the needs of society and business, special attention should be paid to the training of specialists who are in demand for the implementation of the tasks. In this regard, it is necessary to take a new approach not only to the content of educational programs, the choice of didactic means and methods used in the educational process [7], but also to the level of qualification of teaching staff and implemented pedagogical technologies [8]. In addition, both the form and content of work are changing. In the conditions of digital economy, Internet technologies are being actively introduced into all spheres of human activity [9] new requirements and professional competences are emerging, for example, lifelong learning and digital literacy [10]. In the conditions of constantly changing socio-cultural and economic conditions, the training of future specialists involves not only ensuring the professional development of the individual, focusing on self-development, increasing the level of readiness for productive activities, but also the ability to demonstrate effective socialization with a focus on socio-professional significant priorities and successful use of competitive advantages within the boundaries of the digital space.

As one of the significant tasks of modern vocational education, along with the required competences for professional, as well as socio-cultural activities in modern

digital infrastructures, possession of communication skills in the above conditions, both in native language and in a foreign language, should be considered equally. The introduction of digital educational programs is introducing changes in learning technologies [11].

We believe that the ability to successfully participate in written communication, both in the native language, which should be natural for the specialist, and in a foreign language in identical situations, is an important component of social and professional adaptation and career development [12]. The relevance of such a position lies in the fact that intercultural social and business communication skills and the ability to work with foreign-language documentation can help to identify and realize internal potential and determine one's place in the profession in the era of digitalization.

Researchers in their works offer evidence and explanations of why business communication is a relevant component in the education of students in a non-linguistic university. They emphasize that the formation and development of foreign-language written business communication skills are necessary for future qualified professionals to carry out professional activities in the framework of international business cooperation. This is linked to innovation processes, information and communications technology and the many business contacts that are rapidly growing in the digital economy. Particular attention needs to be paid to reducing communication difficulties, which have a negative impact on written communication across business and professional cultures [13, 14]. Such barriers include cultural diversity, similarities with native culture and stereotypical situations [15] . In order to address these problems, given the new digital realities, it is advisable to include in the training process a set of project tasks to develop and strengthen the skills of business correspondence in a foreign language. In addition, it is necessary to reasonably combine well-known generally accepted approaches and innovative technologies in the educational process. The use of modern distance learning and project technologies in educational activities will allow to keep the persistent attention and long-term interest of students at a sufficiently high level, as well as participate in joint student projects in cooperation with foreign universities.

In this regard, in the organization of the educational process for the formation and development of communication skills and skills necessary to work with corporate documentation and business correspondence, it is necessary to provide distance learning courses and projects aimed at preparing for this foreign language activity. It is also important to take into account a number of conditions, such as the linguistic level of students, experience of intercultural and professional communication, as well as the nature of future interactions, possible motives and patterns of behavior, readiness for transformation of the value system. The relevance of such training courses is largely due to the fact that the professional duties of specialists may vary widely, which may include extensive work with the company's internal documents (e.g., various subject-specific working reports, memos, letters, contracts, etc.).

2 Methodology

To study the awareness and readiness of students for cross-cultural professional written communication in electronic format, 194 written works of undergraduate students were randomly selected (business writing within the framework of the studied topics): 94 works of first year students and 100 works of second year students studying at the State University of Management (Moscow, Russia) at bachelor's program in two areas of training: Economics and Management. The implementation of this program presupposes the training of specialists capable of participating in foreign-language written communication within the boundaries of their professional activity at the end of the program, which means that graduates are ready to carry out business correspondence in a foreign language in an intercultural format.

The initial data of the research are the level of foreign (English) language proficiency established as a result of preliminary testing by the undergraduate students of the State University of Management and the list of difficulties they face in performing written assignments in the course of studying the foreign language. This data is necessary to analyze and assess students' readiness to participate in intercultural written communication in a foreign language (business writing).

The list of the selected difficulties includes not only linguistic difficulties, but also more related to the organization, logic and structure of information presentation, understanding of the problem situations proposed in the tasks, their subsequent analysis and search for possible solutions (Table 1). These difficulties arise in the performance of written tasks in the sections of Writing, which are included in authentic printed and electronic foreign language teaching materials developed by such publishing houses as Macmillan Education, Oxford University Press, and Pearson Education.

Initial data indicate a different degree of readiness of students to learn a foreign language at university within the requirements of the bachelor's degree program, which is taken into account when determining their readiness for foreign language communication in the format of electronic business communication, as well as classification and systematization of difficulties in writing business letters.

Table 1 List of identified difficulties

Difficulties identified	% (amidst the difficulties)
Organization and presentation of information	5
Logic of presentation of information	5
Information presentation structure	2
Understanding the problem situations proposed in the tasks	15
Analysis and search for possible solutions	73

Table 2 The results of testing the level of preparation of students (A2-B2)

Levels on the Common European Framework of Reference for Languages, the curriculum and the number of students	A2	B1	B2
1 course (94 students)	33	59	2
2 course (100 students)	24	65	11

The study of a future specialist's readiness for intercultural written communication in a foreign language is presented in two stages. In the first stage, students were offered a written assignment developed by the authors: writing a business e-mail in a foreign language. The second stage implied the analysis of business emails written by students, identification, classification and determination of the students' awareness of the peculiarities of business writing and their readiness to solve communicative and managerial tasks in the format of intercultural professional written communication.

In the practical task of the first stage, in order to identify the knowledge, skills and abilities of the test subjects required for successful professional written communication, we offered the students to write a business letter within a problematic situation. The task was aimed, firstly, at revealing the students' general understanding of the structure and format of business writing as well as stylistic features of business writing. Secondly, in writing, students were asked to demonstrate analytical and critical thinking skills to solve a communicative problem.

The second stage, which aimed to determine the readiness of students for intercultural professional written communication, was evaluated according to the following parameters, determining the degree of correctness of business text layout (high/medium/low): presence of the generally accepted structure of business writing in an electronic format, ability to solve a communicative problem, presence of markers of sequence and coherence of the text, presence of reasoned and logical presentation, lexical adequacy of presentation, grammatical adequacy of presentation, knowledge of punctuation and spelling rules, adequacy of presentation style, presence of unnecessary information in the text of business writing.

The overall task execution level was defined as follows: high, medium, low. According to the results of the analysis, the following levels of task fulfillment were established: high—86 to 100%, medium—60 to 85%, low—0 to 59%.

3 Results

According to the results of preliminary testing, the level of students' training corresponds from A2 to B2 on the Common European Framework of Reference for Foreign Language Proficiency/Common European Framework of Reference (Table 2).

The results of the test assignment to determine students' awareness of the features of business writing in electronic format and their writing skills showed that students can participate in foreign-language written communication. Almost everyone was

able to write a business letter and solve a communication problem to varying degrees (Table 3). The number of students who wrote a business letter, considering the generally accepted requirements for business correspondence, but with minor violations, was 26 (13.40%). 158 (81.44%) of the people coped with the task at a good level with some shortcomings, which generally does not interfere with communication. 10 (5.16%) students performed at a low level, which in some cases may lead to communication difficulties.

The analysis of completed written assignments showed that students are not sufficiently aware of the main features of writing a business letter and may have limited intercultural professional written communication in a foreign language. We consider the situation to be logical. The results obtained correspond to the general level of educational training of 1st–2nd year students and indicate the lack of special knowledge and professional experience. However, we note that the degree of students' readiness for this activity may be acceptable for further development of their existing foreign-language written communication skills in their senior university courses.

In general, students demonstrate knowledge and ability to adhere to accepted norms concerning the structure of business writing, to solve communicative problems, to use markers of sequence and coherence of the text, to present their thoughts in an argumentative, logical and adequate way when establishing and solving problems. With regard to the linguistic requirements for business letters, many works included full grammatical forms, passive voice, detailed and complex sentences that correspond to the official business style of written communication.

The assessment of the readiness of university students to participate in foreign-language written communication in an intercultural professional electronic format indicates that this study makes a definitely significant contribution to the international practice of diagnosing the level of written communication of future specialists within the boundaries of professional activity.

Table 3 Overall results of students' awareness and readiness for intercultural professional written communication in electronic format

Year of training and awareness and readiness level	High level	Medium level	Low level
1 year (94 students)	5	82	7
2 year (100 students)	21	76	3

4 Conclusion

The monitoring of students' knowledge, skills and abilities and the analysis of their readiness for foreign-language communication showed that not only linguistic difficulties, but to a greater extent the lack of special knowledge and low level of professional immersion in the process of intercultural foreign-language written communication create objective difficulties for them in performing their written tasks in electronic format.

By summarizing the results of students' awareness and readiness for intercultural professional written communication in electronic format, the basic methodological tools for constructing the educational process are determined. The essence and content of the revealed difficulties make it possible to clarify the idea of the communicative problem as a complex, multidimensional phenomenon that integrates difficulties of a linguistic, organizational and logical nature.

The authors worked out a model of the online course «Business» Contacts Across Cultures And Writing», the implementation of which allows us to expand the boundaries of educational activities of students and increase the effectiveness of vocational training within the framework of a higher educational institution.

Within the limits of solving communication tasks, the obtained data on the degree of students' readiness to participate in intercultural foreign-language written communication, assessment of the identified language and other difficulties in writing business letters provided substantial support in developing project tasks of a new format and additional training material for online learning. In our opinion, if additional information sections on global trends and processes of the digital economy, norms of business and professional culture of English-speaking countries in the modern world, rules of behavior communication, specifics of corporate documents are included in the training materials, we can count on more positive results of the training.

The main problem for many professionals in today's digital space is the inability to adapt to the communication format of their foreign colleagues and partners. It is important to understand that with the effective use of new communication technologies it is possible to achieve successful results, and with the ineffective use it is possible to significantly harm both the career of the author of correspondence and the reputation of their company.

Competently organized preparation for written communication in a foreign language and work with various documents can most successfully contribute to the professional implementation of graduates in the chosen field at the current stage of economic development.

Fluency in a foreign language, which is seen as an important tool for professionally oriented, scientific and social training of future specialists, as well as knowledge of the format of documentary texts and practical skills acquired during training will allow to adapt more effectively to foreign-language professional activity in modern conditions.

Acknowledgements The authors of the article express their gratitude to the reviewers of the journal for their attentive reading of the article, appropriate criticism that contributed to its improvement.

Counteraction to Dangerous Infringements on Children's Rights and Interests in the Information Sphere in the Context of the Digital Transformation of Management in Russia

Liudmila A. Bukalerova, Aleksandr V. Ostroushko, and Rosalina V. Shagieva

Abstract The relevance of the problem under study is due to the need for digital transformation of management in Russia in the context of improving the legal regulation of countering dangerous infringements of information rights and the insufficient development of theoretical, substantive, technological and scientific-conceptual aspects of the formation of a legal concepts base for their applicability in legal constructions. The purpose of the article is to develop scientifically sound and verified practice of terminology in the field of research on countering dangerous attacks on children's information rights and testing them for use in the course of improving Russian legislation and so on. The leading method for studying this problem is the formal legal method, which allows us to consider this problem as a process of deliberate and conscious mastering by children of knowledge, skills and abilities to carry out information and legal actions in the digital sphere only if their information security is fully ensured. The article presents the author's concept of digital rights and children's information interests; The scientific foundations of their implementation in the context of digital transformation of management in Russia are revealed. The developed theoretical provisions and proposals for improving the legislation are aimed at adapting minors to new conditions of governance in the information society and are focused on the development by the legal science and practice of scientific and methodological support for the legal regulation of counteraction to dangerous encroachments on children's information rights.

1 Introduction

The main feature of modern digital society, according to foreign scientists, is the integration of communications and other digital technologies in everyday life [1]. Along with the positive qualities of the new information society, quite serious problems have been discovered in the course of its formation. Unfortunately, negative behavior and abuse have become commonplace in the course of interpersonal contacts on Internet resources, especially in social networks, as well as through mobile phones and other electronic communication devices. New types of illegal acts that occur with the use of modern information technologies, previously unknown both to domestic legal scholars and world legal practice, which cannot be effectively counteracted due to the lack of carefully developed, coordinated, thought-out modern legislation, have become a reality.

An integral component of the process of transition to the information society in our country was the emergence of a complex of completely new rights and interests of minors, which are necessary for the realization of minors in their daily and educational activities. It is important that the exercise of information rights should be carried out in an environment that minimizes both existing and new threats and risks.

A number of studies conducted to date suggest that children and adolescents increasingly perceive modern information technology not only as an interesting and useful, but also as an unsafe environment [2–4]. Ensuring the universally recognized rights of children to protection from negative information that violates their moral, mental, physical, and social development is one of the priority areas of Russian state policy at the present stage [5]. The basic principle of this work should be the declaration of the creation of an atmosphere in the information environment free from negative impact on the psyche of children regardless of their social status, religious, ethnic and state affiliation [6, 7].

Our survey showed a high level of confidence of Russian citizens in the need to create a mechanism of protection against malicious information influence on children through telecommunications networks by improving the norms of current legislation. The existing legal mechanism for such protection of children is based on legislation adopted in various branches of Russian law and not always consistent with each other. Often, these documents were created as a matter of urgency to solve current problems, which led to these conflicts. In addition, the issues of improving mechanisms for preventing delinquent behavior of minors produced by the content of the Internet are relevant [8].

We believe that the creation of a legal mechanism to prevent the spread of information through telecommunications networks, which, based on the possibilities of social engineering and targeting technology to promote sites, is not aimed at the

transfer of positive and adequate basic concepts of the world and man to minors, but aims to desocialization, the denial of family values, the formation of social consumption and dependency, and the development and consolidation of deviant and illegal behavior among children, should be based on an increase in knowledge in domestic legal science about the creation of a comprehensive system of legal support for the information security of minors.

2 Methods

A big place in the work in connection with the stated research problems is occupied by the study of published scientific works of Russian researchers on children's information rights [9, 10].

The proposed methodological and analytical toolkit is a development of well-known and proven methods of research in legal science that allows you to create your own position on the studied issues. In order to conduct research, traditional and special methods of research and description of its results are used, in particular, formal legal, comparative methods, methods of classification of acts on various grounds, legal expertise, methods of interpretation of law, system and structural analysis and other legal analytical methods, which were repeatedly used by the authors earlier [11, 12].

3 Results

When considering children's information rights, it should be borne in mind that this list of subjective rights of minors is enshrined in various normative legal acts in a number of branches of Russian law. At the same time, legislation, such as the Russian Family Code, uses an additional definition of "the interests of children/minors" in addition to traditional rights.

Based on the interpretation of the Resolution of the Plenum of the Supreme Court of the Russian Federation of 20.04.2006 No. 8 "On the application by the courts of the legislation in consideration of cases on adoption of children", the interests of children should be understood as the creation of favorable conditions (both material and moral) for their upbringing and comprehensive development. Thus, children's interests in the information sphere imply favorable conditions for the realization of public relations established for minors in the information society under the influence of moral and ethical norms, which require the State to create a state of security.

We propose to consider **children's interests in the information sphere** as the rules of realization of social relations, which are not fixed by the law, and which have been formed under the influence of moral norms, foreign and world practice, common sense, etc., and which require the legislator to pay attention to this and to create conditions facilitating their realization during the law-making activity.

The most important interest of minors in the field of information is to develop their behavioral skills for safe work with communication devices and on the Internet. This requires appropriate regulation and should be included in educational programs by introducing the necessary competencies both in existing educational disciplines (currently—Principles of Personal and Social Safety) and by developing special new competencies for different age categories of children [12]. This is due to the fact that more than 90% of children under 7 years of age use technical devices that allow communicating with each other in the information space [13], and it is important to teach children to better communicate their ideas through various means of communication, including the Internet and others based on the use of modern mobile devices. These competences are equally important for adults working with children as well as parents to understand how their children coexist in the information space.

The main provision in this respect is the one stated in part four of article 29 of the Constitution of the Russian Federation that everyone has the right to freely seek, receive, transfer, produce and disseminate information by any lawful means. Traditionally, this set of powers has been referred to as the "right to information". The right to information was introduced into the Russian Constitution of 1993 in compliance with the requirements of Article 10 of the European Convention on Human Rights and is an important institution of Russian law.

Initially, the right to information was seen as a derivative right securing freedom to seek, receive and impart information, which served as a basis for a broad interpretation [14]. Over time, the right to information began to be seen as a right that was not a derivative but an independent right. The right to information is complex and includes a number of rights and freedoms (freedom of expression, freedom of the press, the right to form associations in the field of information, etc.).

The Constitution of the Russian Federation fully correlates with the postulates of Article 13 of the Convention on the Rights of the Child, approved by the UN General Assembly on 20.11.1989, which states that a child has the right to freely express his or her opinion; this right includes freedom to seek, receive and impart information and ideas of any kind, regardless of frontiers, orally, in writing or in print, in the form of art, or by other means chosen by the child. Article 17 of the Convention states that all States shall ensure that the child has access to information and material from a variety of national and international sources, especially those aimed at the promotion of the child's social, spiritual and moral well-being and healthy physical and mental development.

We support the opinion of A. S. Pigolkin on the urgent need to supplement the right to information with a number of other constitutional rights inherent in the information society, such as freedom of citizen access to information technologies and global information space, the right to protection of personal and other confidential information [15] 44).

At the same time, we don't share the idea that has become popular during the digital transformation of the economy and its management to reduce all human rights in the information sphere to the so-called "digital rights" [9, 16]. Contrary to the opinion that they exist, we are convinced that children's rights in this area are often exercised

not in connection with or regarding information that is doomed to digital (i.e., in the form of binary signals) form.

As for the term "digital rights", since October 2019 it has been used in the Civil Code of the Russian Federation to denote obligations and other rights, the content and conditions for the implementation of which are determined in accordance with the rules of the information system that meets the criteria established by law.

Thus, it is not correct to speak of any digital rights of children, meaning the constitutional right to information. In our opinion, it is acceptable to use the construction "**children's rights in a digital environment**"; these rights are one component of the whole set of information rights of minors.

The right to information is primarily associated with the right to access information. Article 2 of Federal Law No. 149-FZ of 27.07.2006 "On Information, Information Technologies and Information Protection" provides a legal definition that access to information is an opportunity to obtain information and use it. We can state that every child has the right not only to receive information, but also to receive appropriate information, and it is the duty of the State to ensure this right by all legal means at its disposal and to create a barrier to all available and potential sources of destructive, socially negative information.

New information technologies, combined with the low cost of devices with Internet access, have provided minors with almost unlimited access to information resources. The current state of affairs is characterized by a sharp increase in the level of competence of minors in relation to the possibilities of obtaining information, especially when working with the Internet and extremely low competence in the field of ensuring their information security. Such a conclusion allows us to make an analysis of already conducted research in this area [10, 11], as well as preliminary data obtained by the entrance to the questionnaire on a special program of parents, teachers and schoolchildren (students) "The level of awareness of minors in matters of personal information security".

Minors' low awareness of network security occurs when any subject who has access to the virtual space can provide any information, independently determining their direction and methods of distribution. At the same time, there is a paradoxical situation when a subject knows that information may be harmful to children, performs all the duties assigned to him/her on age marking and other restrictions on distribution, but this information will still be available to minors. A classic example of this is the remote sale of alcoholic beverages, sites of tobacco manufacturers, digital libraries and sites of audio-visual service, where in order to access information it is enough to click a button confirming that the user is above 16/18 years old.

We consider it wrong to believe that the right of access to information for minors is not subject to any restrictions. A child's absolute right to information contains the potential for violating the information rights of minors. The situation is aggravated by the fact that a child, due to his or her physical and mental immaturity, cannot fully report on his or her actions, "filter" the information provided to him or her, or criticize the actions of others aimed at him or her.

The European Convention on the Rights of the Child said that the exercise of the right to access information could be subject to certain restrictions, but those restrictions could only be those prescribed by law and were necessary:

- to respect the rights and reputation of others;
- for the protection of national security or of public order, or of public health or morals.

Naturally, parents take measures to protect their children from threats from the Internet. Their approach can be divided into two components: the direct impact on content, by installing special management and verification tools on computers, smartphones and other gadgets, or the indirect action of discussing threats with the child, as well as special warnings or parental advice.

However, resources on the Internet and a number of human rights defenders are actively promoting the idea that "parents have no right to restrict minors' access to information resources and deprive their children of access to the Internet". This is motivated by the fact that parents who grew up without the Internet and watched "bogeyman stories on telly" believe that the Internet is harmful. Communities are created in social networks, for example, "Children and Youth Liberation Movement of BZR (Struggle for Equal Rights)" and others. At the same time, with only a few dozen subscribers, BZR is not above using foul language on its home page.

Children should be trained to be critical of the media and, above all, the Internet and the media. We believe that information and media literacy training should be regarded as children's interest in the information field.

Minors are not only interested in receiving information, but also actively use the right to information components of the provision and dissemination of information. The law interprets these terms as follows: dissemination of information means actions aimed at receiving information by an indeterminate circle of individuals or transferring information to an indeterminate circle of individuals; provision of information is actions aimed at receiving information by a certain circle of individuals or transferring information to a certain circle of individuals.

The right of the child to express his or her opinion is provided for in article 29 of the Constitution and article 57 of the Family Code. However, there are many questions about the age at which a child has the right to express his or her opinion independently outside the family and make it publicly available, as well as the boundaries of a child's expression of opinion [17].

There is no doubt that the freedom of thought and speech for children remains within the limits defined by law until we raise the question of the age of the subject presenting their views. The parents (legal representatives), educators and teachers are the main moral guidelines for minors. The lack of critical thinking in preschool age actually taboos the vocabulary of a child defined by parents under threat of punishment or deprivation of any benefits [18].

Therefore, it's unreasonable to recognize cases when adults raising children restrict their access to a certain kind of information, as an encroachment on the freedom of thought and speech of a minor.

It is also a misconception that a child should not restrict themselves in the exercise of their rights, including the right to express their opinion, which contravenes article 13 of the Convention on the Rights of the Child, which provides for the restriction of this right where such restriction is provided by law and is necessary for respect of the rights and reputation of others and for the protection of national security, public order, public health or morals.

Some scientists consider children's actions in disseminating information on the Internet as a typical psychological paradox of the relationship between the mind (a set of abilities to think, cognize, understand) and advanced information technologies: the lack of real control over a teenager's socialization, which takes place mainly through communication on the Internet, may result in a complete loss of control over the formation of their model of behavior in society, which will entail a reassessment of values and, consequently, an unconscious transition to the commission of offenses [19].

Cases are known when parents did not realize their responsibility or on the contrary encouraged the child to create and disseminate information not corresponding to norms of public morals. Thus, according to a study by T. Y. Arkhireyskaya, it was revealed that there were more than 130 thousand views on YouTube in November 2017 of the video, where a little girl, with the active approval of her mother, expressed foul language against her grandmother. We believe that the law should have methods to influence such parents. According to a study conducted by South Korean scientists in 2018, it was parental neglect of their children's online activities that was observed among teenagers committing acts aimed at managing another person's social environment and destroying social ties through targeted manipulative and destructive actions that damaged the social status of the victim [20].

4 Conclusions

At present, the problem is that the laws adopted to ensure information security for minors cannot have a full impact on the current situation. The rapid development of the Internet leads to the fact that almost every minor already has free access to the Internet through an individual means of communication.

The State makes certain efforts to counteract the dissemination of certain types of information harmful to the moral health and development of minors in information and telecommunications networks:

1. Establishes restrictions on the dissemination of information on the Internet and other information distribution networks, and establishes legal liability for those who ignore these restrictions.
2. Sets out procedures for blocking or restricting access to sites containing information the distribution of which is prohibited by federal laws.
3. Monitors Russian legislation on the protection of children from information, encourages professional activities in the area of the mass media, etc.

However, we have to state that despite the introduction of serious measures to ensure information security of children on the Internet, the problems associated with the creation of a protected information environment are far from being finally resolved. The right of minors to information security, i.e. the protection of society and the State from types of information that threaten the life and health of children, is one of the priority rights of minors that has to be protected [21].

Legal and Organizational Peculiarities of Digital Transformation of Management While Ensuring Environmentally Sustainable Development of Moscow

Fyodor G. Myshko, Elena I. Mayorova, and Rosalina V. Shagieva

Abstract The relevance of the article is due to the introduction of the Digital Economy program in city management, which should bring the life of Russians to a qualitatively new level by 2024. There are legal prerequisites for improving the quality of life in cities using IT technologies. Digitalization improves the system of monitoring the state of the environment, makes it possible to ensure the sustainability of the ecosystem of individual municipalities and the city as a whole. An analysis of the existing system of environmental monitoring shows that it is not effective enough because it captures a large number of scattered indicators for various natural objects, but does not recreate a holistic picture of the state of the environment in a particular municipality. Software implementation of the municipal level geoportal can be carried out on the basis of the computing power and service equipment of the municipal formation or using SaaS-applications based on cloud technologies that provide the ability to use software products of the regional or federal level. As sensor technologies develop and spread, and their cost decreases, it becomes possible not only to connect each natural component to the observing system, but also to more effectively restore, create and transform urban natural objects. However, the shortage of IT specialists adapted to the biological field, the lack of biologists who are adept at computer technology, the insufficient training of people who have to work with new equipment, create obstacles to the introduction of digital technologies in the practice of creating a comfortable urban environment. The purpose of the article is to help overcome the traditional thinking of environmental specialists who prefer the usual means of visualization to modern methods of observation and evaluation, and to develop scientifically based and verified practice of new techniques and means for training specialists combining knowledge of IT technologies

and knowledge of the biological cycle sciences. The leading research method is the formal legal method, which allows us to consider this problem as a process of deliberate and conscious mastery of environmental knowledge, skills and abilities by specialists to carry out information and legal actions in digital form, subject to environmental safety and within the framework of the law. The article presents the author's solution of environmental problems on the basis of the implementation of an automated exchange between interested subjects: territorial bodies of federal executive bodies, local governments, property administrations. Theoretical principles and proposals have been developed to improve environmental legislation and environmental education, aimed at intensifying the training of IT specialists adapted to the biological field, biologists capable of working with computer programs and applications, i.e. people who have to service new equipment to introduce digital technologies into the practice of creating a comfortable urban environment.

1 Introduction

Economic reforms carried out in the modern history of Russia require the abandonment of routine management techniques and the transition to innovative methods of information collection and storage. It is difficult to name an area of life of the modern person where digital technologies would not penetrate. The digital economy, digital transformation of production, IT-medicine, "smart agriculture" are being created. In the field of housing and communal services, digitalization is also finding more and more applications. Russian Prime Minister's Order No. 1632-r of July 28, 2017 approved the program "Digital Economy", which, according to the plan of the government, will change the approach to the use of digital resources to transform the work of all organizations and take the life of Russians by 2024 to a qualitatively new level.

Creating a comfortable environment for urban conglomerations is a crucial area of strategic planning for the development of the country's municipalities and regions. In this regard, the role of an essential component of urban space—the natural, biological one—is growing. The urban environment, with its ambivalent biocoenotic links, is a highly complex entity that needs to be protected and has many indicators to consider and reflect on. Now, there have been several main documents of federal and municipal level developed and adopted, aimed at improving the quality of life of citizens. Concentration of population determines not only the problems of energy, transport, social and other types of urban systems development, but also leads to the deterioration of biological elements of the environment—greenery, soil, air, and to a decrease in biodiversity. Decrease in the quality of the biological component of settlements negatively affects the health of citizens. In addition, humans, as a

social and biological object, are just as degraded by negative external influences as, for example, vegetation. The desire of the residents of a municipality to live in a natural environment is the most important criterion for creating a favorable urban environment.

As a legal basis for the formation of a comfortable urban environment serve the following multi-level programs—the Federal Program "Formation of a comfortable urban environment", Municipal Programs "Formation of a comfortable urban environment" in 2018–2020; Priority Project of the Government of the Russian Federation "Housing and utilities and urban environment"; Program for the Formation of a Favorable Environment for Human Activity. These documents are directly related to the development plans of municipal entities and regions of the country and are designed to contribute to the improvement of quality of life of citizens. All regulatory legal documents adopted in recent years are oriented towards the sustainable development of the territories. The concept of sustainable development, put forward in 1987 in the report "Our Common Future" of the UN World Commission on Environment and Development and thoroughly forgotten in Russia, comes to the fore again. The implementation of this concept is inevitably associated with the preservation of the biosphere and natural capital [1]. The model of sustainable development of resource use is designed to enable people today to meet their needs while preserving the environment so that the needs of future generations can be met [2, 3].

2 Methodology

The methodological and analytical toolkit used by the authors is represented by well-known and proven in jurisprudence research methods and means. In order to obtain reliable and substantiated conclusions, traditional and special methods of research and description of its results are applied, in particular, formally legal, comparative methods, methods of analysis of normative legal acts, methods of interpretation of norms of law, system approach, etc., which were successfully used by the authors earlier [4–6]. Efficiency of the mechanism of legal regulation of the investigated sphere is defined from the point of view of detection in the current legal system of overlapping and redundant provisions of regulations, conflicting law enforcement practices, conflicts and legal gaps.

3 Results

The ongoing digital revolution makes it possible to use digital information and communication technologies to manage all systems of the city, improve the quality of life of citizens, and mitigate the stress of urbanization. In recent years, economic formation has changed, with a strong emphasis on preserving and even reproducing

the environmental component of the economy. Digitalization provides an opportunity to ensure the sustainability of the city ecosystem, to change the relationship between people and the environment, to develop the economy through the greening of the existing one—the development of a green economy.

Paragraph 3 of Article 1 of the Town Planning Code of the Russian Federation defines sustainable development of territories as "ensuring safety and favorable conditions for human activity in the implementation of urban planning activities, limiting the negative impact of economic and other activities on the environment and ensuring the protection and rational use of natural resources in the interests of present and future generations". However, some geospatial, environmental and analytical information on the state of all urban life support systems must be available before any organizational activity can be planned. This is facilitated by the environmental monitoring system established in the first decade of the twenty-first century.

Federal Law of January 10, 2002 No. 7-FZ "On Environmental Protection" contains the legal concept of state environmental monitoring: "it is a comprehensive monitoring of the environment, including the components of the natural environment, natural ecological systems, processes occurring in them, phenomena, assessment and prediction of changes in the state of the environment". In accordance with Article 63.1 of the Act, the mentioned procedure is carried out by "federal executive bodies exercising state administration in the field of environmental protection, federal executive bodies authorized to conduct subsystems of the unified system of state environmental monitoring". Environmental monitoring is also conducted by the relevant authorities of the constituent entities of the Russian Federation. On the part of federal executive authorities, state environmental monitoring is carried out by the territorial body of Roshydromet—the Federal State Budgetary Institution "Central Department for Hydrometeorology and Environmental Monitoring" (FGBU "Central UGMS"). Law of the City of Moscow of November 20, 2004 No. 65 "On environmental monitoring in the city of Moscow" (current edition) has established the objectives of environmental monitoring, the procedure of work implementation and the main directions for using the data obtained. The Unified City Fund of Environmental Monitoring Data is an ordered, constantly replenished set of monitoring data, as well as information on the state of the environment on electronic and other media, obtained through the collection, processing and analysis of environmental monitoring data. Regulation on the Unified City Fund of Environmental Monitoring Data defines the procedure for creating and maintaining the Unified City Fund of Environmental Monitoring data, as well as the composition and structure of information on the state of the environment, the order of its acquisition, accounting, storage, use and provision.

Moscow, as a constituent entity of the Russian Federation, has the authority to create its own system of environmental monitoring, including observations of the state of atmospheric air, surface water bodies, soils, green areas, noise levels, hazardous geo-ecological processes. The head organization carrying out these observations is the State Budgetary Institution "Mosecomonitoring". It also forms the Moscow-owned Single City Data Fund.

Since 1996, the monitoring of Moscow's atmospheric air quality has started, which is the most important aspect of the information on environmental safety of the capital's residents. The information comes from 56 automatic air pollution control stations (including the mobile ones) located in all districts of Moscow near pollution sources of different intensity: highways, industrial enterprises of high danger, as well as in residential and natural areas. The data are collected continuously and the control panel receives data every 20 min.

Due to lack of powers of the constituent entities of the Russian Federation in terms of state monitoring of water bodies, monitoring of surface waters in Moscow is carried out within the framework of environmental control over activities of water user enterprises. In addition, departmental control of water quality in water outlets is performed. Information flows of data on the quality of natural and waste water received by water user enterprises, as well as data on water sampling in discharges received as part of inspections of the Environmental Management and Protection Department of the city are recorded. The number of observation points (intake points) reaches almost 70, their number is quite evenly distributed throughout the main water artery of the capital—the Moscow River, its large tributaries and small rivers of the city. 40 water indicators are analyzed, including the content of chlorinated substances, salts of nitric acid (nitrite, nitrate), heavy metals and other substances hazardous to human health.

There was no unified soil quality surveillance system until 2004. The urban soil is intensively degrading—it is not only getting clogged and sealed, but also accumulating a lot of pollutants. Pursuant to Resolution No. 514PP of the Moscow City Government dated 27 July 2004 "On Improving the Quality of Soil Cover in Moscow", a regular examination of the soil cover of administrative districts and functional zones and the city was organized. Environmental monitoring of soils and potting soils to exceed the TLV of harmful substances, as well as the content of organic matter, macronutrients, etc. is carried out at almost one and a half thousand permanent sites.

Experience in implementing monitoring of green spaces was conducted during the years of perestroika by the first joint Soviet-Italian ecological enterprise "Prima-M" and continued from 1997 to 2005. All information was processed and stored in a computer database. An analytical report with conclusions and recommendations was issued annually based on the monitoring results. But then the project was shut down, apparently due to the reduction of the territory occupied by green spaces - they were voluntarily allocated for commercial construction. Nevertheless, in accordance with the Moscow Government Resolution No. 328-PP dated May 17, 2005, the information and reference system "Green Monitoring" has been developed, which summarizes and systematizes the actual material on the state of green spaces in the capital. In this way, observation data are compactly stored, processed and analyzed, and can be provided on demand.

Almost all orders and decrees of the Moscow City Government on greening are formed on the basis of monitoring data. A citywide program of inventory of green areas is being implemented, and their City Register is being created. Global practice is moving away from opposing "green spaces" to other natural objects. The

complex term “green infrastructure” is relevant. Our country has not developed criteria to assess the effectiveness of green infrastructure in cities. There is even no legally defined concept definition of this notion [7], which certainly requires increased attention to the revision of existing views.

All studies of the noise level in Moscow unequivocally prove that most of the city’s residential areas are in a zone of noise discomfort. The source of noise are all types of transport—from cars to planes—industrial enterprises, numerous construction sites. The problem of increased noise impact is relevant for all big cities. EU Directive 2002/49 of 25.06.2002 of the European Parliament and of the Council defines urban noise pollution as one of the main problems of negative anthropogenic impact on the environment in Europe. Noise pollution in a megapolis can be considered as environmental pollution. Noise is monitored in order to develop measures to reduce it.

In Moscow, due to the size of the territories of its municipal entities, the relative diversity of geological and climatic conditions, areas with a complex topography increasing loads on the ground, the saturation of underground communications, etc., the requirements for monitoring the safety of all related elements of life support increase. Geo-environmental monitoring is a system of regular observations of the state of the subsoil and the processes occurring in it. The main activities of the section are: monitoring of underground water conditions through a network of wells at the territorial level (in accordance with the powers of a constituent entity of the Russian Federation); monitoring of anthropogenic shifts: landslides, karst and karst-suffosion processes.

In the aspect of the study, we can state that the set of data obtained from the monitoring of all natural components of the urban environment: atmospheric air, green areas, water, soil and underground space makes it possible to determine the degree of deterioration of their condition. This, in turn, may be the basis for decisions to reduce the anthropogenic load on a particular element of urban territory. The current system of environmental monitoring allows to inform the population about air pollution; to track sources of noise impact, to reveal soil pollution on 18 indicators; to establish habitats of animals listed in the Red Book of Moscow; to analyze the condition of urban green spaces and specially protected natural areas and plan conservation activities in protected areas.

The probability of an emergency at any site due to the wear and tear of engineering networks is increasing day by day. Thanks to the possibilities of digital transformation of management, an effective system of multifunctional monitoring network of engineering communications of urban real estate condition has been formed: residential, industrial buildings and structures, as well as transport infrastructure. Control over the environmental component, an important element in ensuring a favorable environment for citizens, is much less formalized. However, any negative impact on the environment along with a direct threat to the popularity and infrastructure facilities is detrimental to the biological framework of the city: green spaces of various categories, urban waters, soils. In this regard, the development of methods to monitor negative environmental impacts is very relevant. They exist and have already showed their high performance. For example, in connection with the introduction of

modern technologies, a breakthrough is planned in the field of waste management of production and consumption. Most waste bins are equipped with the GLONASS system.

Therefore, solid municipal waste, which used to be often dumped in suburban forests, began to be transported to landfills much more often.

Up to now visual observation of biological objects is the most usual and—it should be admitted—quite effective means of detecting negative anthropogenic and technology-related impact on biological objects. But with the increase of the research area and options for the degradation of the biological habitat of citizens, traditional methods are becoming insufficient. As IT-technologies develop, space imagery using remote sensing data is successfully used for solving problems in land use, agriculture and forestry, and is increasingly used to detect problem zones in cities. The structure of ecological monitoring of the natural environment and the information-reference and analytical computer program of estimation of its separate parameters, collection, storage and processing of materials of the research is developed.

In 2014, the Government of the Russian Federation approved the Unified State System for Prevention and Elimination of Emergency Situations. It was adopted to solve the problem of formation of technical and software means of the complex "Safe City". It requires the creation of a comprehensive multilevel system for ensuring public safety, law and order and habitat security, based on modern approaches to monitoring, forecasting, prevention and response to natural and man-made crime, accidents and emergencies at the level of the constituent entity of the Russian Federation and the municipality. The System sees environmental safety as an inalienable part of overall safety. Along with solving global tasks in the field of urban ecology, the improvement of the system can be aimed at preventing and eliminating environmental risks in a particular area and thus optimize the environment of a particular municipality [8]. In theory, where there is no way to prevent environmental damage, the system may recommend immediate action to compensate for it. Such a necessity may arise in case of local damage to the ecological object—for example, illegal felling of the green area may be to some extent replenished by compensatory planting. In case of lack of any information about the object of study, the effectiveness of its use is significantly reduced. Only an increase in the number of indicators taken into account will make it possible to control the environmental situation in large cities and to develop and implement a system of environmental protection measures to improve the quality of habitat. The video surveillance system "Safe City" created with the development of the Unified State System for Prevention and Elimination of Emergency Situations allows not only to monitor in real time the situation in the city and respond quickly to emergencies, but also to identify various violations, such as the creation of illegal dumps, sealing the soil, etc. Using digitalization methods and techniques it is possible to identify degraded zones by monitoring green "Big data", including online screening of a whole range of profile indicators [9], which are so necessary for the further restoration of ecological systems.

The expansion of the information sector through the digitalization, the improvement of information and communication technologies (ICTs), and their widespread use are leading to significant changes, including in the environmental sphere. This

is also a significant facilitation of access to information resources, both in terms of time costs and the ability to solve the problem, taking into account the volume of information relevant at the time of the study and available in territorial and temporal parameters [10]. Large state structures of the Rosreestr (The Federal Service for State Registration, Cadastre and Cartography) subdivision, cartographic funds of different levels, parts of the Topographic Service of the Armed Forces of the Russian Federation are engaged in creation of digital maps of cities, processing of remote sensing data, forming height matrixes and terrain models in industrial volumes. Applications of remote sensing of the Earth using global navigation satellite and geoinformation systems—GLONASS, "Rapid Eye", "CORINE Land Constellation" satellites – become commonplace [11, 12]. As a rule, spatial information in the data bank is kept in a single exchange format, and when issued to the consumer it is converted into the required format if necessary. Software implementation of a municipal level geoportal can be carried out on the basis of computing capacity and service equipment of a municipal entity or using SaaS applications based on cloud technology, providing an opportunity to use software products of regional or federal level [13–15] .

4 Conclusions/Recommendations

Creating a digitized data set is not the end goal of the digitalization process. To solve nature protection tasks, it is expedient to implement an automated exchange between interested subjects: territorial bodies of federal executive authorities, local self-government bodies, object administrations. Accordingly, it's important to determine, who will be the system administrator of a shared information cloud, shared protocol and shared digital platform? Lack of IT specialists adapted to the biological sphere, lack of biologists with adequate knowledge of computer technologies, insufficient training of people who will have to work with new equipment create obstacles to the implementation of digital technology in life. For example, it has been found that the death of green spaces may have been due to several mutually exclusive causes: (1) application of anti-icing reagents, which resulted in soil salinization; (2) contamination of the air and the very soils, especially near highways; (3) compaction of soils as a result of anthropogenic and other loads; (4) sealing of circles situated near tree trunks with asphalt or concrete. Who should professionally state the specific cause of plantation destruction?

Thus, the following problems emerge:

1. Traditional thinking of environmentalists who prefer time-tested habitual means of determining the state of various biological objects in the urban environment to modern methods of observation and evaluation.
2. Insufficient adaptation of information systems to non-standard practice requests.
3. Lack of specialists, combining the IT-competence and knowledge of biosciences.

This situation requires improvement of the higher education system. It is necessary to give trainees not only professional knowledge, but also a full set of necessary super-professional skills. To this end, new educational approaches and learning tools should be introduced into the training of specialists in the relevant field [10]. The speed and competence to address these issues largely determine the effectiveness of activities to create manageable sets of environmental data needed to build a comfortable urban environment. Digitalization of monitoring data on the environmental components of the urban environment is not a technology or a product, but rather an approach to using digital resources to transform environmental activities. Designed to make each person's life better and more comfortable, digitalization can ultimately contribute to the creation of a common safe living space in cities.

Regulation of Migration Processes in Russia. Study with Regards to the Standards of Human Rights Protection and Minimization of Risks

Sergey Yu. Belokonev, Marina E. Rodionova, Vadim V. Zubov, and Dmitriy A. Ezhov

Abstract *Purpose* theoretical and methodological interdisciplinary study of migration regulation methods taking into account the global trends of development and practice-oriented strategic modeling, empirical migration indicators. *Design/methodology/approach* the methodology of study is based on the polyparadigmatic concept of interdisciplinary research using scientific and practical experience in studying the migration processes and the practice of possible impact on their regulation. *Findings* the methods of study were developed, namely sociopolitical forecasting of migration risks, ranking of sociological and politological indicators of migration processes, typification of immigrants. A comparative political and legal model for adaptation/integration of immigrants was developed taking into account the methodological approaches to regulation of the migration processes in the Russian society, country-specific approaches and international standards for regulation of migration, as well as the mechanisms of human rights protection and the tasks of migration risks minimization *Originality/value* The scope corresponds to the optimization of legitimate instruments of state, municipal and public regulation of sociopolitical problems related to harmonization of the interests of civil society strata within the regions of the Russian Federation. *Predictive proposals for development of the object of study*: it is advisable to monitor the level of regional conflictogenity; an analysis of the migration processes regulation and migration management can be used to develop the model legislation of the CIS member states, as well as to implement the provisions of the Global Compact for Safe, Orderly and Regular Migration in the Russian Federation.

1 Introduction

This chapter presents a study of the adaptation process of the foreign citizens, who are an important object of the state migration policy of the Russian Federation; the influence of local governments and civil society institutions on the regulation of the voluntary inclusion of immigrants in the new social, economic and sociocultural environment of the Russian society.

At the end of the 20th century, a system approach to the study of migration processes gained traction abroad. The approach was first applied to analysis of international migration by such researchers as Fawcett et al. [1, 2], who applied the system approach in the study of global processes that affect migration. Migration processes in the global context are considered by the representatives of this approach with regard to the political, cultural, economic, social characteristics of the recipient countries and regions. Among the Russian researchers, a range of works by Savoskul [3] should be noted.

In Russia, the migration and demographic approach has gained fundamental traction in practice, whereas this approach focuses on addressing the urgent problems of immigrant integration in the territories of the Eurasian and Asian regions, and analyzing the socio-demographic consequences of migration processes for the development of Russia and foreign countries. For instance, the researches by Rybakovsky [4, 5] are based on a phased analysis of the migration process: (1) the initial stage of preparation, during which the migration mobility is formed; (2) the process of population movement itself; (3) the process of migrants adaptation to the new conditions in the territory of their settlement or in the country of entry. The criteria for determining the migration potential of countries of the new foreign countries for Russia. Stratification of the Russian population was developed with regard to the migration potential in foreign countries, including the compatriots. The systemic sign for determining the migration potential for a scientist is the size of a certain population, formed directly by ethnicity, or in conjunction with the linguistic or geopolitical component. [6] With the adoption of the Concept of State Migration Policy, L. L. Rybakovsky correlated its goals, objectives and directions with the demographic policy, proposing to establish the threshold values, complex tasks, special regional and federal programs. He proposed three directions of the demographic policy: fertility, mortality and migration. The characteristic of factors influencing the effectiveness of the demographic policy was given; its regional specificity was analyzed. According to the scientist, the eastern vector of demographic development is the priority for Russia, given its natural resources and geographical advantage (the Trans-Siberian route).

2 Materials and Method

The chapter uses the research methodology of comparative stratification assessment of the Russian civil society according to the criterion of subsidization and non-subsidization (independence) of the regions, which was developed by G. G. Sillast. This technique is used in the study to assess the factors building up the state migration policy in the field of reception and distribution of immigrants, including the compatriots living abroad.

Typification of immigrants is necessary for further classification of the statistical indicators of the migration processes regulation, their qualitative assessment in order to create, at the final stage of the study, a mathematical model for coordinating the institutional indicators. This technique can be used as a basis for software designed for monitoring and forecasting the migration processes in Russia.

Scientific approaches to the study of the issues related to the migration processes regulation can be systematized by the methodological approaches of the researchers [7–15]:

1. Migration and demographic approach, which is represented in the Russian Federation by the works of L. L. Rybakovsky, S. V. Ryazantseva, whose attention is focused on the problems of international integration and migration of the Eurasian and Asian regions, the sociodemographic consequences of such processes for the development of Russia and foreign countries.
2. Institutional and legal approach, from the perspective of which the practical methods are developed for implementing the state migration policy of the Russian Federation, ensuring the infrastructure of labor migration, the legal status of a foreign migrant (stateless person or compatriot) living abroad, as well as technology for preventing migration risks and threats. This scientific approach is represented by V. A. Volokh, A. B. Paskachev.
3. Sociological approach, which considers migration as a social macro-process and a phenomenon, reflecting the social interaction of migrants as a specific sociodemographic group with a system of social institutions, communities and individuals at the institutional and interpersonal levels in the process of territorial movements, adaptation, migration mobility and change of status. From the standpoint of the sociological approach, the migration processes are described in the scientific studies by L. L. Rybakovsky, G. G. Sillaste, E. E. Pismennaya, V. I. Perevedintsev.
4. From the standpoint of interethnic and interethnic conflictology, which reveals the sociocultural peculiarities of the migrants integration into the system of social relations in the Russian society, the problems of migration xenophobia, the questions of interethnic and interethnic harmony are studied by V. I. Mukomel, L. M. Drobizheva.
5. Ethnical and politological approach, which focuses on the study of improvements in the state national and ethnic policies, the study of the sociopolitical phenomenon of interethnic conflicts, widely used in the works by V. Yu. Zorin.

6. Migration regional studies, specializing in the study of uneven financial, socioeconomic development of the territories, population decline in the regions and performance of the region-forming social institutions. This direction is being developed by the Institute of Socioeconomic Population Problems of the Russian Academy of Sciences under the guidance of E. S. Krasinets.
7. Post-crisis migration riskology, which analyzes movements of the migratory-active population from the migration donor states, the harm caused or the threat of negative consequences due to the national, regional, international crises, risks and threats to the recipient state. This direction includes the works by M. L. Galas.

Based on studies conducted by the Russian Public Opinion Research Center (VCIOM), a secondary analysis of the outcomes of studies of the relevant social indicators was carried out. The questionnaire array and empirical information was processed using the SPSS program to obtain a simple linear distribution (in percent), using correlation analysis and determining two- and three-dimensional dependencies. Migration processes, the level of political loyalty, the level of economic well-being of the region, the region's involvement in the commodity economy, social tension, and industrial orientation of the region were sociologically measured in the regions of the Russian Federation.

3 Results

A technique is proposed for calculating weighting (qualitative) coefficients for an indicator using the corresponding formula. For the purposes of evaluation, there is enough information about the current state of significant indicators, and for the quick evaluation, it is enough to use the trigger-type assessment of the state (good/bad, positive/negative, etc.) reduced to a numerical form, instead of the quantitative values of the selected indicators.

As a result of the study:

- a dynamic change in the modern migration process in terms of social, vocational, goal-setting indicators, indicators of law-obedience among the immigrants, their regional and geographical position and the level of tension (instability) in the country of origin was diagnosed;
- an integrative sociological approach was applied to studying the risks of migration processes in Russia;
- deformations in the distribution of migration flows in the regions of Russia, as well as their distribution by areas and types of activity, employment, qualification and professional clusters, as well as the presence of a destructive migration component, which creates risks for the social stability of migratory-attractive regions, were identified;
- it was substantiated that the risk of negative consequences expansion and potential social destabilization in the regions (primarily, migratory-attractive regions) due

to inadequate regulation of the migration flows remains in a latent state, but with increasing social dissatisfaction among the population, mostly with the quality of life and growth, it can reanimate such risks of social destabilization and generate conflicts intensively in the migratory-attractive subsidized regions;
- attention is drawn to the influence of the goal-oriented self-identification of immigrants, the types of their social interaction with the strata of the host civil society, the activity aimed to maintain their national identity, the formation of social ties by the foreigners in the regions of Russia and the intragroup stratification of such people;
- the influence of economic, social, financial, customs and tariff, tax, law enforcement, cultural and educational policies of the state on the migration flows was determined;
- on the example of migratory-attractive regions of Russia, taking into account their subsidization, financial and economic independence, the relationship between the migration risks and social stability of the constituent entities of the Russian Federation is shown, using the sociological indices of compliance of the proposed "statements of a life situation" and the likelihood of mass protests, stability in the Russian regions, well-being of the population, citizens' loyalty to the federal and regional authorities, performance efficiency of the regional authorities, etc.;
- the mechanism of interaction between the state bodies in the Russian regions and the civil society institutions in addressing the urgent issues of migration management was studied.

4 Conclusion

Analysis of the conceptual framework of the migration processes regulation has shown that it is important for Russia to optimize the migration risk management system that prevents the adverse impact of the migration component on the socioeconomic sphere of the country, the quality of life of the Russian citizens, since their interests are priority for the modern state migration policy, as well as the protection of the national labor market, amity in the Russian society.

For building up this effective migration management system, it is proposed to:

- set forth the quantitative and qualitative indicators of migration in the strategic planning documents, develop critical threshold indicators of the migration burden on the society (with the development of appropriate models and forecasts);
- while making decisions relating to the migration policy, to take into account the change in the genetic properties of the population as a result of mass migration (for example, by studying the genetically-determined predisposition to certain diseases)[1];

[1]Demographic genetics predicts how the number of, for example, patients suffering from any diseases with hereditary predisposition, including socially dangerous diseases (tuberculosis, hepatitis, AIDS, etc.) will change. Ecological genetics enables to predict the survival of migrants in

- develop a mechanism and legal framework for increasing the mobility of domestic Russian labor resources through identification of risks and urgent problems in this area and proposing the necessary solutions;

Mutual visa-free entry regimes, preferences and equal opportunities of employment, other areas of professional occupation, social guarantees, the gradual formation of a single economic space within the Eurasian Economic Union while maintaining tensions (instability) in the CIS countries in the medium term, suggest that Russia will remain to be the country of high migration attractiveness for CIS citizens and compatriots.

Governmental authorities, law enforcement agencies, courts, public associations in the member states of Eurasian Economic Commission (EEC), CIS member states, being the active migration donors and countries of origin of irregular migrants and persons without any specific legal status and, respectively, with a tendency to criminalization, should take measures to bring such citizens to responsibility, as well as those involved in organizing illegal migration and violating the rights of labor migrants.

At the same time, it is necessary to proceed with the joint activities among the CIS institutions, primarily the CIS IPA, to unify the framework of categories and concepts and labor legislation of the EEC member states. It is possible to hold expert-public discussions on labor migration issues among the EEC, CIS, and the Union State in order to develop common approaches and tools for harmonizing the interests of various socio-demographic groups of the population.

The informational support of the domestic and international migration policies will be facilitated with the communication strategy of EEC and CIS member states. Within the framework of this strategy, it is possible to develop the targeted information campaigns coordinated at the interstate level and aimed at comprehensive authentic and tolerant coverage of labor migration, resettlement of compatriots, etc.

It is essential to enact a legal act by the Ministry of Internal Affairs of Russia, which would establish the mandatory requirements to the draft state programs of the Russian Federation in the field of migration, which are developed by the Ministry of Internal Affairs of Russia, or submitted for approval by the Ministry of Internal Affairs of Russia, or considered by the mentioned ministry proactively, as well as to the draft state programs of the constituent entities of the Russian Federation in the field of migration, which are submitted for approval by the Ministry of Internal Affairs of Russia. Among other things, these requirements should contain an indication of the need to determine the objectives, main activities, target indicators and expected results of the programs with reference to the above areas of development and implementation of state policy and statutory regulation in the field of migration.

Analysis of judicial practice conducted by the Supreme Court of the Russian Federation in collaboration with the Office of the United Nations High Commissioner for Refugees showed a number of cases of non-compliance with the refugee rights.

---

new environmental conditions. Timely planning can take into account the nature and extent of the specialized medical care, targeted training of healthcare professionals in the most important areas, the peculiarities of consumption and nutrition.

For instance, refugees and members of their families who arrived with them to live in the Russian Federation cannot undergo the registration procedure at their place of residence, since they are not the owners of the dwelling. One of the possible ways out of this situation for people of this category is to establish the fact of residence through judicial proceedings. This situation requires improvement of the legal mechanisms for refugee registration.

Digital Transformation of the Educational Process in University in the Context of Globalization

Maria N. Belousova, Vitaliy A. Belousov, and Larisa V. Narkevich

Abstract As a result of the research the following spheres of influence of virtual environment on the university were defined: professional, environmental, functional. Exogenous and endogenous factors of information and communication technologies affecting universities were identified. In order to increase the efficiency of the educational process in the university it was proposed to introduce SMART-complexes of disciplines. The structure of SMART-complexes of disciplines is established, consisting of the following modules: definition of the level of learning, assessment of learning efficiency, content for adaptive learning, tasks for adaptive learning, a set of databases for storing learning profiles, a knowledge base with a mechanism for logical output. Detailed components of the educational SMART-complexes guide students in their learning activities to correctly find the tasks that are most appropriate and necessary at present, to effectively define strategies and methods of learning, taking into account their personal factors. A methodology for assessing the digitalization level of a university based on fuzzy logic as a tool for managing processes of the digital transformation of the educational process is proposed. The following groups of indicators were identified to assess the digitalization level of the university: digital literacy of teachers, digital literacy of students and digitalization of the educational process. Assessing the digitalization level of the university will reveal the strengths and weaknesses of the educational process, justify the necessary effective management decisions. The main directions of state policy for digitalization of education have been defined. The need to create a comprehensive national system for the development of digital literacy, combining the efforts of academic and non-formal education on the basis of public-private partnership has been stressed. The most important function of traditional higher education institutions remains

1 Introduction

The world community at the beginning of the third millennium is characterized by a number of features: the increasing importance of intellectual work, the use of information resources on a global scale; rapid exchange of data among experts, social and professional groups, communities of people, etc.

In accordance with the needs of our time, rapid growth of knowledge requires the introduction of new approaches to the organization of education and the search for innovative forms of transfer and acquisition of knowledge and competencies. Accelerated development of digital technologies stimulates the creation and introduction of innovative forms of education capable of keeping up with changes.

2 Methodology

The study analyzes various sources devoted to the problems of digital transformation in higher education, integration of SMART-education technologies into higher education, which include journal articles in leading peer-reviewed Russian and foreign periodicals, Internet resources.

The works of domestic scientists are devoted to the problem of assessing the digitalization level of universities and the readiness of Russian higher education for the digital economy [1, 2]. The use of fuzzy methods for assessing the digitalization level of universities requires further development.

3 Results

Today, both educational systems and employers are faced with the fact that digital age children will soon be applicants and job seekers. Generation Z and Millenials are connected to the global Internet and will be one of the first full-fledged users of the results of the Fourth Industrial Revolution. Thus, the impact of digitalization on universities is worth considering in three planes:

- Professional—new professions, new competencies;

- Environmental—a new worldview, a new lifestyle;
- Functional—new forms and methods of training.

At this, each of the areas presents challenges and opportunities for higher education institutions. Soon mass open online courses with certificate system will create serious competition for diplomas and certificates. In any case, it is worthwhile to model the relationship between employers and employees in the future when planning transformations in the education system.

According to a report by DELL Technologies and the Institute for the future "The next era of human-machine partnerships: emerging technologies" "impact on society & work in 2030" [3], it is expected that instead of waiting for staff to do most of the work, "work" will choose the best resource to complete it. Reputation assessment systems, data visualization and intelligence analytics will make it possible for people and businesses, institutions or organizations to find the best option at the discrete level of the work task.

All these tendencies cause and actualize new challenges for higher education, which should provide students with: synthesis of formal and non-formal (distance education), multidisciplinarity of specialties; constant updating of the content of academic disciplines and implementation of new tools and approaches to improve the quality of teaching; formation of a system of knowledge "soft skills", research skills, development of their own careers and the like; disclosure of cognitive abilities to learn; the engagement of world-renowned mentors in the learning process.

Analysis of the vacancy base and CVs [4] showed that there are 5 most common soft-skills. They overlap in both vacancies and resumes. These are personal characteristics and skills: creativity, willingness to learn, stress resistance, multitasking, ability to work in a team.

The most demanded quality specified in vacancies is resilience. It, as an important personal characteristic, was mentioned by companies in 37% of cases. Managers are also interested in 131 employees who know how to work in a team and can think creatively. If we talk about soft-skills in terms of professional fields, the ability to work in a team, as well as stress resistance is most often expected by employers in the retail sector. Multitasking is equally demanded in such industries as senior management, IT, marketing, human resources management and sales [4]. The question remains whether modern educational programs meet the needs of employers. After all, in the curricula of many educational institutions little attention is paid to the acquisition of soft-skills. This is often neglected, with particular attention to the cycle of profession-oriented disciplines. The analysis of foreign experience [5–7] in the implementation of educational activities has shown the expediency of involving stakeholders in the development, implementation and execution of educational programs. The result of such close cooperation will be the preparation of higher education standards for all first and second level higher education programs, which are an integral part of the system of internal quality assurance of educational activities and quality of higher education, and take into account all recommendations and requests of practitioners in training graduates. Such systematic integration of efforts of teachers, scientists and practitioners will contribute to the development and content of curricula according

to international standards, as well as to further professionalization of educational programs of the university.

In today's information society, expectations and requirements for higher education and universities are changing. The exogenous (external) factors of ICT influence on modern universities include the following:

- new expectations from universities, particularly the development of new competencies needed in the information society and critical thinking skills;
- the rapid growth of knowledge about society, nature and human;
- dynamism of knowledge, emergence of new professions and skills lead to the need to acquire knowledge throughout life;
- emergence of mass online courses that can be taught both at a specific university and outside it, but which, in essence, constitute an alternative to traditional university education and challenge it with their ultra-short lectures and interactive communication of participants;
- rating of universities, given their presence on the Internet and the citation of scientific works;
- strengthening of control over the activity of higher education institutions (applicant databases, database of graduates who received diplomas; online information on licensing of educational institutions, etc.);
- internationalization of the educational space and international mobility of subjects of the educational process (conferences, professional forums, working and training internships, training, exchange of experience).

Among the endogenous (internal, such as those related to pedagogical technologies) factors of ICT influence on modern universities, we will highlight the following:

- change in the formats of correspondence education, which is becoming a distance education, supported by the latest technologies: webinars, online lectures, the use platforms that allow to publish educational materials, control students' knowledge in the pedagogical process (for example, MOODLE, Blackboard, etc.);
- fast distribution of knowledge and growth of plagiarism cases (the so-called copy-paste) that demands application of programs to check the uniqueness of texts; access to unlimited educational resources creates for students a temptation to re-rewrite reports and other writings;
- formation of so-called clip thinking in young people and undeveloped skills of reading long texts. Scientists [2, 8–15] speak about the formation of digital (electronic) pedagogy and the transformation of subject-to-subject relations in higher education, the emergence of new education standards, changes in axiological approaches to higher education.

Although there are some limitations: not all universities can adequately respond to the new challenges and provide students and teachers with the tools and resources they need for digital pedagogy. These changes require academic staff not only to be computer literate and able to use modern platforms for disseminating knowledge and

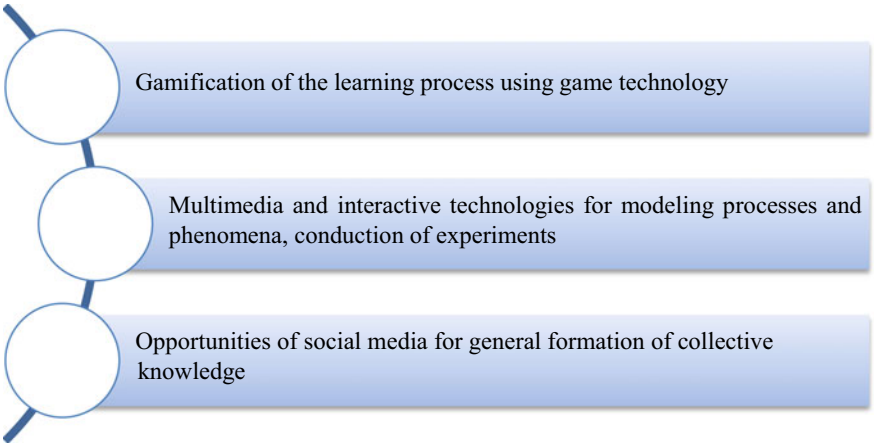

Fig. 1 The most commonly used pedagogical tools in the learning process

their own scientific developments, but also to reflect on the new realities of higher education.

At the current stage of development and global changes in the information society there is an intensive development and use of information in all spheres of society, particularly in education. The process of formation of a digital society with relevant components: smart city, smart army, smart culture, smart education, smart health care is now taking place all over the world. Smart education is the implementation of educational activities on the Internet based on common standards, technologies and relationships established between the network of an educational institution and the team of teachers and students. In the process of smart education, an important role is played by interactive learning technologies, which facilitate interaction between the teacher and students (Fig. 1).

In our opinion, it is now necessary to develop methods for the design and implementation of SMART-complexes of disciplines in the educational process in order to improve the efficiency of learning further. We will SMART-complex to mean an electronic textbook of a new type with features encoded in the SMART abbreviation.

SMART attributes of the educational complex are implemented in the following structure (Fig. 2).

According to the data in Fig. 2, the structure of educational SMART-complexes consists of the following modules:

1. The module for determining the level of training. This module defines the real level of the student (his or her level of training).
2. The module for assessment of learning effectiveness—assesses and records students' learning effectiveness by conducting tests online or in their real world. For the purpose of true testing, students may be asked to find the answer to the control question by observing or interacting with real-world objectives (i.e. real

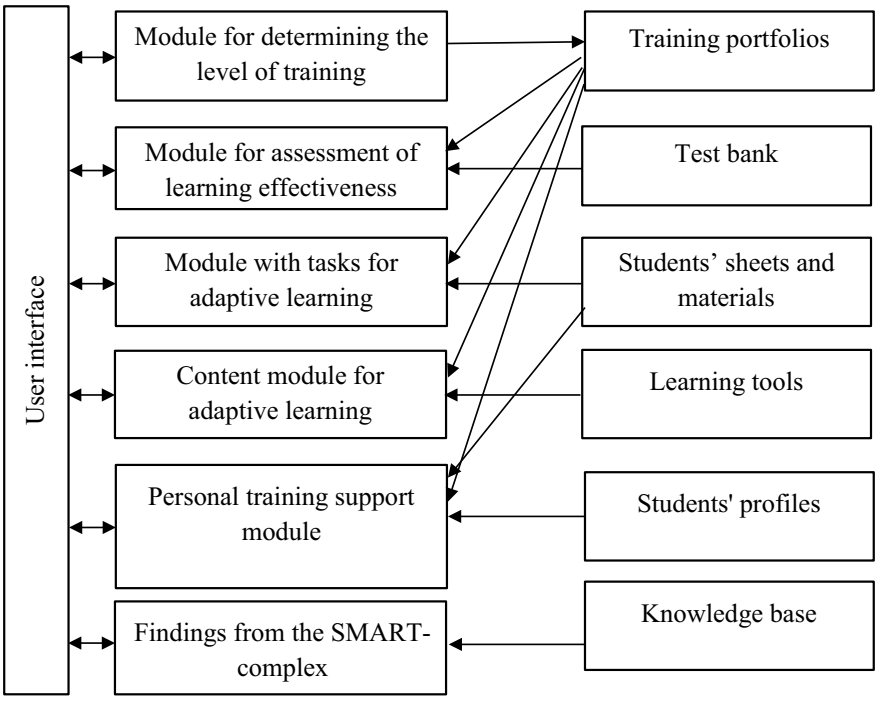

Fig. 2 Structure of the educational SMART-complex

objects related to the learning objectives, e.g.: conditions for the development of cereal plants in a given region, etc.).

3. The module with tasks for adaptive learning. This module assigns tasks to students according to their academic success, performance, personal factors and learning objectives in all disciplines. An assignment can be expressed in the form of an online task—students can be asked to search for information on the Internet or in a real situation; the task can involve observing real objects, searching for additional material from the Internet or in the environment; students can also be asked to give answers to questions. At this, students are involved in the most appropriate and important tasks at the right place and at a convenient time for them, taking into account their learning status and personal factors.
4. The content module for adaptive learning. This module provides learning materials for students. Based on the progress of learning, productivity, personal factors and the status of particular students in the real world, the learning system recommends and organizes the delivery of learning materials, and adapts the interface to meet the needs of particular students. There are now quite a few adaptive (AHA!, MONAP-II, ELM-ART, CALAT, WITS, MLTutor, WebCOBALT, Belvedere, etc.) and intelligent learning systems (Miracle, FLINT, SQL Tutor, ELM ART, etc.). These systems take into account the learner's level of learning and carry out adaptation using different technologies: building a sequence of training courses,

intellectual analysis of solutions, interactive support in problem solving, adaptive hyper-media technologies, etc.

5. Personal training support module. It supports students' learning process based on their learning needs. Learning support can be a reference point for learning purposes or content, a recommendation for a particular assignment and feedback, thus helping students to learn in an effective way. In order to determine what kind of support a student needs, especially in the performance of creative assignments and intellectual tasks, personal factors and the real learning status of students, as well as the effectiveness of their learning should be considered and taken into account.
6. A set of databases for storing learning profiles, portfolios, study letters, training materials, test assignments and information on sustainable learning tools. The data provided in these databases are very relevant to the learning system in terms of providing appropriate support to students (in the right place at the right time). For example, the learning portfolio database stores: students' schedules, their study progress, completed homework, assessment results and the comparative aspect of peer evaluations. Through the analysis of learning portfolio entries, the SMART learning complex offers information to individual students on the feasibility of learning objectives with recommended strategies and tools.
7. A knowledge base with the inference engine for identifying the 'value' of learning objectives, strategies and tools, as well as possible combinations, may also contain rules for decision-making based on case studies of both success and failure. The inference engine is a computer program based on "precedent" technology, which simulates decision-making based on the analysis of the situational state.

In order to formulate and adjust strategies and plans for digital transformation of the educational process, we offer a methodology for assessing the digitalization level of a university based on fuzzy logic.

Assessing the digitalization level of the university will reveal the strengths and weaknesses of the educational process and justify the necessary effective management decisions.

The methodology is based on the analysis and evaluation of the following aspects:

- factors of the digitalization of the university;
- the level of use of information and communication technologies for the digital transformation of the educational process.

Statistical observation of using digital technologies in the educational process with delay responds to new models of using digital technologies, which is insufficient for an adequate assessment of the situation. Therefore, it's necessary to take into account a number of own indicators obtained as a result of expert surveys (Fig. 3).

The following groups of indicators were identified to assess the digitalization level of the university: digital literacy of teachers (A), digital literacy of students (B), digitalization of the educational process (C). In each group, indicators and terms for evaluation are presented, presented in Table 1.

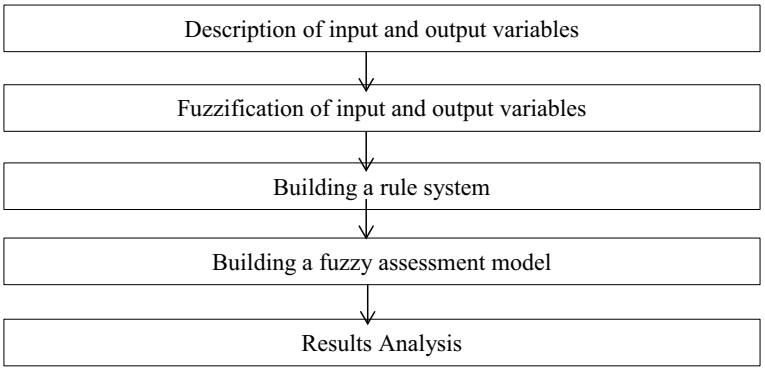

Fig. 3 The stages of the digitalization level of the university based on fuzzy logic

Table 1 Indicators and terms for assessing the digitalization level of a university

Factor code	Name	Universal set	Terms for Evaluation
A1	The use of digital technology in the educational process	1–10 points	Inadequate (in), Low (l), Medium (m), High (h)
A2	The ability to create and share digital resources and materials	1–10 points	Inadequate (in), Low (l), Medium (m), High (h)
A3	Continuing Professional Development Using Digital Technology	1–10 points	Inadequate (in), Sufficient (s)
A4	The ability to develop students' digital literacy	1–10 points	Inadequate (in), Low (l), Medium (m), High (h)
A5	Number of R&D publications	1–10 points	Low (l), below average (ba), medium (m), high (h)
Б1	Providing students with access to digital resources	1–10 points	Inadequate (in), Low (l), Medium (m), High (h)
Б2	The degree of student involvement in active work	1–10 points	Low (l), below average (ba), medium (m), high (h)
C1	The number of online courses in Russian posted on the portal	1–10 points	Low (l), below average (ba), medium (m), high (h)
C2	The number of online courses in a foreign language posted on the portal	1–10 points	Low (l), below average (ba), medium (m), high (h)
C3	Number of computers per student	1–10 points	Inadequate (in), Sufficient (s)
C4	Number of applications in digital services	1–10 points	Inadequate (in), Sufficient (s)

The digitalization level of the university acts as an output variable. To evaluate the initial variable, the following qualitative terms were identified: L—low level indicator, M—medium level, H—high level indicator.

At the next stage, for each value of the term of a linguistic variable, a membership function is constructed.

Decision rules that will indicate a low level of digitalization of the university in terms of fuzzy logic will be determined as follows: «IF the value A1 is insufficient And the value A2 is low And the value A3 is insufficient And the value A4 is low And the value B1 is average And the value C1 is below average And the value C3 insufficient, THEN the level of digitalization of the university is low».

The surface visualization of fuzzy inference is used to analyze the developed fuzzy model for assessing the digitalization level of a university. On this surface, it's possible to establish the dependence of the digitalization level of the university on the input variables. This will reveal the strengths and weaknesses of the educational process, justify the necessary effective management decisions.

4 Conclusion

Thus, reform of higher education should meet the needs of the development of the digital economy, digital society, innovative and creative entrepreneurship and are the main tasks of a competitive country in the context of globalization. We will define the main directions of public policy for digitalization of education, namely:

- creation of educational resources and digital platforms supporting interactive and multimedia content with common access for educational institutions and students, including tools to automate the main processes of educational institutions;
- development and introduction of innovative computer, multimedia and computer-based learning tools and equipment for creating a digital learning environment (multimedia classrooms, training and research laboratory STEM-centres);
- provision of broadband Internet access to students and students in classrooms and auditoriums in educational institutions of all levels;
- development of distance learning using cognitive and multimedia technologies;
- use of SMART-complexes of academic disciplines;
- regular monitoring of the digitalization level of universities.

Thus, to sum up, it is worth noting that digital technologies make the learning process mobile, differentiated and individual. Under such conditions, the priority is to modernize the higher education system in order to provide conditions for the development of digital skills of citizens.

Therefore, in the current conditions, it is necessary to create a comprehensive national system of digital literacy development, combining the efforts of academic and non-formal education on the basis of public-private partnership by developing a list of digital skills and competencies for target audiences of individual industries, development of quality educational content, harmonization of regulatory framework

with European and world scientific initiatives, creation of technical conditions for the use of ICT in education.

In the context of globalization, the introduction of information and communication technologies into educational processes contributes to the individualization of learning, the expansion of access to educational resources and the realization of the possibility of learning without limitations on spatial and temporal characteristics with minimal disengagement from professional duties. However, the socialization of students remains a crucial function of traditional higher education institutions—something that no online or offline courses can adequately provide. International experience shows that in order to improve the quality of education, it is appropriate to use blended learning through different forms of learning.

Influence of Digitalization on Cognitive and Social Orientations of Generation Z

Olga A. Vasilyeva

Abstract Digitalization of the environment, active use of gadgets, the quality of available information content affects the formation of mental processes of young people. Understanding the features of mental and behavioral structures in modern youth is extremely important, since soon it is this generation that will determine the socio-economic development of society. The novelty of the work consists in a systematic presentation of scientific and applied research in the field of changes in cognitive and behavioral structures in relation to generation Z, which is currently the object of close attention of the scientific and business communities. The aim of the work is to study the cognitive and behavioral orientations of generation z representatives. The research methodology consists of applying meta-analysis of secondary data reflecting the results of foreign and domestic research in the field of neurophysiology over the past few years. Additionally, an initial study was conducted using a random sample of representatives of the corresponding target audience, as well as using the "snowball" method. The result of a comprehensive study was the confirmation of the hypothesis of changes in the structure of thought processes and social communication in representatives of generation Z under the influence of digital environment factors. The author offers recommendations for the development of rules of life in the digital space, which will contribute to the preservation of mental and social health of young people.

1 Introduction

Humanity is rapidly plunging into the digital age. Smartphones, gadgets, social networks, digital applications, robotics, artificial intelligence have become the realities of today. Man has changed the environment, made it certainly more comfortable for existence, facilitated many life processes. But human-environment systems are interdependent: transforming the environment, a person changes himself both as a social being and as a biological being. This article will discuss the negative factors of informatization of society that affect the personal development of young people, as well as measures that contribute to maintaining the mental and social health of future generations.

The intensity of the information flow increases every year. Every day, humanity produces and consumes 2.5 quintillion bits of information: over the past two years, 90% of the world's existing data has been created [1]. Indicators increase exponentially. BigData (arrays of structured and unstructured data) occupy information storages of state organizations, transnational corporations, research institutes. It would seem that the possession of big data and free access to any information on the Internet should lead to greater freedom, confidence, reduce anxiety due to lack of information resource. However, numerous studies show that with the increase in the number of available information options (for any request and criteria), the need to make a choice becomes a stressful factor. The statistics are disappointing: the amount of time spent on social networks in 2017 was 135 min per person per day, and in 2019 this figure is already 144 min. At the beginning of 2020, more than 4.5 billion people were using the Internet in the world, which is 7% more than last year. Of these, 3.8 billion "hangs" in social networks. This is almost 60% of the world's population. More than 5.19 billion people use mobile phones, and the number of users has grown by 124 million, or 2.4% over the past year. According to experts, Internet users around the world will spend 1.25 billion years online in 2020, and more than a third of this time will be spent on social networks [2].

At the same time, the consumer of information gets tired of its processing and, as a result, either refuses the information choice or makes it of poor quality. The quality of information content consumed has declined sharply. Prior to the active development of the digital space, in an analogous environment, information material passed through several intermediate test instances responsible for reliability, analytical depth, quality of content and moral standards before being printed and subsequently seen by the consumer. It was required to prove their competence and the right to create information content, having received appropriate education and work experience. Today, the creation and promotion of an information product in the Internet space is accessible to anyone. The roles of producer and consumer of information are mixed. Experts talk about such a phenomenon in the media industry as media convergence. This concept refers to the process of integration of traditional and new media, which is accompanied by duplication of content and/or the creation of alternative media platforms [3]. In this regard, the number of channels for receiving information has increased many times. Separately, it is worth saying that digital

technologies, machine systems and algorithms for processing information content are finely tuned to the interests of the consumer on the Internet. Like, the transition to the thematic link, the comment on the article is immediately processed and captures consumer requests. The next time in a news feed, on a social network, a consumer discovers thematic content that is designed to capture his attention for a long time. Thus, the consumer of information spends the most precious non-renewable resource, often on low-quality content. If an adult is able to control the quantity and quality of information consumed, then digital immersion and dependence trends observed among young people are alarming. A feature of the younger generation is multi-tasking, discreteness of thinking, interactivity, and game realization [4]. It has its own specifics of media consumption and is actively involved in the formation of media reality.

The purpose of this work is to study the transformational processes in the cognitive and behavioral spheres of youth that occur under the influence of digitalization.

The novelty of the work consists in a systematic presentation of scientific and applied research in the area of changes in cognitive and behavioral structures in relation to generation Z, which today is the subject of close attention of the scientific and business communities, since in the near future this generation will determine the socio-economic development of society.

2 Background and Methodology

First of all, a few words should be written about the basic characteristics of the digital generation. In this regard, the our attention is attracted by the theory of generations of N. Hove and W. Strauss, according to which groups of people born in a certain period (the authors of the theory talk about a twenty-year period of time) and developing under the influence of identical socio-economic circumstances form similar value and behavioral orientation [5]. Generations are called baby boomers, X, Y and Z. The young generation, growing up with a “button on the finger”, will in the near future determine the direction of development of all spheres of human life. That it is of most interest to study. The oldest of this generation is already twenty years old. Z is the first generation born in a world where virtually any physical object has a digital equivalent. The real and digital world are naturally connected for them. The virtual world is part of the real world of generation Z. The main features of generation Z include absolute involvement in information flows and processes, a lack of real communication, developed multitasking and, as a result, problems with maintaining attention. It is also worth highlighting the presence of one’s own position, a high degree of personalization, diverse interests and a higher level of enterprise compared to previous generations. There are difficulties in making independent decisions that are related to the peculiarities of education and interaction with the older generation [6].

Some experts believe that the Z generation isn’t a «digital generation» [7]. It’s only an intermediate transitional generation, and the present digital generation will

appear after 2020. However, differences in terminology don't reduce the relevance of studying the phenomenon.

Understanding the characteristics and bringing signals about the mental and social transformation of the young generation will help develop preventive measures to preserve the health of society in the near future [8].

How does the information environment affect the cognitive and behavioral orientations of youth? How does attention, memory and communication structure change? The hypothesis of the study is the assumption that there is a decrease in activity and leveling of the aforementioned personality characteristics under the influence of the digital environment.

In developing the hypothesis, the following research methods were used: a meta-analysis of secondary data, a primary study using random sampling and the use of the snowball method. Desk research was used in the work to collect, process and analyze secondary data obtained from available open foreign and domestic sources. Special attention is paid to the study of neurophysiological studies of the last decade.

Also in this work, the results obtained in the framework of the initial study conducted on the basis of State University of Management are reflected. To obtain quantitative data, a survey of representatives of the youth target audience was conducted. The "snowball" method is popular and seems appropriate for working with the youth target audience, since participation in the survey of friends and acquaintances of the main core of respondents helps to reduce the margin of error for socially expected answers. The research results will be presented below.

3 Discussion and Results

Statistics GlobalWebIndex reports that more than 5.19 billion people use mobile phones in the world. More than 40% of one's waking time is spent on the Internet, with 50.1% of this time actively using smartphones [9]. Confidentiality remains an important issue for Internet users around the world, and recent studies show that today people are even more worried about this than a year earlier. GlobalWebIndex reports that 64% of Internet users are concerned about how companies use their data, compared with 63% at the beginning of 2019. People are less and less trusting what they see and hear on the Internet. 56% of users 18 years of age and older around the world are concerned that it is difficult to distinguish reliable information from fake, compared with 54% last year. 90% of Internet users between the ages of 16 and 64 watch online video every month. This is more than half of the global community. If we talk about the young generation, then on average they spend 60% of their time online. GlobalWebIndex reports that almost half of all Internet users aged 16 to 64 used an ad blocker last month, compared with 47% a year ago. But this is due not so much to the issue of confidentiality as to the abundance of advertising.

Experts in the field of psychology are seriously concerned about the situation, calling the smartphone "a brain expander" and a behavioral machine for controlling human behavior [10]. A dependence on gadgets is formed, they affect the vision of

the world, thinking and health. At the same time, the ability to criticize the consumed information has decreased not so much because of the amount of this information and human laziness, but because of the neurophysiological abilities of humans and the improving algorithms of machine information processing. Studies in recent years in the field of neurophysiology have shown changes in the activity of the formations of the human brain responsible for systemic, critical and analytical types of thinking. Consumed information is reflected in the mental sphere of man. As mentioned above, the process of media convergence has led to the fact that from a generation of "reading", our society quickly turned into a generation of "watching". Most of the information on the Internet is visualized. In accordance with the economic principle of energy conservation, the brain chooses to solve a simpler problem, which is visual or simple textual information content. Media industry representatives compete on how to make information easier. A fundamental transformation of the consumed information has occurred: from the analogous era of the consumption of text and the associated systemic thinking, society has rapidly moved into the era of visual images. Now you can observe the escalation of primitive content. Humanity has fallen into a flurry of "irrelevant, obscure and simply false information fragments", which the Belgian cybernetics F. Heiligen calls "information smog" [11]. Computational power of a person, unlike machine intelligence, is limited by the volume of his attention. When the amount of information exceeds the ability to process it, information overload occurs. In this state, the effectiveness of thinking decreases: a person is more quickly distracted, becomes more irritable and loses the ability to make informed decisions.

The emphasis should be on neurophysiological structural changes in more detail. This is important for understanding the processes of transformation of thinking by modern society in the face of a flurry of visual images on the Internet and primitive information content on social networks. Previously, brain activity was associated exclusively with structural departments: visual, auditory, motor, etc. In the past two decades, experts in the field of neurophysiology have expanded ideas about the functioning systems of the main human organ. Next, the results of some studies will be presented.

An interesting neurophysiological study of a group of scientists at Stanford University under the leadership of M. Raichle, who discovered the so-called default brain system [12].

The human brain operates in three basic modes:

1. Active mode. This is a state of concentration and retention. In this mode, incoming information is intensively consumed. The central performing neural network is responsible for these cognitive processes.
2. Orientation mode. In this state, spatial orientation and processing of information related to security and adaptation to surrounding signals takes place. The neural network of revealing significance controls these processes, which, if necessary, triggers the "fight-run-freeze" behavioral response.
3. And finally, the recently opened "default system" (default mode network). The mode of operation of the brain, which is in a passive state. This state, when a

person is immersed in himself, does not solve a specific problem, as if disconnected from reality. However, as it turned out, this is the most important mode of the human brain. It is he who connects the structural aspects and forms systemic thinking. It is in this state that discoveries, the so-called "cognitive insights," take place. At rest, the brain spends about 46% of conscious time. It is also proved that this particular brain mode is evolutionarily the most socially oriented. The default system in a state of "thinking about nothing" analyzes situations with people around us: relationships, expectations, conflicts. It is designed to solve social problems.

The default system requires some time for its activation, namely, twenty-three minutes is required for it to start. Moreover, on average every fifteen minutes, a person's attention is interrupted by external factors (calls, social networks, mobile applications). A modern person, especially among young people, does not have enough time to load informational images into the default system.

Developing the concept of brain operating modes, a group of American scientists from Stanford, led by Professor Ashley Chen, conducted a study of the mechanisms of turning on and off neural systems [13]. It turned out that the above-described brain modes are antagonists. That is, when the orientation and conscious information processing modes are active, the default system is in a passive state. As indicated above, it takes twenty-three minutes to start a default system. That is, with the constant consumption of information from the Internet, social networks and gadgets, the mode of the brain responsible for thinking does not work. Neural networks do not form; analytical work abilities do not develop. Hence, in modern society one can increasingly hear about the "clip" type of thinking, that is, thinking with stereotypes in the absence of the ability to build causal relationships. Surprising was the fact that the formation of neural networks that form three modes of the brain takes twenty-five years of life. That is, a child—a teenager—an adult does not just study the world around him, but forms his own software server, which in the future in adult life will be responsible for the ability to think.

In this vein, we can recall an experiment conducted in 2017 by specialists from the University of Texas at Austin (USA). Researchers have proven that the location of a smartphone affects cognitive abilities. An experiment was conducted in which students were divided into three groups and asked one group to leave the smartphone outside the room, the second group to put the smartphone in a pocket or bag, and the third group was recommended to be left nearby, but turned with the screen down. Moreover, all three groups performed intelligent tests. During the experiment, it turned out that the physical location of the phone affects the amount of RAM and mobile intelligence. The second and third groups showed significantly worse results than the first. Part of the cognitive resource is drawn to subconsciously waiting for the phone signal, even if it is in silent mode [14]. In another part of the experiment, some students were allowed to talk on a cell phone. During the conversation, a clown dressed in a bright suit walked in visible accessibility. Surprisingly, the majority of those who spoke at that moment on the phone did not notice the presence of such a bright character. Then they were extremely discouraged.

In the fall of 2019, on the basis of State University of Management, a study was conducted on the characteristics of communication of modern youth. The study involved 182 respondents aged 18 to 24 years. 100% of respondents use social networks for communication, of which the most popular are VKontakte (97.8%), Instagram (80.2%), Facebook (10.4%), instant messengers—WhatsApp (76.9%) Telegram (60, 4%) and Viber (23.1%). Communication takes place with close friends, relatives and acquaintances. Time spent on social networks per day: more than 5 h (45%), 2–4 h (39%), less than 2 h (16%). At the same time, the maximum abstinence from checking social networks is less than an hour for 45% of respondents, up to 4 h (23%), up to 1 day (32%). Popular types of content on the network are news (36%), beautiful life (31%), challenges and humor (27%). It should be noted separately that respondents do not directly participate in the challenges (only 17% had similar experience). 84% of respondents recognize the dependence on social networks, while this fact does not cause concern—81% of respondents do not see a problem in this dependence. Personal communication for respondents was slightly preferable—58% of the survey participants like offline communication, 42% prefer online communication. To the question "What are decisive factors for you when choosing a certain type of communication?" The following answers were received—the ability to hear the voice and intonation of the interlocutor (50%), the speed of message transmission (52%), the ability to observe facial expressions and gestures (39%), the ability to communicate at a distance (80%), cost (17%). The choice in favor of voice or video communication is carried out by 100% of respondents when they are interested in transmitting a large amount of information and receiving quick verbal or non-verbal feedback. 80% of the survey participants subscribed to bloggers on social networks. At the same time, the majority recognizes the full-format video (41%), textual information with photo illustrations (22%), short video (20%), live broadcasts (14%) as the preferred communication format between the blogger and the audience. As expected, the text format has a low indicator—only 3% of respondents prefer it. The rate of negative experience on the Internet is high—75% of respondents have experienced bullying attempts on the network, while the majority ignored these attempts (58%), the rest coped with the help of loved ones or on their own (17%). The style of communication in a social network directly depends on the interlocutor, as in personal interaction. This status, duration of acquaintance, age, behavior, degree of interest. To the question "Is it necessary to regulate communication on the Internet (both at the legislative level and at the level of establishing rules by social network administrations)?" slightly more than half of the respondents (52%) answered negatively, some recognize the need for moderation (11%). There are likely socially expected answers, but this study does not contradict secondary analytics.

The human community recognizes that mobile phones, tablets, computers completely absorb attention. There are also alarming signals demonstrating the need to take control of interaction with gadgets. Studies show that young people from 18 to 24 look at their smartphone 86 times a day. If you spend more than 2–2.5 h on the phone without a break, then the rates of depressive thoughts and suicidal tendencies increase significantly. Characteristics such as social tension, aggression, alienation, conformity also become more pronounced in the behavior of the individual. Not to

mention academic performance. An average student 3–5 times per lesson checks his mobile phone and this affects academic performance [15]. The phenomenon of distal vision is also manifested—the inability to think about the future, set goals, and plan. These abilities have always distinguished a person as a biosocial creature and in many ways determined his superiority in the animal kingdom. Norwegian experts at the Center for Economic Research Ragnar Frisch published research results in the journal Proceedings of the National Academy of Sciences, which claimed a steady decline in human intelligence over the past decades [16]. A relatively safe environment and a stable existence have reduced the need for ingenuity and adaptive functions.

The term "information pseudo-debility" has recently appeared [17]. It means a mental state in which a person is not able to collect complex intellectual objects. This activity requires a developed neural network, and as already mentioned, the modern digital environment does not favor the development of neural connections. The passive state of the default system affects mental activity, which is especially alarming in the childhood-teenage period of the formation of mental systems. The general attitude towards hedonism in the absence of the ability to plan for the future leads to the fact that representatives of the Z generation are not tolerant of their failures and expect easy success. Once again, we outline the main causes of this phenomenon:

- Information dependence: a modern person 24/7 consumes information with a tendency to consume simple content that does not load the brain.
- Accessible and relatively safe environment: there is no need to adapt and create, motivation awakens.
- Information intoxication: an overabundance of incoming signals leads to protective reactions, information is perceived as "noise".

Also a consequence of the influence of the digital world is the transformation of the structure of social interaction. Generation Z faces difficulties or inability to maintain long-term social contact. Young people have little interest in the inner world of another person, do not see the value in a separate person. Social learning skills are lost, personality traits such as empathy, ability to interact, and emotional intelligence are not formed. At the same time, the orientation toward building long-term relationships decreased. It is thought that in the near future, society will observe a pronounced transformation of the institution of marriage.

4 Recommendations and Conclusions

Generation Z was born and lives in the era of digital reality. Transformation of behavioral and cognitive abilities is inevitable. The environment affects the person, as well as the person affects the environment. A change in the consumption of information divides the world into "smart" and "stupid" in the truest sense of the word. A gradual atrophy of mental skills occurs. Humanity transfers this function to

artificial intelligence. It is difficult to say what the "brain unloading" will turn out for future generations. However, it is obvious that there is a division of the community into those who use digital products and those who use these products. Of course, one cannot speak only about the negative aspects of the influence of the digital era on man. The description of such large-scale processes in polar uncompromising black and white tones seems limited. Digitalization, as a phenomenon, avalanche-like captures all spheres of human activity. And since it takes root in the environment, there are much more positive results of its influence than negative ones. A lot of scientific and practical work has already been written about the positive impact of digitalization. The objective of this work was to pay attention to the reverse side, to negative changes in the thinking of an almost digital person and to make a number of proposals to reduce this impact.

The key recommendation comes down to the need for conscious consumption of digital media products. If the questions are "Why?", "What result do I need?", "How does it promote me?" begin to regularly arise in the minds of young people and gradually become a habit, the user will gradually improve the quality and quantity of information content consumed. In particular, it makes sense to understand the basic mechanisms of the operation of social network algorithms in order to begin to control the degree of dependence on them [18]. Initially, social networks were created on the principle of retaining user attention. The developers took into account the basic psychological and biological mechanisms of thinking and human behavior. For example, when receiving social approval (like, positive comment), the dopamine pleasure hormone production system is activated in the human brain. Machine algorithms are programmed in such a way that they track the topic of the user's information content and select information to which an unconscious and instant reaction is formed. This creates endless catchy information content. To begin to get rid of the "soft" power of algorithms, you should monitor your reactions and ask the right questions. An analysis of the benefits obtained helps: the ratio between the amount of spent resources (attention, time, etc.) and the benefits received. The questions "What next?", "What is the purpose behind the goal?" Help. The habit of questioning incoming information helps train critical thinking and develop a personal position. This practice increases awareness and the brain activates the necessary for planning, decision making, formation behavior control. Neural connections in these brain zones are gradually strengthened and a habit is formed to distinguish garbage content and control involuntary desires to consume it. There are forces and a desire to fill the information stream with quality content.

The following recommendation comes down to digital hygiene. As the childhood health monitoring habits are formed, it is also necessary to instill the rules of digital hygiene [19]. This is a "cleaning" of their smartphones, social networks, email and other gadgets. Like the general cleaning of the apartment or the revision of the wardrobe, attention should be paid to cleaning the digital assistants. The key word here is "delete". Removing unnecessary information, unnecessary contacts, updating passwords helps to get rid of "information noise". You need to unsubscribe from publications that duplicate each other's news and thematic agendas, as well as remove resources that are supported due to friendships from your feed. How to understand

what is superfluous and what is not? If there is no appeal to information, contacts, publications, blogs within six months, then you can safely delete or transfer to the archive section. Another rule of digital hygiene: like distributing things in a closet on shelves, in the information space you need to use different services for different purposes.

The third recommendation relates to social contacts. It is important to honestly answer yourself the question "Who steals my time?", "What format of interaction with a specific person will be most effective?", "How important is the information coming from a specific person?". Social interaction develops thinking, forms behavioral patterns, affects the level of psychological well-being. You should choose interesting people from whom you can learn something. If high-quality communication is not supported, and the costs of maintaining a contact exceed the benefits received, it is better to get rid of it or transfer this contact to the archive. The number of contacts certainly affects the quality of communication with them. It's better to narrow your circle of communication and make efforts to build trust and long-term relationships. The remaining contacts are classified according to the degree of importance and formalize the interaction. This work is related to the ability to manage relationships. Rare personal meetings with real, not virtual people will bring much more benefits.

The final recommendation comes down to the concept of digital silence. This time spent without gadgets. As mentioned above, the default system of the brain, which is responsible for systemic thinking, takes about half an hour to activate the work. Three to four hours a day or twice two hours a day is proposed to be carried out without smartphones, telephones, computers and other information assistants. This time should be devoted to yourself: reading smart books, sports, meditation, walking, silence. Nowadays, this recommendation may seem the most difficult to implement, but it is directly related to mental health and psychological well-being [20]. Adult generations should show and gently guide young people toward healthy living in the digital world.

In conclusion, it should be noted that the issue of changing the thinking and behavior of a person under the influence of factors of the information environment, it is necessary to pay close attention to prevent social degradation. Further study of the topic involves the involvement and interconnected work of the scientific, business and cultural communities. Testing of recommendations and determination of their practical significance is required. However, following the suggested tips on the formation of new life habits in the digital space, we can assume the preservation of the mental and social health of the digital consumer of the Z generation information.

Empathy and Identification as an Online Technology of Blogger's Communication in Digital Marketing

Galina V. Dovzhik, Valeriy N. Dovzhik, and Olga V. Kurasova

Abstract This article is about innovative technology of digital marketing, which allows communicating successfully with producers of goods with consumers at the stage of making a purchasing decision in order to increase sales of goods and services. The specifics of the purchasing decision-making process in the online environment at all its stages are described, the theoretical justification for the inclusion in the digital purchasing decision-making process of a blogger purposefully using the socio-psychological mechanisms of empathy and identification, is described. The result of it is an additional stimulating effect on the consumer when he became acquainted with a particular product. The results of the author's empirical study proving the effect of these mechanisms in the process of making a purchasing decision are presented. It's described that, provided to the subject to the actualization of the buyer's conscious needs, the blogger creates the unconscious needs of the recipients that affect the consumer's interest in the product, and, as a result, the level of willingness to purchase goods increases. At the same time, the corresponding emotion of the blogger is transmitted to the potential consumer, which leads to an increase in the likelihood of buying a product. The scientific novelty of this technology lies in the fact that for the first time it has been theoretically described and practically proved the feasibility of using socio-psychological mechanisms at certain stages of the decision to purchase in digital marketing. It's empirically proven for the first time that the targeted use by a blogger, a reference person, of the totality of the socio-psychological mechanisms of empathy and identification at the time of contact with a potential buyer increases the buyer's willingness to purchase the appropriate product. This is the substantial essence of this online digital marketing technology,

1 Introduction

In the era of global digitalization of all economic sectors, the issue of successful online communication between manufacturers and consumers has become particularly important, since the effectiveness of direct marketing declines and the market dictates the need to develop innovative technologies that will help boost sales via online communications. One of the most future-oriented online technologies that will make the online communication with the customer more efficient, and thus raise sales, is communication with representatives of the target audience through a blogger as a symbolic intermediary between manufacturers and consumers who intentionally uses a combination of social and psychological techniques such as empathy and identification in making a purchase decision.

Digital marketing pays special attention to purchase decision-making. Blackwell R. D., Angel D., Miniard P., Bykova M. K. and Azoev G. L. theoretically developed and gave science-based underpinning of purchase decision-making. And nowadays, bloggers have a major impact on the success of the purchase decision-making. For instance, according to a study conducted by Admitad analysts, the amount of online sales through bloggers and "opinion leaders" for the first half of 2019 made up 60 billion, and specifically for this period increased by 21% in social networks. Besides, over half of purchases were made via social network VKontakte, where sales soared by 53% [1]. It is this fact that justifies the choice of a communication channel with the target audience when the authors conducted an empirical study.

Let us describe the purchase decision-making on the Internet with the participation of the blogger as a symbolic intermediary between the manufacturer of the goods and the customer. Thus, at the first stage of decision-making, the consumer recognizes the need for something under the impact of need-activating factors that give impetus to its occurrence [2]. Usually, these factors are age, sex, and situation. Next, the consumer starts searching for information necessary for making a decision about a product or service. There are two types of searches (internal and external). The internal search involves an analysis of previous experience and knowledge about the

product, ease of use, quality and feelings after use. An external search consists in the assessment of the information available in the mass media, to which a blogger with a vast number of subscribers belong to, as well as advice and recommendations from friends and acquaintances, including social networks and messengers. As a rule, the consumer uses external search if he does not have sufficient personal experience (the need arose for the first time) or wants to try something new. The third step in the purchase decision-making is the evaluation and choice of options before the purchase. At this stage, a wide range of goods, the availability of full information about them on the website or in the blog, the frequency of purchase (spontaneous or regular), and individual selection criteria of the consumer are critical. This stage is followed by online purchase, therefore the secure and convenient payment, as well as home delivery or feedback option, are essential. Then goes the stage of consumption, where the main factors are ease of use, storage and lack of side effects.

At this stage, during the utilization of goods the consumer can get a positive experience, negative experience or dissatisfaction. A positive experience is getting positive feelings from the purchase due to product properties such as high efficiency, good quality, ease of use, etc.

Dissatisfaction is getting negative experience of consumption resulting in the avoidance of purchases (side effects, poor quality of the product or its low performance, complicated use, etc.) Negative experience is trying not to find out in the state of dissatisfaction through which the person also gains positive experience from the purchase. The final stage of the purchase decision-making is the evaluation of the product's use by the consumer. If the evaluation is satisfactory, then the process is cyclical at the fourth stage (the purchase), i.e. factors such as problem awareness, information search, and evaluation of options before the purchase are skipped. If the evaluation is unsatisfactory, then the purchase decision-making will restart from the first stage in the event of sufficient the number of need-activating factors [3].

Thus, the blogger enters into online communication with a potential consumer through publication of video, audio and photo content at the second, third and fourth stages of the purchase decision-making. However, the social phenomenon of blogging is not yet scientifically based.

Despite that blogging has been explored since the end of the nineteenth century and various types of communication efficiency in the blogosphere, as well as their criteria, have already been identified, this topic is challenging. The progressive development of modern technologies evokes the emergence of new channels and types of communication between bloggers and subscribers, and, consequently, new technologies for online interaction.

Although the blog dates back to the first half of the 90s, initially it was textual, like an online diary. The main difference of blogs from the traditional diary was focus on a wide audience and publication in a social network. Blogs of that period are characterized by low interactivity, as they allowed communicate with the audience only through text comments. Initially, the term "blog" meant "a website where someone writes about their beliefs, activities, and experiences" [4]. But technologies for communication with consumers of goods have drastically changed, and only textual content has turned out to be not enough for productive interaction. Therefore,

since 2011, bloggers have started to add video content, which made mainstream platforms like LiveJournal, Blogger, etc. unpopular. From that time, blogs have become much different from the first text versions and allowed a blogger to communicate with the audience not only via text messages but also through photo, audio, and video content. The above transformations raised the popularity of blogs and allowed bloggers to benefit from them by advertising [5].

Today blogging is a large-scale phenomenon that embraces almost all areas of people's lives, which makes it an exclusive tool for online sales and an integral part of digital marketing, influencer marketing. Modern bloggers are treated as mass media. They are opinion leaders for their subscribers who earn millions through advertising. According to Forbes magazine, the most successful Russian bloggers in 2019 were Kseniya Sobchak, Nastya Ivleeva and Yuriy Dud' with 1, 0.9 and 1.4 million dollars respectively [6].

One of the essential criteria for bloggers' performance is the amount of sales made by their recommendation. In addition to sales criteria, there are usually the number of subscribers, view reach and the number of targeted clicks [7]. For high sales figures, the blogger should build communication in a way that he/she could persuade the consumer to make a decision on the purchase of a product or service (the fifth stage of the purchase decision-making). If the content published by the blogger meets the interests of the potential consumer, then in this situation it can be referred to the need-activating factors. Further, at the stages of information search and evaluation of options before the purchase, the completeness of information on the product provided by the blogger, as well as the blogger's reference rate and a common emotional space between the blogger and the potential buyer is in priority. Therefore, we deem it expedient to describe the action of a qualitatively new technology of online communication between a blogger and a subscriber based on a combination of socio-psychological mechanisms of empathy and identification. Besides, it should be noted that the performance of this technology is contingent on the blogger's reference for subscribers. In our understanding, the blogger's reference is a high consistency (almost complete identification) between the interests, opinions, and values of the blogger and the target audience; some kind of quality of the subscriber existing in his mind and reflecting the level of identification of his own judgments, rules, values and opinions with attitudes, opinions, and estimates of the blogger. That is, the higher the consistency of opinions, the higher the reference of the influencer and user of the content. Thus, we figuratively treat a blogger-reference person as a check-point for a subscriber-customer when developing a model of his behavior in making a purchase decision.

In addition, the socio-psychological mechanism for identification of the user with the influencer comes into action only if the blogger is a reference person in communication with the subscriber-customer since the subscription allows talking about the consistency of opinions, estimates, judgments, attitudes, behavior patterns of the user of the social network and the person he subscribed. G. Feltser supposes it's the essence of the identification mechanism [8]. The subscriber thinks something like this: a person with whom I agree and completely trust, bought the product I need, which means I will buy exactly the same product without an additional check.

That is, identification is one of the vital socio-psychological mechanisms, and on the Internet too. During online communication, one person (subscriber) subconsciously assimilates himself with another (blogger). As A. Freud described, the subject of identification unconsciously identifies oneself with an object [9], namely the subscriber with the influencer. Thus, thanks to the socio-psychological mechanism of online identification, a subject possesses the desired object in symbolic terms and keeps the emotions.

Next, let's address the effect of the empathy mechanism. Empathy is understood as comprehension of an emotional state, penetration into feelings of the person [10]. Therefore, in this article under the term "empathize" we mean a person's ability to perceive emotional states, i.e. show empathy. E. A. Ichalovskaya in her work says that the initial form of empathy development is emotional invasion, which then turns into emotional identification, that is, treating the feelings of the empathy object as your own [11]. Then the subscriber perceives private open variables of the empathy object (blogger) such as emoji, stickers, gif-animations, memes, emoticons, punctuation, way and style of communication.

The third stage is the interpretation of external variables such as the time factor, the task factor, the individual features of the communicator and the recipient [12]. The communicator here should be a blogger (reference person), and recipients—representatives of his target audience (subscribers).

To assess the action of the socio-psychological mechanisms of empathy and identification, we conducted an empirical study.

2 Background and Methodology

In order to determine the effect of the socio-psychological mechanisms of empathy and identification, we conducted an empirical study.

The theoretical and methodological basis for this empirical study was the work of R. D. Blackwell, D. Angel, Miniard P., Bykova M. K., Azoeva G. L., Dovzhika V. N., Kurasova O. V., Ichalovskaya E. A.

The purpose of the study is to prove that a combination of empathy and identification mechanisms is a useful digital marketing technology for online communication between bloggers and customers in digital marketing in the process of making a purchasing decision, which allows increasing sales.

At the same time, we assume that the use of a set of socio-psychological mechanisms of empathy and identification in a digital environment by a blogger as a reference person who purposefully uses these mechanisms at the time of contact with a potential buyer increases his willingness to purchase the appropriate product.

The theoretical methods (analysis, generalization, and synthesis) are aimed at solving the problem of the study.

In the course of the study, we have employed the methods of collecting primary empirical information such as a critical analysis of academic literature, a secondary analysis of documents, questionnaires, and an online survey.

In the questionnaire, we included a list of the most successful Russian bloggers for 2019 according to the rating of Forbes magazine: Yuri Dud, Nastya Ivleeva, Ksenia Sobchak and others [6].

For the analysis of primary empirical information, we have used the methods of generalization, comparison, logical and correlation analysis.

Statistical processing of data attained during the study has been made using SPSS 17.0 program for Windows.

The scientific novelty of this technology lies in the fact that for the first time the possibilities of using socio-psychological mechanisms at certain stages of the decision to purchase in digital marketing are described. This online digital marketing technology makes it possible to increase sales in the long term by influencing the consumer of a reference personality acting as a symbolic intermediary between producers of goods and representatives of the target audience in the process of making a purchasing decision. The results of the author's empirical study proving the effect of these mechanisms in the process of making a purchasing decision are presented.

For the first time it is described that, subject to the actualization of the buyer's conscious needs, the blogger creates the unconscious needs of the recipients that affect the consumer's interest in the product, and as a result, the level of willingness to purchase goods increases. At the same time, the corresponding emotion of the blogger (for example, the joy of "What a cool product") is transmitted to the potential consumer and the same emotions appear in his mind at that moment in time (transfer of emotion from the blogger to the recipient), and then the identification mechanism is activated at the next level (identification) with the influencer ("I also want to own such a cool product!"), which serves as a serious incentive to fulfill the need that has arisen, and leads to an increase in the likelihood of buying a product.

The practical significance of the results of the empirical study lies in the fact that the conclusions and suggestions contained therein are aimed directly at improving the effectiveness of online digital marketing technologies and can be used in the practical activities of digital marketing specialists and bloggers to increaseт their sales.

3 Results

At the first stage of the study, for identification of factors affecting the empathy of one person to another, we developed a special methodology and surveyed representatives of the target audience with 216 Internet users of 16–35 years old. The sample is random since any network user can participate in an online survey.

After analysis of the findings of the empirical study, we revealed that the main factors affecting the communication are "availability of free time" (72.2% of respondents), "individual features of the communicator" (67.6%) and "focus on activities" (27.3%) (see Fig. 1). Bearing in mind the above figures we can conclude that consistency between the individual features of the respondent and the communicator is an integral part of online communication because it means the creation of common

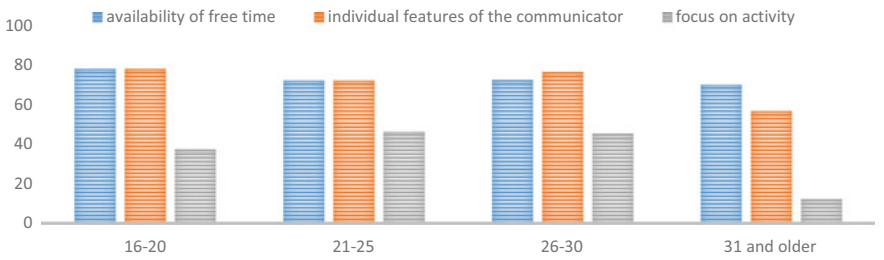

Fig. 1 Factors affecting the empathy mechanism in the communication

emotional space between the parties, and, therefore lay the groundwork for the empathy mechanism.

It is interesting that there is a strong statistically significant relationship (0.1) between the variables "age" and "focus on activity" (Pearson correlation 0.269). Only 37.5% of respondents of 16–20 years old have chosen the factor "focus on activity" as the main one. But as for the 21–25 age group, this factor was picked by 46.5% of respondents, among 26–30 age group—by 31% of respondents, and over 31 years old—by 12%. It is not surprising, because people of over 31 years old belong to generation X, and 16–30-year-old respondents—generation Y. According to the theory of generations, Y is the generation of social networks.

Since the surrounding has changed rather quickly, they are full of energy, easy-adaptable, can perform a vast amount of work in a short time, and, therefore, have a stronger focus on current activities [13].

There is a statistically significant relationship (0.1) (Pearson correlation −0.253) between the variables "free time" and "individual features of the communicators", which indicates that if the respondent chooses "availability of free time, he will not deem important the "individual features of the communicators" and vice versa.

All the above said leads to the conclusion that empathy mechanism cannot be used in online communication without "availability of free time", consistency between "individual features" and "focus on activities" (for over 20-year-old people). These factors lay conditions for common emotional space and after that people can pass to the stages of empathy.

In the second stage of our empirical research, we put the task to show the action of the socio-psychological mechanisms of empathy and identification. We also developed a questionnaire with regard to the specifics of the task.

A sample of the study are consumers of 18–34 years old, actively using digital marketing technologies and having an account on social networks. The total sample size made up 205 respondents.

To prove the action of the socio-psychological mechanism of empathy, we explored the key stages such as joining the object of empathy and decentration of the subject of empathy when the object is a blogger. At these stages, there is a common emotional space of the blogger with representatives of the target audience, i.e. the

blogger's feelings and emotions are shared by the audience. And this situation gives rise to an emotional relationship between the blogger and the audience.

According to the findings of the second stage, the most popular social networks and video hosting sites today by the criterion of use are Vk (Vkontakte), Instagram, YouTube (99, 93.7, and 93.2% respectively). Next, follow TikTok and Facebook (29.3 and 22.4% of respondents). However, accounts in Vk (Vkontakte), Instagram, YouTube are kept by 98.5, 93.7, and 83.2% of respondents respectively. Along with that, 43.9 and 26.3% of respondents have TikTok and Facebook. In total, 89.3% of respondents subscribed to bloggers on social networks and video hosting sites.

The most interesting blog topics for respondents are travel (63.9%), beauty (51.2%), fashion (47.8%). The least popular topic is children (13.7%) due to the young age of the respondents.

According to the results attained in the online survey, Yuri Dud' is the most popular blogger. He is well-known to 92.2% of respondents. Nastya Ivleeva and Ksenia Sobchak hold the second and third places (91.7 and 84.9% respectively). The least popular blogger is Wylsacom (Valentin Petukhov). Only 51.1% of respondents know him (see Fig. 2).

The blogger should have the features to make a respondent subscribe to his account, such as interesting content, awareness of the topic, close emotional relations, as well as common interests and values. The answer "interesting content" has been chosen as a key condition for need activation in making a purchase decision. Through activation of conscious needs, the blogger evokes the unconscious needs of the recipients and respectively the interest in purchase. In a perfect scenario, this interest should be satisfied with the help of the information provided by the blogger in the decision-making on the purchase of goods. The emotion of the individual arising at the moment signals that the actions taken for satisfaction of the need correspond to the need itself.

The second popular answer is "awareness of the topic" (72%). One of the important blogger's features in the identification is competence, expertise and no intention to manipulate the audience (reliability). In identification, the individual accepts influence as a means of consolidation of his inner values.

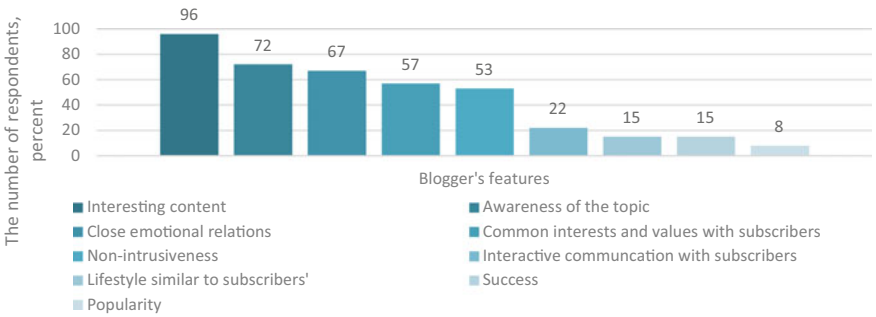

Fig. 2 The blogger's features essential for subscription

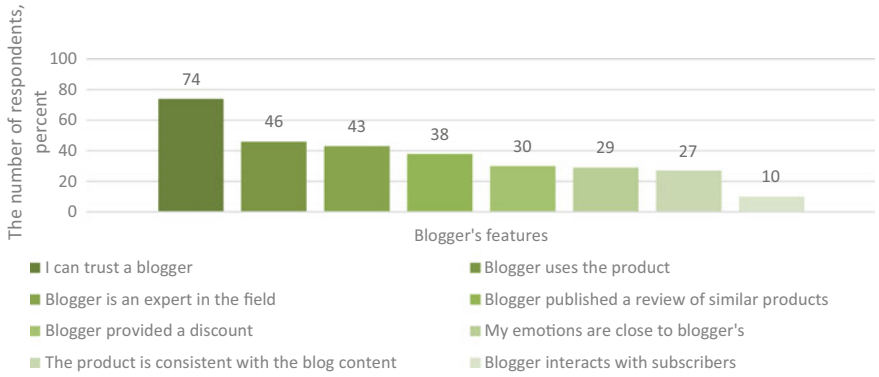

Fig. 3 Incentives for the purchase of goods by blogger's recommendation

It makes sense that reliability, which is one of the trust indicators, is the most meaningful in a purchase situation since for respondent it's more responsible action than subscription due to time and financial expenses.

The second answer is "close emotional relations" (67% of respondents). This answer means that the emotions of the blogger are close and transparent to his subscribers, i.e. we can talk about empathy and a common emotional space between the blogger and the subscriber.

The answer "success of a blogger" is the least popular (8% of respondents) due to the age of respondents (generation Z) [13]. Under generation theory, representatives of generation Z do not think that success is an important feature of both the blogger and the individual (see Fig. 3).

The interesting fact is that 65.4% of respondents buy products advertised by bloggers.

According to the research findings, the main incentives for purchase by blogger's recommendation are trust, blogger's experience as a user of the product and boggers' awareness. The "trust" has been chosen by 74% of respondents, which makes it a key condition for the purchase of a product or service, as far as trust is a cumulative component of the blogger's reference [14].

The next popular answers chosen by half of the respondents are "blogger is an expert and "blogger uses the product". This fact is the result of a socio-psychological identification mechanism. The idea of the latter is that respondents identify themselves with the blogger-reference person and simulate his behavior model.

4 Conclusions

Therefore, our assumption that the use of a set of socio-psychological mechanisms of empathy and identification in a digital environment by a blogger as a reference person who purposefully uses these mechanisms at the time of contact with a potential buyer increases his willingness to purchase the appropriate product is correct.

In the process of empirical research revealed at the first stage:

- As a result of the correlation analysis, a statistically significant relationship was found between the variables "age" and "focus on activity". Thus, this allows us to conclude that in order to create the conditions for using the empathy mechanism in online communication, the presence of factors is necessary: "availability of free time", coincidence of "individual characteristics" and, for the age category over 20 years, "focus on activities", While creating the prerequisites for creature a common emotional space.

At the second stage:

- it was empirically proved that the main characteristics, which are necessary for a blogger to subscribe to him, are: interesting content, awareness of the topic, emotional closeness and also common interests and values with the blogger;
- it was revealed that the main incentives for buying a product from a blogger are: trust in the blogger, personal use of the product by the blogger and knowledge in this area;
- in the process of making a purchasing decision, the identification of a blogger—a reference person with a target audience - is an effective online digital marketing technology and leads to an increase in sales;
- in the process of making a purchase decision, the empathy of a blogger with a target audience is an effective online digital marketing technology and it leads to an increase in sales;
- a set of identification and empathy mechanisms gives a cumulative effect in the online communication of a blogger—a reference person as an intermediary between a producer of goods and a buyer in digital marketing in the process of making a purchasing decision, which in turn leads to an increase in sales.

One of the most significant conclusions obtained as a result of the study can be considered that effective blogging online communication consists of two stages.

At the first stage, the empathy mechanism has the greatest weight, provided that the needs are actualized, so that the user performs the target action—subscribes to the blogger. Further, to complete the purchase of goods, the socio-psychological identification mechanism through which the subscriber copies the behavior model of the blogger-reference person acquires the greatest importance.

Quality of Higher Education: Key Components of Stakeholders' Assessment

Ekaterina A. Kameneva, Liliya V. Prikhodko, Natalia V. Sergeeva, and Aleksandr G. Tyurikov

Abstract The article describes the findings of the research into the Russian and international practices of building the higher education quality assessment system. The issue of building of national higher education quality assessment system based on the modern challenges faced by the contemporary higher education system and the best international practices gained in external and internal quality assessment system development are examined. The article is part of the commissioned research conducted by the Financial University in accordance with the order of the Government in 2018.

Keywords Higher education · Higher education quality assessment system · International quality assessment agencies · Occupational standards

1 Introduction

Higher education systems play an important role in the development of any society and economy. The goal of the Global Education 2030 Agenda developed by the UNESCO is to build a knowledge economy that will ensure sustainable employment and high living standards. It stresses the importance of reliable quality assessment and quality assurance systems.

Today, the higher education quality assessment and quality assurance systems development gains momentum worldwide. The key drivers of this are the increasing public demand for high-quality educational services, a solid stakeholders' demand for the education system efficiency improvement, the need of highly-qualified personnel who could manage national economies and the need of better using the public resources for the education system development purposes.

Quality control and quality management are the priorities in the Russian education system modernization process. The current understanding of the Russian national education quality assessment system is based on combination of institutions that ensure use of a single methodology and concept-based assessment of academic achievements and identification of personal children's and adults' qualities and factors that make an impact upon the learning outcomes.

The internationalization and globalization of higher education requires the harmonization of quality assessment and quality assurance systems. The comparative analysis of the Russian and international practice of higher education assessment systems underlines the possible ways for contingence of different approaches that should have a positive impact on the development of global learning environment.

2 Methodology

Authors conducted a survey of conference participants to identify the key components of higher education quality during the annual Education Foresight: Accreditation Bounds VS Academic Freedom International Financial University Research Conference that was held on 20–22 March 2019. The survey respondents were the 1300 representatives of the academic and industry community and 580 students from Moscow, St. Petersburg, Sevastopol, the Republic of Bashkortostan, the Republic of Dagestan, Altai Territory, Nenets Autonomous Area, Krasnodar Territory, Moscow, Omsk, Oryol, Penza, Chelyabinsk, Yaroslavl, Vladimir, Saratov, Novgorod, Tula, Lipetsk, and Novosibirsk Regions.

When answering the question "What is the most objective procedure to be used to assess and recognize higher education quality", the respondents identified the key indicator of education quality was the graduate employability. According to them, the accreditation performed by the government accreditation agencies is as important as that performed by the independent accreditation agencies and the rankings have virtually no significance as far as higher education quality is concerned (Table 1).

The higher education quality assessment system in the Russian Federation includes the following: assessment by the government institutions made through the use of the state accreditation procedures, education system monitoring procedures and assessment performed by the independent stakeholders via industry accreditation, accreditation by accreditation agencies, international comparative analysis and other education quality assessment and monitoring procedures (Fig. 1).

Operations in the field of education in the Russian Federation are regulated by the federal state educational standards (except for the further education programs

Table 1 Higher education quality assessment survey results

Place in the ranking	Education quality assessment procedure	Number of responses among (percentage)	
		Staff members of organizations	Students
1	Graduate employability	25	25
2	Accreditation performed by government institutions	23	18.1
3	Independent quality assessment performed by accreditation agencies and internationally recognized accreditation agencies	22	17.9
4	Assessment of academic performance (learning outcomes)	11	12
5	Internal surveys of students	10	15
6	Rankings	9	12

and pre-school activities) [4]. Federal state higher educational standards (hereinafter referred to as FSHES) that govern the educational program development process have been updated during the past two years and the education quality assessment standards have been changed.

For instance, an obligatory internal operation quality assessment standard has been included into the list of the FSHES. Part 4.6 of the FSHES describes internal assessment made by the teaching staff, employers, their associations and students and the external assessment:

- Accreditation performed by the government institutions is 'the confirmation of the fact that the operations performed in accordance with the program curriculum meet the FSHES and the curriculum requirements';
- Accreditation by accreditation agencies is 'the confirmation of the fact that the quality of graduates' training meets the professional standards' requirements (if any) and labor market requirements'.

The higher education quality assessment procedures diverse depending on the type of organizations conducting the assessment.

- **Accreditation performed by the government institutions.** This is the program accreditation performed by the government institutions, supervision of education system operations (HEI efficiency monitoring) by the Ministry of Science and Higher Education of the Russian Federation.

Accreditation performed by the government institutions means determining the compliance of the program content and education institution's students' training quality with the federal state educational standards. Nationally accredited education institutions have certain special characteristics, incl. the following: male students have a right to have deferment from military service in the Armed Forces of the

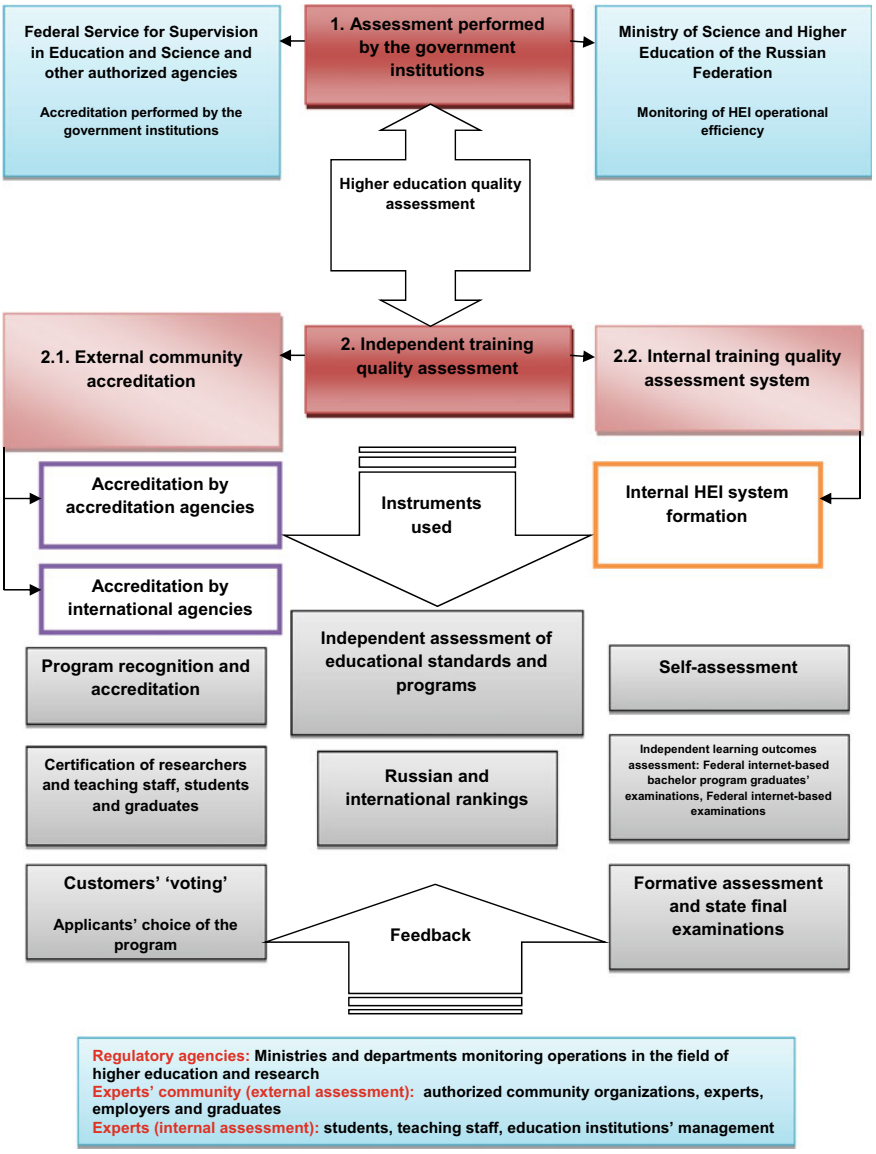

Fig. 1 Russian higher education quality assessment system and its components

Russian Federation for the period of study; the institution has a right to issue diplomas formatted in accordance with the standards determined by the state; the students have a right to use the maternity capital funds when paying the tuition fee, and the students have a right to have their tuition fee expenses covered by the federal budget funds.

Supervision of the operations in the field of education (monitoring of HEI efficiency) by the Ministry of Science and Higher Education of the Russian Federation is a systemic supervision of the learning environment, student cohort composition, students' academic achievement and graduates' achievement in the workplace. Monitoring is conducted in order to provide detailed objective information on the education system to the Russian nationals and the government institutions. The Ministry of Science and Higher Education of the Russian Federation uses the information in order to prepare an annual report to be presented to the Government of the Russian Federation. As of 2014, reports on the regional and municipal education systems have been posted on the official websites of agencies monitoring the educational systems' operations and are freely accessible to the public.

- **Independent higher education quality assessment** means an assessment process that is aimed at obtaining information on the educational activity conducted by the education institution, students' training quality and the program design [3]. Independent higher education quality assessment can be external and internal.

The detailed independent education quality assessment description is contained in the Methodological Recommendations for Making Independent Educational Organizations' Educational Activity Quality Assessment approved on 1 April 2015 by the Ministry of Education and Science of the Russian Federation (circular letter No. AP-512/02 of the Ministry of Education and Science of 3 April 2015 'On Distribution of Methodological Recommendations for Making Independent Educational Activity Quality Assessment') [7].

- **External assessment** is assessment made by the experts (accreditation made by the accreditation agencies, incl. industry accreditation and accreditation be internationally recognized agencies).

In accordance with Article 96 of Law No. 273-FZ 'On Education in the Russian Federation' [3]:

1. Education institutions can be accredited by various Russian, foreign and international organizations;
2. Accreditation means evaluating the education institution's operations and confirming that the operations are in conformity with the criteria and requirements set by the Russian, foreign and international organizations;
3. Employers, their associations and agencies authorized by them have a right to perform accreditation of educational programs (hereinafter PA) offered by the education institution;
4. Industry program accreditation means confirming that the education institution's graduates' training quality meets the professional standards' requirements, and the requirements of the labor market set for the employees who are experts in a certain area.

Industry and international accreditation agencies operate in accordance with the following principles when making independent quality assessment:

- Participation is voluntary;
- The examination process is conducted and accreditation decisions are made independently; no discrimination is allowed and no biased decisions are made;
- The information on the procedures and criteria for assessment and accreditation is open for the public;
- Assessment and accreditation procedure participants' rights are protected;
- The information used by experts is complete and reliable;
- Accreditation agencies are responsible for the results gained by the accreditation agencies during the examination and the decisions made by the accreditation agencies;
- Accreditation procedure results are accessible and open to the public.

National Qualifications Council (NQC) under the President of the Russian Federation founded in accordance with Decree No. 249 of the President of the Russian Federation of 16 April 2014 consolidated the efforts of employers, government institutions, and trade unions in order to develop a national qualifications framework. The NQC examines draft laws and by-laws, drafts of professional standards and coordinates efforts aimed at improving quality of higher education, incl. improvement of industry accreditation of programs of study. Sectoral qualifications councils under the national employers' associations founded by the NQC are engaged in this on the sectoral level.

It should be emphasized that the PA is the recognition of graduates' training quality and the confirmation of the fact that the program meets professional standards. Conformity with the labor market requirements is at the core of the industry accreditation. It should be taken into account the fact that the PA does not coincide with the accreditation performed by the government institutions as different assessment criteria and procedures are used in the PA. The Russian PA can be compared to the international program accreditation procedure. Qualifications councils founded by the NQC, All-Russia associations and All-Russia industry employers' associations and major employers have a right to conduct the PA procedure.

- **Internal assessment** is performed through the internal (university) independent higher education quality assessment system. The key goal is to assess quality of training of the students in the most objective way possible. Each education institution has its own internal quality management system in place (an ISO standards-based quality management system, European standards-based quality assurance system, etc.) However, it is important to emphasize that the independent university higher education quality assessment system should include a certain independent component into each of the assessment events. If such an independent component is lacking, the system cannot be considered to be independent.

The goals of the internal independent assessment system are the following:

- to improve the structure and update the content of the educational programs offered by the education institution;
- to improve the resources used to support the teaching process;

- to improve the competence and professionally develop the teaching staff involved in the teaching process;
- to improve student motivation to learn;
- to improve the interaction between the education institution and the social partners, incl. the employers when discussing program improvement issues;
- to counter corruption in the teaching process.

When building an internal university independent higher education quality assessment system, the universities embed independent elements into the existing higher education quality monitoring procedures. Students' assessment of the higher education quality is undoubtedly an important and significant internal independent higher education quality assessment system element.

Examination of the education systems of other countries shows similar trends in the development of approaches to higher education quality assessment, incl.:

- Student engagement as a basis for standards and assessment methods development. The American national research project NSSE findings prove that the student engagement in the teaching process and their learning outcomes highly correlate (NSSE) [2]. To fulfill their supervisory obligations, the educational institutions' competent authorities should be aware of the meaning of such concepts as the student engagement in the teaching process, they should learn about the students' expectations associated with the higher education quality, and identify the best ways to disseminate information about the learning outcomes [6].
- New formats of flexible learning. A number of new teaching formats and practices emerge as there is a demand for using a more flexible approach to learning on the educational services market. It includes the use of competences-based learning modes, recognition of the learning outcomes obtained by the students of the Massive Open Online Courses (MOOCs), modular programs, recognition of informal learning outcomes, etc. Without doubt, the quality assurance system should change accordingly to the new reality.
- A focus on skills and competencies. Majority of national (incl. Japanese, British, Canadian, and US) governments express concern over the fact that the universities do not produce graduates with the job-ready skills that the economies need in order to provide opportunities for growth, create incentives for innovation, and build wealth. Such university graduates' soft skills as critical thinking, teamwork, efficient communicative skills, ability to learn, problem identification and solving skills are becoming increasingly important for employers. These skills are developed during the period of study of certain disciplines that contemporary universities include in the program curricula [5]. Therefore, the higher education quality assessment procedures should also be flexible, capable of assessing professional competencies and non-academic skills required by the employers.

The globalization process and the increasingly fierce competition have facilitated launch of international higher education quality assurance organizations and processes (Figs. 2 and 3).

Education Area (ESG) (Part 1: Standards and guidelines for internal quality assurance; Part 2: Standards and guidelines for external quality assurance; Part 3: Standards and guidelines for quality assurance agencies).

- the Council for Higher Education Accreditation (CHEA). Standard 1. Promotes academic quality and advances student achievement; Standard 2. Demonstrates accountability for performance and transparency; Standard 3. Encourages, where appropriate, self-scrutiny and planning for change and for needed improvement; Standard 4. Employs appropriate and fair procedures in decision making; Standard 5. Demonstrates ongoing review of accreditation practices; Standard 6. Possesses sufficient resources;
- Ibero-American Network for Quality Assurance in Higher Education (RIACES);
- Asia Pacific Quality Network (APQN): institutional internal and external higher education quality assessment and quality assurance in accreditation agencies' operations.

The approach offered by the ENQA is the most trusted approach to quality assurance and quality assessment in higher education for the Russian Federation, a Bologna Process country participant.

While wishing to harmonize teaching and research, the Bologna Process country participants join their efforts to develop a single approach to higher education quality assurance and assessment. Established in 2000, the European Association for Quality Assurance in Higher Education (ENQA) is a non-profit organization engaged in independent monitoring of education institutions' operations.

In 2015, ENQA presented the Standards and Guidelines for Quality Assurance in the European Higher Education Area (ESG) (hereinafter referred to as the ESG Standards) to the academic community members [5]. Two years of intense work

of all the stakeholders, incl. European accreditation agencies, education institutions, student associations, professional and academic communities were needed to develop the ESG Standards. The document was adopted by the Ministers responsible for higher education in the European Higher Education Area in May 2015.

The ESG Standards consist of three parts [9]:

Part 1: European standards and guidelines for internal quality assurance within higher education institutions;

Part 2: European standards and guidelines for the external quality assurance of higher education;

Part 3: European standards and guidelines for external quality assurance agencies (ENQA, 2015).

All three parts of ESG Standards are closely connected with one another and are the basis upon which the European quality assurance institutions are built.

Internal quality assurance standards include examination of the quality policy, the educational program development and approval process, student-centered approach to training, teaching and assessment, student admission procedure, learning outcomes recognition procedure, academic performance and certification, the teaching staff qualifications; learning resources and student support infrastructure, data management and information distribution procedure, and monitoring and periodic program review.

According to the ENQA recommendations, external quality assessment procedures should be conducted in education institutions in accordance with the ESG Standards on a regular basis. Guidelines for external quality assessment of higher education are described in the second part of the ESG Standards. The following principles and tools form the basis of the standards:

- external quality assessment procedures should take into account the internal quality assurance procedure efficiency;
- external quality assurance procedures should be fit for specific purposes and comply with the by-laws;
- external quality assessment procedures should be reliable and well-defined;
- the external quality assessment procedure should include 3 main stages: analysis of a self-examination report, the external assessment event proper, which, as a rule, includes a visit of a group of experts to a higher education institution, and preparation of a report based on the results of the external assessment;
- subsequent quality assessment procedures should be uniform;
- students should be included into the group of external experts that makes the external assessment;
- decisions made and conclusions drawn following the external quality assessment should be based on published strict criteria, regardless of whether the procedure leads to an official resolution or not.

The third part of the ESG Standards defines the operations of external higher education quality assessment agencies. The agencies should be independent and

autonomous, should have a legal status and be officially recognized as quality assurance agencies. The periodic external review of agencies' operations should be made at least once every five years to confirm their compliance with the ESG standards.

The 2015 Conference of Ministers of Higher Education of the countries participating in the Bologna Process has also developed the European Quality Assurance Register for Higher Education (EQAR). It officially registers higher education quality assurance agencies that comply with the ESG Standards [10].

Another important contribution made by the Yerevan Communiqué signed in 2015 by the Ministers of Higher Education of the countries participating in the Bologna Process was a document titled European Approach for Quality Assurance of Joint Programs. The world's leading universities have been offering the joint programs for a long time as such programs provide an opportunity to students and staff to become engaged in academic mobility programs which contribute to the international cooperation development and harmonization of the EHEA. In accordance with the European approach, the joint program quality assurance is also based on the use of the ESG standards. Partner universities should jointly select an agency that offers external quality assessment services and is registered in the EQAR. The Agency shall in due course interact with the competent national authorities of the countries where the partner universities are located.

In most countries where objective higher education quality assessment systems are developed, such systems are based on a combination of quantitative parameters and good expert opinions.

Quantitative parameters, as a rule, are based on the collected statistical data on all the key university operations. Much attention is paid to teaching, research, and the quality of services provided to the local or regional community. China has gained the best practices here. Using the latest information technologies, it builds its own assessment system based on the generated and examined Big Data.

Universities are placed into quality clusters based on their qualitative indicators. Qualitative assessment is made on the basis of, first of all, self-examinations where immediate and long-term development goals are taken into account; a combination of internal and external university assessments is used. External assessment goes beyond the academic community and takes into account the opinion of employers, industry representatives, and users of university's services.

3 Results

Table 2 systemically shows the characteristics and compares the indicators used in the PA made by the Council for Professional Qualifications of Financial Market Experts and the internationally recognized accreditation made by the European Council for Business Education (ECBE).

4 Recommendations

Despite the fact that directly correlate the criteria-based quality assessment indicators using the methods offered by the ECBE and the Council for Professional Qualifications of Financial Market Experts, generally, the authors observe a certain conceptual similarity of parts of the international and Russian public assessment systems. In general, the goals of international and Russian non-profit accreditation agencies can be described as follows:

1. To assess the actual learning outcomes achieved by the graduates.
2. To assess the quality assurance policy that the education institutions demonstrate to the students.
3. To identify and examine the educational program advantages and disadvantages.

Table 2 A comparative analysis of indicators of international program accreditation offered by the ECBE (based on the ENQA principles) and industry accreditation offered by the Council for Professional Qualifications of Financial Market Experts (based on the principles of the Presidential National Council for Professional Qualifications)

Criteria and indicators used in the assessment process	
ECBE	Council for Professional Qualifications of Financial Market Experts
Compliance with the quality standards	Groups of indicators; detailed criteria used in assessment
General view of the university quality policy	
1. Availability of the quality assurance rules and procedures, which should be published and be part of the strategic management system 4. Consistent use of predefined and published rules of the student lifecycle starting from the student admission, including the teaching process, recognition of the award and certification 6. Appropriate funding of the teaching process and a guarantee that appropriate timely support is provided to the students, and learning resources are available and accessible 8. Availability of information about the university operations, including educational programs, which should be clear, accurate, objective, relevant to reality and accessible 10. Periodic external quality assurance reviews are organized in accordance with the Standards and Guidelines for Quality Assurance in the European Higher Education Area	7. Additional criteria. Integration of teaching, research and practitioners' requirements with the educational program content. Quality of educational activity in the education institution is recognized

(continued)

Table 2 (continued)

Educational program design and realization (Efficient program portfolio management)	
2. Availability of the educational program development and approval procedure. Programs should be fit for purpose, including specific learning goals. The training provided within the program should be clearly defined and made public, and be in line with the national qualifications framework related to higher education, and the education system in the European Higher Education Area 7. Collection, analysis and use of relevant information for the efficient educational program and other operations management should be ensured 9. Monitoring of the status and periodic review of educational programs in order to guarantee goal achievement and meeting the needs of students and the community. Such a review should contribute to continuous program improvement. The stakeholders are informed of all operations that have been performed or are planned after the review	1. Educational program planned learning outcomes meet the professional standards' requirements. 2. Educational program content meet the professional standards' requirements 4. Confirmed employers' participation, including major company representatives, in the educational program development and offering
Student engagement in the quality assessment system	
3. A guarantee that program teaching is conducted in such a way that the active student engagement in the teaching process development is encouraged, and that such an approach is reflected in the students' assessment	–
Confirmation of compliance with the labor market requirements	
5. A guarantee of the teaching staff good qualifications. Use of fair and open staff recruitment and professional development procedures	5. Completion of an independent student and/or graduate higher education quality assessment procedure
	3. Adequacy of financial, technical, ICT, learning and methodological resources that make a direct impact upon the graduates' training quality
	6. Demand for an educational program, an employers' demand for the graduates of the educational program, including major companies' representatives

4. To assess how the programs relate to the international education system development trends, incl. program development based on the expected learning outcomes; program development based on the research findings, the maximal use of the research findings in the learning process; employment of highly-qualified and competent teaching staff, etc. [8].
5. To assess the compliance between the training offered to the graduates and the industries' standards requirements, the international, national and regional labor market requirements set for experts in a certain field; national and international qualifications frameworks' requirements.
6. To assess whether the program directors track and take into account the changes in the program content and higher education quality requirements set by the employers and the labor market.
7. To assess the program efficiency in terms of the graduate employability, employment and career development.

The key difference between the approach used by the ECBE and the Council for Professional Qualifications of Financial Market Experts is that in the ECBE methodology, the emphasis is placed on the student satisfaction with the higher education quality and student participation in the assessment. Industry accreditation methodology proposed by the Council for Professional Qualifications of Financial Market Experts, first of all, stresses the necessity of taking into account the employers' (labor market) satisfaction with the quality of graduates' training. The employers' important involvement in all the stages of the teaching process (from the program design stage to the learning outcomes assessment) is in focus here.

Acknowledgements The article is based on the results of studies carried out at the expense of budgetary founds under the state order of the Financial University under the Government of the Russian Federation for 2018.

Iterations of Digital Transformation of Human Capital in the Development of Economic Growth Drivers

Roman S. Blizkiy, Valentin E. Malinenko, and Yuliya S. Lebedinskaya

Abstract This article is devoted to research of potential, new discussed problems of iterations of digital transformations and their influence on human capital. The research is aimed at systematization and justification of key iterations of digital transformations of human capital in the development of economic growth drivers. Results: (1) The terminological apparatus of the concept "human capital" is revealed. (2) The main trend iterations of digital transformations, their properties and degree of influence on the transformation of human capital are considered. (3) The author's concept of the four-level model of interrelation of building an effective model of adaptation of human capital in conditions of transformation of the nature of work is presented. (4) The neoclassical paradigm describing iterations of digital transformations of human capital, consisting of structural and logical processes influencing the growth of economy, is proposed.

Keywords Human capital · Digital economy · Institutionalization · Human development · Neoclassical paradigm

lies a struggle of interests between the introduction of new technological solutions, innovations and the wide involvement of human capital in the formation of the added value of the final product or service. The results of studies by Gomina and Mestieri [4] showed that today, on average, the deviations between countries in terms of the level of technological development reaches 42 years, which demonstrates the problem of significant differences in coherence, interaction and transformation of human capital at the interstate, global level.

2 Reference Information and Methodology

The modern point of bifurcation of world iterations of digital transformations of human capital, on the one hand, represents: fundamental and applied scientific discoveries, a level of interaction of SMART technologies and digital platforms, robotization and automation of production and service cycles, clustering of separate directions of non-typical employment including development of gig economy, a level of health and education of the person. On the other hand, it faces asymmetries of social security, insufficient flexibility of adaptive-institutional support, development of institutional isomorphism, significant differences in intercountry productivity, limited realization of labour rights, and an unbalanced system of effective management and business management. All these iterations of digital transformations of human capital caused the establishment of the foundation of scientific research and search for the connection of the congruent socio-economic environment and cognitive dissonance of social reactions, in the conditions of the development of growth of the world economy.

Theoretical and methodological basis of research is formed by the positions of economic theory, regularities of development of digital economy, international research in the field of development of human capital, scientific works of foreign scientists-economists on development of economic growth drivers.

Methodological tools used in the paper: systematic and complex approach to research iterations of digital transformations of human capital in dialectical unity with the development of growth drivers of the world economy. In the work the general scientific and special methods are used, which have allowed to define components, processes and interaction of historical dilemmas of iterations of human capital transformations and to allocate a model of multilevel effective adaptation of the human capital in the conditions of transformation of character of work are used. In particular, the methods of retrospective analysis, the system approach and the institutional-evolutionary method were used to study the formation and development of iterations of human capital transformations. In defining features and problem-solving issues the researchers used content analysis; in studying the consequences of digital transformation, robotization and automation they applied economic analysis; in the study of the state of inequality, level of education and health of human capital economic-statistical (graphic) method was used. Preparation of proposals and recommendations was carried out through system-structural method and methods of

social imitation in terms of subjective process of assessment of social deviations and society's response to them in the conditions of socio-cultural reality of the digital economy transformations.

3 Discussion and Results

The process of transformation and implementation of technological innovations has historically been accompanied by resistance and rigid dissonance of public reactions. Keynes [10] drew attention to the consequences of technology in the form of mass unemployment. In 1930, Keynes [11] said that in 100 years' time, thanks to new technologies, there would be an era of leisure and abundance. He believed that everyone would have to do something to enjoy life, but that three hours a day would suffice.

According to a sociological survey conducted in 2017 by the Center for Public Initiatives "Special Eurobarometer 460" [15], about 75% of European citizens indicate a positive perception of the introduction of new digital economy technologies as a kind of good that improves their future. The first consequent historical dilemma of the iteration of confrontation between the "man" and the "machine" lies in the search for an answer to the question: What new technological changes does human capital expect and what will they lead to on the way to forming new heights of capitalization of funds and increasing the assessment of the value of the company as one of the drivers of economic growth?

At the beginning of the twentieth century, the business model of companies' development was set within the limits of certain boundaries of their interests, and it was usually within the territories of cities and districts. Coase [3], in his scientific paper "The Nature of Companies", noted the specifics of increasing the size and scope of companies, where the basis for the expansion of production processes was provided by the factor of comparability of investments (costs) of own forces in comparison to the analogue of costs in the open market. The scale of activity of modern companies under the influence of digital transformation, globalization, international trade agreements on free trade, new information technology initiatives and other introductions of human progress have significantly changed the possibilities of business processes of companies—now they conduct operations where and when it is more profitable. Thus, the transformation of the degree of vertical integration of companies allowed more and more functions to be outsourced and freelanced. There is a second iteration of human capital transformation in the background of competitive struggle—new forms and models of doing business (including those blurred within different countries) in contrast to classical forms of functioning, new forms and models of business which are less dependent on human capital.

The founder of economic theory, Smith [14] believed that the acquisition of abilities, upbringing, training or apprenticeship, always require real costs, which are fixed capital, that is allegedly realized in the person. These abilities, being part of the state of such a person, also become part of the wealth of society as a whole.

Thus, we consider the following author's definition as comprehensively balanced, in the narrow sense: Human capital is a reasonable set of knowledge and skills, health and survivability, education and culture, which are accumulated over the course of human life and allow the individual to develop their potential as useful properties and results of development in society.

The current state of education and health of the world population has increased along with technological advances and scientific discoveries. The human assets index has changed considerably over the past forty years, reflecting significant improvements in achievements such as life expectancy at birth, including reductions in extreme forms of deprivation. The derivation of increases in global life expectancy rose to 65 years [16].

Therefore, there is a historical dilemma between the perception of iteration of the process of creating an additional product (value) at an early age by a person and his ability to develop as a full person with secondary vocational education or higher education to further develop the potential and increase the value of human capital.

Relevance of research of human capital, which possesses complex properties of an emergent system in the conditions of implementation of the concept "Industry 4.0", as well as the transformation of growth drivers of the economy, is of particular interest when considering iterations of the properties of their orderliness and self-organization, explaining the development of complex from the simple and the emergence of order out of chaos.

Today the information environment of human life is saturated with compression and acceleration of "time" and above all in the field of creation, movement and use of information. According to the report of the Director of the BRICS Antimonopoly Center voiced at the VI BRICS Competition Conference [2], in 2019 Russia ranked eighth in the world by Internet users (109.5 million users). In 2019, according to the International Telecommunication Union [8], more than 3.9 billion people, or 51.2% of the world's population, already accessed the Internet. The growth dynamics for 2019 as compared to 2015 shows a significant increase by more than 700 million new users. When researching the dynamics of changes in information flows of Internet users, the following things attract scientists' attention: analytical model of complex-system assessment, demand for hosting, reliability of web sites, popularity of sites and digital platforms in the world presented by the Russian company TAdviser [13].

The dynamics of information flows today transform the reflexion of the human being by changing their perception, consciousness and behaviour. Scientists of the world constantly discuss the problem of Internet addiction, problems of psychological reaction and manageability of a person. In 1969, the American psychologist Kübler-Ross [9] proposed a model of the human emotional state, and in 1996 the model of Weiss's adaptation process appeared [18, 19] as we see it, the search for ways and approaches to manageability and adaptability of a person in the modern society sphere is stable.

The World Development Report 2019, prepared by World Bank staff [17], notes the complexity of adapting a new generation of workers to the jobs, as they, above all, require specific social protection programs at the state level. Globally, only 2 out

of 10 people in developing countries receive social assistance and only 4 out of 10 work under health insurance guarantees.

One of the protection trends is the establishment of a social protection floor sufficient for the society to enable a person to receive assistance regardless of employment status. In this case, the effectiveness of the social protection system can be improved by extending its overall coverage in order to include, first of all, those members of society who need it most, and by increasing the role of state participation in socially significant projects, for example, through proactive budgeting.

To develop maximum benefit to society in an era of discovery and technology development, a new socially oriented convention is required, in which the fundamental element is to increase investment in human capital and to work in a phased, systematic way to create social protection. Against the backdrop of the growing need to create a soft "airbag" in new jobs, the transformation of the components of human capital requires greater authority on budgetary rules of administration and compliance with modern challenges of an insufficient tax base, large-scale shadow schemes in the economy and inefficient control over budget spending.

Let us consider some distinctive features of a modern stage of digitization and a condition of a technological paradigm objectively influencing formation of digital economy with increase of certain degree of synergy effects in the field of the human capital:

(1) First of all, digital platforms, trading platforms are new business management models (platform models) characterized by blurring the boundaries of the company, successfully competing with outdated models of local production. The positive point is the process of activating digital platforms, which allows to increase the growth of efficiency indicators in the world with much less investment in material or human resources. The negative point is the virtual orientation and location of business model production assets, which affects three categories: confidentiality, competition and taxation. Influence on the human capital by changing the demand for work skills increases the value of cognitive skills of the highest order. It also changes the perception of investing in human capital with three components: cognitive development, social behavioral skills and a set of skills that predetermine adaptive capacity. Governments that are in the transition to a technological shift that is changing the nature of work are seeking to invest in human capital as the only right solution to a mass of uncertain factors in the future environment. Table 1 presents data on the main processes of interaction of all elements in the transformation of the nature of work.

There are different levels of impact on adaptation measures of key elements of human capital in this model. This statement is based on the theory of social simulation in terms of the subjective process of assessment of social deviations and reactions of society, as well as taking into account the properties and characteristics of the methodology of the index of human capital.

(2) Secondly, changing demand for low-skilled (simple) labour of a worker—new technologies displace and change (reduce) the need for those skills that can be replaced by advances in technological evolution: automation and robotization.

Table 1 Level relationship of the main construction parameters of an effective model for adapting human capital to the changing nature of work

Transformation level	Order of levels	Adaptation measures	Up-to-date human capital index track
1.Goal		People in demand, competitive markets, new socially oriented contract	Health (Hlt) Education (Ed) Survivability (S)
		Hlt Ed S Hlt Ed S Hlt Ed S	
2.Social integration	1	Efficient service procedure, fair taxation, inclusive business model management	
		Hlt Ed S Hlt Ed S Htl Ed S	
3.Politics	2	Investments in human capital / Importance of social protection / Transparent model of revenue mobilization	
		Hlt Ed S Hlt Ed S Hlt Ed S	
4.Consequences of the introduction of new technologies	3	Changes of skills / Establishment of fair social guarantees / New business management models, platforms	

An increase in demand for cognitive social behavioral skills and the tendency to reduction of demand on low skilled workers on labour markets are considered to be positive changes. However, the situation with increased competition between man and machine, where flexibility and speed of adaptability to changes will be decisive factors in time, is considered negative. Therefore, the spillover of human capital (labour migration) from one labour location to another according to a number of criteria will increase, which will lead to different forms of related negative side effects associated with skewness (oversaturation, urbanization, conglomeration) in ensuring social security of people. Influence on the human capital is expressed in the following way: skills for complex problem solving, teamwork, and development of logical thinking will change the requirements for development, primarily intellectual values in a person, rather than physical capabilities.

A wide range of forecasts suggests that it is difficult to assess the impact of technology on employment. Most estimates are based on automated probability calculations by machine learning experts at Oxford University's Blavatnik School of Government [12]. Specialists in 2018 were asked to evaluate a sample of 70 occupations in the online database of O*NET occupations used by the U.S. Department of Labour, from the point of view of whether or not they were fully automated.

(3) Thirdly, robotization [7] as a process of transformation of automated processes into a more complicated, complex algorithm of operations per unit of time will significantly change the attitude to productivity and cost of production. Based on the scientific discoveries of American scientist Ashey [1], it can be noted that the introduction of robotic processes of machine learning in the economies of countries has already started. According to the International Federation of Robotics [6], Figs. 1 and 2 provide information on the dynamics, volume and trends of the robotics market in the world. The dynamics of the presented information testifies to the rapid growth and huge potential of this area, which should create new conditions and opportunities for human development.

The positive aspect lies in the fact that optimization of factors and means of production, intensive way of increase of production capacity and active support of development of robotization will lead to improvement of quality of performed works, productivity, exclusion of the human factor and change of structure of the workers occupied in industrial (dangerous and harmful) branches of digital economy. The negative aspect consists in the absence of a new socially oriented contract, a soft

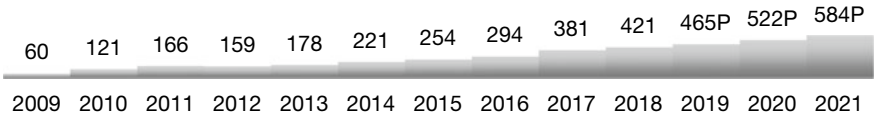

Fig. 1 The dynamics of installed industrial robots in the world for 2009–2018 and forecast for 2019–2021, thousand units

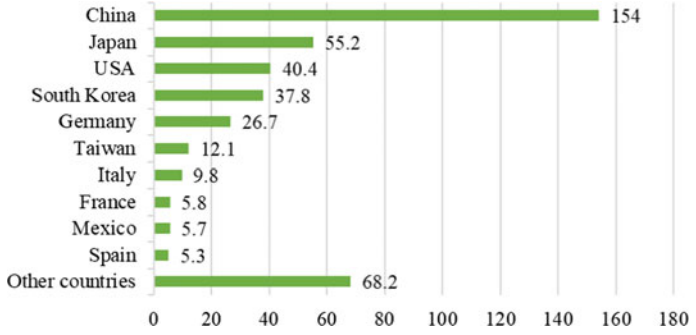

Fig. 2 Top 10 countries in the world for the implementation (installation) of industrial robots in 2018, thousand units

"airbag" in new workplaces during the transformation of human capital components will lead to mass unemployment.

(4) Fourthly, the existence of low-productive labour, in the informal sector of companies whose access to new technologies is limited. According to ILO [5], over the last decades unreported employment has remained high (over 60%), even with the improved requirements of the regulatory environment for the introduction of business.

The impact on the human capital is expressed in changing demand for labour skills, increasing the value of institutional regulation, transparency and accessibility in resource redistribution.

(5) Fifthly, modern technology and, in particular, social networks, affect the perception of growing inequalities. In an effort to improve the quality of life, people take an active part in the economic growth of the state. Thanks to social networks and other digital means of information exchange, a person can compare various and often fundamentally different lifestyles and opportunities of people (from different states, social classes, etc.). Where aspirations are combined with opportunities, there is an enabling environment for sustained economic growth that benefits all segments of the population. But where there is inequality of opportunity or a mismatch between jobs and skills, frustration can lead to migration or fragmentation of society.

4 Conclusion

Human capital from a methodological perspective is viewed as a systemic, multi-level phenomenon, accumulating a set of knowledge and skills, the level of health and state of survivability, the quality of education and the position of culture throughout human life, allowing a person to develop his or her potential as useful properties and results of development in society. Thus, the formed author's review of positions of iterations of digital transformations of human capital in dynamics of development of growth drivers of economy, and also the four-level model of interrelation of the basic parameters of adaptation of human capital in the conditions of transformation formed by the author's team allow to form author's neoclassical paradigm of the description of iterations of digital transformations of human capital consisting of structural and logical processes. The author's scheme (Fig. 3) of neoclassical paradigm of iterations of digital transformations of "human capital" and interaction of processes causing efficiency of human saving as a complex process which is formed under the influence of technological, digital, political, educational, physiological, social-economic, cultural and social-ethical factors of quality of his or her life is formed.

The Digital Potential of the University: Notion, Structure and Methodological Principles of Assessment

Dmitriy Yu. Znamenskiy, Vera A. Suvorova, and Vladimir A. Volokh

Abstract The purpose of the article is to substantiate the "digital potential of the university", as well as the principal methodology for its assessment. The authors understand this term as the ability of the university to use advanced digital technologies in the production and transfer of new knowledge, as well as to make educational and scientific achievements in the digital economy and artificial intelligence. The author's methodology for investigating this phenomenon lies in the system-dynamic approach to the consistent description of internal and external factors of developing the university's digital potential, forms of unlocking it and predicting fundamental prospects of further development. The key finding of the article is the author's presentation of the structure of the modern university's digital potential, as well as the principal method of its assessment. This technique can be used in the monitoring of university performance conducted by the Ministry of Science of Russia, as well as in independent assessment operations by civil society institutions.

Keywords High school · University · Digital economy · Digitalization of high school · The digital potential of the university

1 Introduction

The current importance of the study on the digital potential of modern universities is associated with the development of management technologies in higher education

(including the management of the educational process), as well as the general trends of the emerging digital economy in Russia and the world. This problem is addressed today in Russia [1–4] and in foreign science [5]. However, the integral theory of the digital economy has not yet been developed, its methodological background has not been laid, and the category framework has not been established [4].

The idea of a digital economy dates back to the mid-90 s of the last century. One of the first new terms concerning new trends of the global economy has been worked out by the Canadian economist and business consultant D. Trapscott. N. Negroponte was the first to emphasize the peculiarity of the digital economy as a system based on virtual economic ties and global traffic of information, goods, services, and funds [6].

As for domestic science, V. A. Wainap provided the most simplistic but exhaustive definition of the digital economy. He understands it as the system of economic relations where digital data is a key factor in production [7]. A. Engovatova interprets the digital economy almost in the same way and highlights the use of new methods of data generation, storage, processing, and transmission, as well as digital computer technologies as the main features [8]. D. N. Evtyanova, describing the digital economy as automated economic management based on advanced information technologies and as a new economic order premised on efficient information management of production, think slightly differently [2].

It seems to us that the interpretation given by the above author is applicable to university management, which allows talking about its digital potential. However, here we deal with the problem. To date, there is no common concept of digital potential and an integrated methodological approach to its study.

2 Methods

The basic premise of the authors in defining digital potential is to recognize the narrowness of purely resource approach to the interpretation of “potential”. To be sure that the digital potential covers a much wider range of phenomena, processes, relationships, and factors that cannot be impartially evaluated only through analysis of resources. We pay the highest attention to this issue because it is dictated by the author’s methodology and practical needs.

Nevertheless, a critical understanding of even not exactly correct points of view allows taking a qualitatively new level of generalizations, proving the author’s standpoint on the initial theoretical and methodological points of study. We see it reasonable to make some etymological digression, which points at the Latin roots of the term “potential” (lat. Potentials). The Russian language got this term in the nineteenth century from French sources, where the word “potential” comes from the word “potens” (literally—“could have been”), which is recorded in the etymological dictionary of the Russian language. Most often, the above term is interpreted as “sources, opportunities, means, reserves that can be used to solve a problem, achieve

a specific goal; the abilities of an individual, society, and state in a particular field." [9, 10].

The main approach of the author to defining the digital potential of the university lies in understanding it as the ability of the university, firstly, to use advanced digital technologies in the production and transfer of new knowledge and, secondly, to make educational and scientific achievements in the digital economy and artificial intelligence.

Given this interpretation, one should not forget that this ability is not automatically delivered, but should be controlled. This basic parameter determines the subsequent path of analysis. It seems that the methodological basis for the study of the university's digital potential can be the system-dynamic approach, proved many times when investigating the problems on the management of academic institutions [11]. In this particular case, the application of the principles of system dynamic trend means a consistent analysis of internal and external factors in developing the digital potential of the university and the forms of unlocking it and predicting the fundamental prospects of its further development. The essence of the system-dynamic approach defines three key dimensions of the university's digital potential (spatial, process, and technological).

There is no doubt that all of the above phenomena and processes are inextricable. For example, the digital potential is simultaneously developing in space and time, which is associated with the use of various technologies, including assessment and methodological plan. The dialectic of real life impersonally establishes the inextricable relationship between dimensions of digital potential, which by all means suggests their synthesis in the theoretical and methodological terms.

3 Findings

The spatial component of the digital potential is a combination of factors aimed at its development, including institutional, structural, physical, financial, human, and social ones. Along with that, above all it is worth highlighting: (a) research units (laboratories, centers) and administrative bodies responsible for the digitalization of both educational and research activities in the structure of the University; (b) the scale of digital technologies integration into learning process (for example, the use of electronic document flow systems, mobile applications, etc.); (c) the attention of university research staff to the issue of the digital economy's development (for example, the number of applications on relevant topics submitted for scientific grants, or participation in scientific conferences on the issues of the digital economy).

The strong stand of the authors on this matter is that the institutional foundations of the university's digital potential can be structured at three levels (the university as a whole, the department, and the chair). The university level, in turn, is the unity of three sublevels, namely strategic (represented by the founder of the university, board of trustees, academic council, and rector), operational management (which involves the research and methodological council of the university and vice-rector

in this area), executive level (consisting of the university unit, temporary creative teams, working groups of the university project, etc. responsible for the digitization of research and educational activities), the departmental (inter-departmental) level is represented by the academic council of the department, the dean, as well as research bodies and working groups responsible for the digitalization of the learning process. As for the chair level, the leading role is assigned to the heads of departments, as well as their deputies for educational, methodological and scientific activities.

Local documents and rules governing the use of digital technologies in the learning process and the research activities of the university include the university charter, development strategy; educational programs developed at the university; guidelines for the use of digital technology in the learning process; regulations on research activities at the university; regulations on academic units and scientific bodies; regulations on departments and chairs; plans for scientific and technological practices; regulations on scientific grants, competitions, exhibitions, conferences, etc.

The resource component of the digital potential is no less important. The following types of resources should be allocated: (a) information; (b) staff; (c) inventory and logistics; (d) funds. The first point includes the entire range of scientific, methodological and practical developments in the field of digital technologies owned by the university in accordance with intellectual property rights. They can be used in the learning process or scientific research (for example, patents, registered university professors). The assessment of human resources should take into account the number of tutors and researchers having scientific publications on the digital economy or teaching relevant subjects, as well as ones submitting for grants in this subject. The system of inventory and logistics obviously should include the cost of equipment designed to ensure the performance of scientific research and the learning process using digital technologies (for example, 3D printers, multimedia projection equipment), supercomputers, related software, etc.). Here it should be regarded the total area to place the scientific laboratories and other units related to the university's digitalization). The key indicators of financial resources of digital potential should include the stock of own assets spent by the University on projects concerning digitalization of the learning process and funding of relevant research and development.

The time component of the digital potential, in turn, reflects the main stages of its life cycle, including (1) the establishment of an appropriate institutional structure; (2) development and approval of regulatory documents governing the use of digital technologies in the learning process and scientific research; (3) recruitment of university staff who know how to apply technologies; (4) laying the essential resource (logistic, informational, financial) background; (5) the current performance of the university's digital environment and achievement of various results (accumulation of new knowledge, results of intellectual activity, innovative technologies, products, etc.) (6) the development of the university's digital potential on the back of evaluation findings.

The content of the most productive (fifth) stage is revealed in forms of unlocking digital potential: (a) institutional; (b) certification and status; (c) scientific information; (g) innovative and (e) financial.

The institutional forms can be clarified in the following areas: (1) recognizing the university as a leading scientific center in the field of digital technologies; (2) holding regular scientific and practical events (conferences, workshops, etc.) on relevant topics at the regional, national and international levels; (3) launching at the university of small innovative enterprises, research and educational centers and other bodies designed to transfer digital technologies and their introduction in the learning process.

The following set of forms to unlock digital potential comes down to certification and status issues. As practice shows, the main forms in this group are (1) the university has a recognized scientific school in the field of digital economy; (2) defense of Ph.D. and habilitation theses on the specified topic; (3) availability of state and public, scientific awards, honorary titles, etc. for achievements in the digital economy among participants of university scientific research.

A form such as officially registered rights to the results of intellectual activity in the field of the digital economy and their introduction in the real sector of the economy or the learning process is equally important for the transition to the digital university. A particular role here is played by inventions, utility models and industrial designs, that is, industrial property. It is commonly known that the protection of intellectual rights to the industrial property is granted by the patent. Therefore, when assessing this form of unlocking the digital potential of the university, we should focus on (1) the number of these patents registered by the University staff and (2) the number of intellectual property items introduced into the learning process. Besides, we should regard the commercial facet of this issue, namely the number of licenses issued for the sale of patented intellectual property and the return from this issuance.

Scientific and information results are also a significant and easily measurable form of unlocking the university's digital potential. This form most accurately presents the integration of the university into the system of global scientific and pedagogical cooperation. The ground-breaking changes both in methods and the scale of monitoring the publication activity of scientists are universally recognized. At the same time, not only conventional forms of research materials (monographs, articles, abstracts of scientific reports) but also new documents of applied character (reports, preprints, abstracts, etc.) are being introduced into scientific discourse. However, in addition to the publications, authors citation indices are of great importance as a manifestation of their contribution to science and the recognition of their findings by the scientific community.

When studying the issuance of scientific and information content as a form of unlocking the digital potential of the university, it seems expedient to distinguish two components: (a) various types of publishing activity directly related to the publication of scientific findings concerning digital economy; (b) the diversity of the university's publishing activities, laying the ground for scientific discussions on digitalization of society.

Finally, the return from the fulfillment of the digital potential is mainly classified by source.

A generalization of modern university practice makes it possible to distinguish: (a) funds from the federal and regional budgets allocated for accomplishment of state tasks concerning scientific research on the digital economy issues; (b) funds from

the federal and regional budgets allocated in the framework of federal, regional and departmental target programs on a competitive basis (for example, Digital Russia); (c) funds allocated by state scientific funds (for example, the Russian Scientific Fund); (d) funds gained from corporate clients and individuals; (e) funds won by participating in international research projects.

The last, sixth stage includes the further development of digital potential, including refining the organizational structure, incrementation of resources, advancement of manpower, etc. Definitely, this development is inextricably linked with the analysis of digital potential assessment, which, in our opinion, should be carried out at all stages of its life cycle.

From the above said follows the importance of the third technological dimension, which encompasses the whole range of technologies for the development of digital potential, its fulfillment (i.e., applications in the education and research) and the assessment of efficiency.

In this regard, the statement by A. A. Turovskiy seems to be true. He notes that the main resource of the digital economy as such and at the same time a key criterion for its development are information and communication technologies (ICT). In the author's opinion, they are directly involved in the forging of new socio-economic, political and cultural ties [4]. The university environment is no exception.

Summarizing the foregoing, we should remark that the establishment, fulfillment, and development of the digital potential in a modern university requires an integrated managerial impact through scientifically based qualitative and quantitative assessments that permeate all stages of its life cycle.

This allows judging about its efficiency and predicting the path of its further development. The key importance of digital potential is explained by that, on the one hand, it is a concentrated expression of the innovative development of any modern university, and on the other hand, the prerequisite for its integration into the national innovation system.

4 Conclusions

After the presentation of the author's methodology, we see it appropriate to describe in brief the key components of the interpretation, which will be consistently and thoroughly discussed in the future.

So, the factors of the university's digital potential are inextricably linked with the phases (with sub-stages) of its life cycle. The first stage involves the establishment of the institutional, organizational and social foundations of digital potential; at the second stage, the established bodies and institutions are provided with physical, technical, informational, financial and other resources; at the final stage, the developed system is integrated into the national innovation system. Using the chronological algorithm arranged in this way, one can classify a set of internal and external factors influencing the development of the digital potential in a modern university.

In view of the above stated, we are convinced that the initial assessment of the university's digital potential is an assessment of the factors of its development.

The ability of university staff to use the available set of factors for scientific and educational achievements is manifested in the fulfillment of digital potential. The fulfillment implies a combination of forms to produce the corresponding goods and relates to their transfer. The range of possible forms is pretty wide.

In the context of the above mentioned, the essence of the secondary assessment of the university's digital potential, which in contrast with the primary one, is aimed at assessing the forms of its delivery, i.e., the outcomes of research activities, is more clearly manifested.

Thus, the author's understanding of the university's digital potential presented in the article allows us to develop a fundamental methodology for its assessment, which can be used to monitor the performance of the Ministry of Science and Higher Education.

Psychological Readiness of Students for Digitalization of Educational Process

Tatyana S. Putilovskaya and Gulnara M. Kassymova

Abstract The purpose of this article, analyzing the core of digitalizing the education process, is a review of the extent of students' readiness for starting a new platform and for taking part in the education process that is based on the use of information and communication technologies and digital technology. As the subject of analysis, the authors chose the sphere of studying a foreign language as an academic subject in the framework of a higher education program, in which digitalization causes an ambiguous attitude, both from students and the teaching community. Overcoming the negative attitude towards the digitalization of teaching foreign languages is one of the prerequisites for considering this issue. Recalling the work of IT specialists, the authors describe the basic directions for digitalizing. The first is the development of information sources (content). The next is the formation of telecommunication system (interaction). And the third direction is an organization of education process (management). In considering the term «psychological readiness», the authors rely on psychological research, in which scientists explored the use of this term in different kinds of activity. When the authors explored the nature of psychological readiness, they conducted a survey and analyzed the students' written works. As a result they got some information that shows the level of students' readiness for digitalizing education. That has led to a series of findings which confirmed that in general students treat the digital revolution in education system in a positive way. But they should be more active, autonomous and well-organized for full and effective functioning in the new environment. The article includes specific recommendations for the organization of education process aimed at language acquisition in the new environment: learning and realizing what digital revolution is, gradual entry into digital education platform, psychological preparation for the new learning conditions on a transitional stage and the support of educational technology referred to as «Blended Learning».

1 Introduction

Digital economy as one of the central factors of human development in the XXI century implies forming fundamentally new information space, the development of information and communication infrastructures and the creation of modern digital technologies. Education as one of the areas of society development is influenced by these processes. It is responsible for preparing qualified staff and education is an essential condition for overall formation of digital economy. Digitalizing of education is not just transition to an entirely new technology system of data processing, obtaining and storing. It is training the future generation in skillful use of these technologies in a way that will not create any psychological rejection coming from members of the education process. It should also serve the common interest of increasing effective and high-quality preparation of staff for all branches of economy.

Success of digitalizing the system of education is based on the extent to which the education process members' are ready for the perception and adoption of the technology revolution. Complex human psychological nature should adapt to the significant change which is related to the process of education digitalizing. For the idea of digitalizing to be implemented without any psychological barriers or problems it is essential to analyze all the specific features and difficulties. It is also necessary to work out and develop the mechanism of adoption and effective use of digital economy achievements.

This article has two main objectives. The first is to analyze the directions, factors and requirements which are related to digitalizing education process using "Foreign language" as an academic discipline as an example. The second objective is to identify the term «psychological readiness» in a broader psychological context and explain the meaning of the concept with reference to the students involved in digitalizing education process.

The novelty of this approach lies in the fact that the subject of analysis is the process of learning a foreign language, which, by virtue of its specificity, involves significantly more reliance on real communication in the course of practical training than any other subject. Therefore, the development of such a balanced learning model that would modernize the educational process using the possibilities of digitalization and retain the ability to learn the language as means of real communication becomes especially relevant.

2 Methodology

This article is based on traditional methods of scientific analysis of the issues to be examined, i.e. analyzing digitalization of education, on the one hand, and analyzing the students' psychological readiness for the adoption of new changes, on the other hand. The research is based on such methods as monitoring, exploring of the interdependence of phenomena, as well as the method of questionnaire surveys and the analysis of the State University of Management students' written works. These methods were targeted toward the detection of the student subjective attitude to digitalization of education.

3 Digitalization in Education

The term «digitalization» is associated with the name of the American researcher Nicholas Negroponte, who first used the concept of «digital economy» in 1995 [1]. Digital economy is about getting data, data processing and use of the results of the analysis, which can increase the effectiveness. That let increase the effectiveness of all branches of economy. Digital economy means the transition to a new organization model of production and management based on information technology.

Informatization is associated with the use of the latest technologies to accelerate and optimize communication processes and saturate educational systems with information products [2], whereas digitalization also involves the partial replacement of a person as a participant in a number of processes with artificial intelligence. And this already entails the death of a number of professions, labor functions and significant changes in the labor market.

That factor is one of the key points, which determines the way people treat digitalization as a challenge of the XXI century [3]. On the one hand, people understand the imminence and usefulness of the ongoing processes. On the other hand there is an element of suspicion concerning digitalization, which depends on the age, the kind of activity, the level of technology literacy etc.

Particular attention in this article is given to digitalization of education, which is considered to be the main Russian education trend and which is regarded today as one of the directions of public policy [4–6]. It is sufficient to note that the last generation state standards in education focus on using of digital technology, the creation of electronic education systems, on-line courses and learning platforms. Now it is possible to speak about general directions for digitalization in education although these changes are still being implemented.

First of all, it means the creation of information resources which accumulate the content of education process [2]. The resources include new teaching materials (training manuals, audio and video tutorials, supplementary media resources, electronic library and data bases of different professional and scientific communities)

which are accessed on-line by all the members of education process. This information can be placed on specific portals or web-sites of the educational organizations.

Secondly, as a trend of digitalization there appear on the internet various telecommunication systems which provide communication between members of education process and organizations [7]. And these systems allow us to conduct different events such as teleconferences, videoconferences and webinars. They also make it possible to get connected to the information networks, data bases and forums with any further exchanges on professional problems and exchange of views on the forums, chats, etc. These opportunities expand spatial and temporal scales of education and communication process and bring it closer to the users of the education services.

Thirdly, digitalization allows to organize the management of the educational process in a fundamentally different way [2], uniting all its participants in a single community, creating appropriate databases, including personal data, information regarding the results of the main activities within the educational process, personal achievements, participating in various events etc.

Managerial sphere includes web-sites, an account on the sites, personal rating, online dean's office, test system with different academic disciplines and even personal information spaces.

In addition, specialists mention the appearance of new opportunities, for example experiments with virtual models, processing the results of the experiments and even organization of intellectual leisure for students [7]. The authors also note that digitalization of the educational process changes the way of providing information and the content of training [8].

A few decades ago we could not even dream of all these opportunities which are becoming a feature in our life and significantly expanding the education process providing access to extensive databases. These opportunities allow us to spend less time on different activities making education more effective and less labour-intensive.

In parallel with these processes, there is a rapid development of modern technologies which give access to all the content, and educational institutions in the country become technologically equipped. At first sight, all these tendencies are quite positive.

At first sight all outlined tendencies couldn't but give some acceptance.

However digitalization as a phenomenon of society development puts forward significant requirements [3] which digitalization will not be effective. These requirements imply that digital transformation should cover all the spheres including daily life. It also implied that the results should be used effectively and there should be free access for all potential users without any exception. Finally, it implied that users should have sustainable skills of dealing with digital information.

From this point of view the theory of digital transformation of education is of great interest. It was developed by Higher School of Economics [6] and presupposes solving specific tasks for higher schools. The theory is aimed at creating an innovative university model and digital university environment.

These ambitious tasks require great effort and financial investment But the success of solving any problems always depends on the willingness of students to accept these progressive changes and actively participate in the new educational process.

A short analysis of digitalization in education requires the discussion of its advantages mentioned by the authors such as increasing productivity indicators and education result, increasing student autonomy, saving resources, simplifying the process of education, increasing information accessibility and self-management in the information space, greater opportunities for communication in professional community all over the world. In other words, education digitalizing can transform a student from the object of educational influence into the subject of his own educational and training activities.

It is clear that digitalization has a number of weaknesses, difficulties and risks which should be considered in the organization of education process [3]. Authors usually mention such difficulties as the decreasing level of critical thinking and creative development, decline of mental activity due to the large amount of information and lack of time for critical understanding and processing of this information, narrowing the range of communication experience, human interaction and socializing.

Among the most important risks is a negative impact on health and and an increasing level of fatigue. Digitalization inevitably leads to total control of all the student activities and it has obvious risks. The most important risk is a review of pedagogical activities which are more and more turning into the coordination of the education process and consulting service for students. Teaching tends to gradually be replaced by digital technology and moderation is becoming the basic function for teachers.

These are the basic prospects for the development of the education system brought about by digitalization as well as the advantages and risks related to introduction of digitalization in education process. Now we should turn to the issue of the student readiness for digitalization processes which have started in many universities of Russia.

4 Problem of Psychological Readiness

The problem of readiness for any activity is one of the most important categories in psychology and is often considered to be a metacategory [9]. It represents all the psychological essence of a person: his interests, motivation, desires, knowledge, individualized assessment, emotional attitudes, and determination to fulfil any work. The category is related to a mental state of a person in situations concerning one's participation in this or that type of activity.

There are many opinions about this term in psychology. Researchers consider readiness as a suitability or unsuitability of the person for a certain type of work [10], and also it is regarded as an inclination for any activity posed by appropriate knowledge and skills [11]. Readiness is interpreted in several studies as a complex entity which includes motivation, orientation, operation, volition and value components [12]. It is also interpreted as a specific condition of subject transformation

influenced by professional, social, psychological and psycho-physiological factors [13].

In this article it is important to mention the research focused on the structure of readiness for professional work [14]. This structure is similar to the structure of readiness for education in digital form. This structure includes professional knowledge, perception about work, self-assessment for professional characteristics, understanding of professional education importance, satisfaction with universities education, commitment, autonomy and self-control.

5 Description of the Study

Understanding psychological readiness as a metacategory in the psychological system of knowledge [9] is an important key to correct survey conduction aimed at clarifying the level of student readiness for digitalization in education. The survey was conducted in two ways: by questioning the students and by analyzing their written works. 1st- and 2nd-year students of the State University of Management were interviewed. They study «Foreign language» as a university discipline at the undergraduate training courses. The questionnaires was written in English and included the questions about student attitude towards the on-line education in foreign languages, using modern digital technologies for the organization of education process. Besides, students were asked questions concerning their readiness for these changes and their opinion about the educational technology referred to as «Blended learning» [15, 16] as an alternative to total on-line education. Then the students were asked to prepare a written work (absolutely free in style) entitled: «Digitalization of foreign language acquisition: perspectives, difficulties and risks». All the works were analyzed and used as input for the development of the conceptual vision of foreign language teaching in the context of digitalization. So let us see and analyze all the results.

6 Results

The analysis of the results obtained allowed us to draw some conclusions. First, students have demonstrated sober and balanced treatment of all digital directions in education. They care more about particular aspects of modernization in education process such as using of on-line courses and their quality, perspectives of on-line access to training material, opportunity to have more free time out of university and work from home using PC or portable devices. Most students are perfectly aware that it is impossible to imagine the education in the XXI century without any modern technologies and without access to information and communication space.

Secondly, all the students interviewed realize the advantages of digitalization, informatization and computerization in education. They notice significant time

saving, opportunity to use new methods and technologies of foreign language acquisition , availability of a large number of authentic didactic materials (electronic textbooks, audio and video files, dictionaries, guides, journals). They emphasize such positive aspects as free choice of study guides and on-line courses, opportunity of communication with native speakers and users of language from all over the world, blurring of the time and spatial frameworks in education process, etc. And, also, students notice that there are more advantages than difficulties and problems.

Thirdly, fear of technological innovations, which is inherent in man, was among the difficulties mentioned by students, as well as technical difficulties and failures of internet performance, age difficulties which are related mostly to the teachers, technological backwardness of some regions, cities and educational institutions. Students also perfectly aware of the fact that modern technologies request a high degree of discipline in the organization of their own work, time management, choice of education trajectory, programs and courses, evaluation of their own achievements, managing education intensity and objective assessment of their results.

Fourthly, students realize all the potential risks which result from technological innovations. Especially they notice that due to explosive growth of information flow there is a great risk of getting unreliable, inaccurate and outdated information. The risk of misunderstanding between the partners grows during on-line communication. Students also mention a reduction of face-to-face interaction between people which can lead to loss of skills in interpersonal communication.

There is a risk to use a low-qualified service from teachers, choose low-quality courses or inconvenient educational platforms. And, finally, most of the students mentioned risk of negative impact on their health.

Fifthly, almost all the students claimed that they are ready for digitalization in education in spite of understanding all the difficulties and risks of digital revolution in education. But, they realize the specificity of foreign language acquisition and the fact that nothing can replace live interaction with teachers, not even high technologies. It is impossible to give up completely that kind of communication under the new conditions . Many of the students spoke about the importance of receiving feedback which they have in situation of live contact with teachers.

Sixth, all the problems raised by the students basically refer to the first aspect of digitalization, i.e. the creation of information resources of education process aimed at accumulating its content. They noted much less frequently the importance of developing telecommunication systems to provide communication processes in unified education space. The issues related to the organization and management of education process were not touch upon, which is not difficult to explain.

7 Conclusion and Recommendations

Summing up the analysis of digitalization in education process, the level and nature of psychological readiness of students for digitalization and the data obtained as a result of analyzing the written works of the students, it is possible to make some conclusions.

The first conclusion is that most students have subjective feelings of being psychologically prepared for digitalization of education process combined with sober and objective attitude to the opportunity of its implementation. The second conclusion is related to the specificity of foreign language as an academic discipline which deals the formation of verbal skills developed on a regular basis during practical studies under the teacher's control and with a feedback. The third conclusion is that transition to on-lone education in the area of foreign languages cannot be very quick, total and abrupt but should be implemented gradually. Education technology referred to as «Blended learning» is the most rational alternative to the total transfer of education to on-line system. This technology is based on a reasonable balance between on-line technologies and traditional methods of education [15, 16]. However most students have not heard anything about this technology.

On the basis of this research some recommendations for the preparation for digitalizing in education can be formulated.

1. Shape a platform for understanding the essence of digitalizing and its components emphasizing the importance of each of them for a student as an active independent participant of education process and the subject of his own educational and professional activity.
2. Make the transition process smooth and gradual, not total and rapid, make sure that transition has a reasonable time frame which is sufficient to develop all the psychological qualities required for digital education: autonomous style of work, self-regulation, reflection, self-control and self-evaluation. Develop motivation for learning, willingness to achieve better results of learning and focus on success.
3. Make extensive use of educational technology as a basis for learning foreign languages and create fertile ground for using progressive methods and teaching technologies such as project-based method, case studies technology, etc.
4. Maintain as much as possible humanitarian and humanistic missions of foreign language as an academic subject because it is a source of humanitarian knowledge, on the one hand, and a platform to train skills of interpersonal and intercultural communication, on the other hand.

Ecosystems in Personnel Management in the Digital Economy

Dmitry K. Zakharov, Ludmila V. Ivanovskaya, and Alina V. Pritoliuk

Abstract The formation and development of the ecosystem in the personnel management (HR-ecosystem) of the organization are discussed in the context of the active functioning of the digital economy. The concept of HR-ecosystem, goals, objectives and key elements of the system are investigated. The main attention is paid to the characteristics of goals, objectives and key elements of the system as applied to adaptation in the digital economy. The authors showed that the most striking example is ecosystems which formed and gained the development in large banking organizations in Russia. Organizations are forced to use the services of partner companies for the formation and development of the HR ecosystem enter into agreements with other companies in various fields of activity and create new subsidiaries within their organizational structure. The article shows the currently implemented and dynamically developing areas of ecosystem use. The article also discusses the concept of corporate health of employees as a necessary element of the organization's ecosystem. This term includes the formation of well-being, the development of conditions for communication, the creation of favorable conditions for the development of leisure and hobbies, the active functioning of the personnel training system, the inclusion of career management mechanisms for employees, and the provision of conditions to support the physical and mental health of employees of the organization. Personnel management mechanisms of various employment models are proposed: employees, freelancers, and gig workers.

1 Introduction

Ecosystem—a common concept that has several different definitions. For example, an ecosystem (ecological system) is a biological system consisting of a community of living organisms, their environment, a system of bonds that exchange matter and energy between them [1].

The ecosystem has many characteristics such as complexity, self-organization, self-regulation and self-development. The ecosystem is relatively closed and stable in time and space.

The term ecosystem applied in the economic sphere in 2016. The most striking examples are ecosystems formed and gaining development in large banking organizations in Russia. Customer requests are changing quite dynamically. Banks that occupy leading positions in their industry must respond to these changes in a timely manner in order to maintain competitive positions. The needs of bank customers have become more global. A service aimed at saving and partial multiplication of funds is necessary, of course, but it's so far from sufficient to maintain a leading and competitive position in the market.

2 Background and Methodology

The development of information technology greatly simplifies the process of providing and receiving various services, which are focused on the basis of a special platform for employees and customers of banks. Services such as cashback, mobile banking, and online banking have appeared in the recent past [2].

Huge Russian banks are constantly expanding and developing the capabilities of customers with the help of safe and relevant services. In this case, an ecosystem is a system of interaction between several service providers, regulators and consumers, which includes both competition and cooperation in order to provide a user with a particular service and accommodation [2].

A banking organization must handle to the services of partner banks, enter into agreements with other organizations of various fields of activity, and create new structural units within its managerial organizational structure in order to realize and develop the ecosystem's capabilities. Among currently implemented and dynamically developing existing areas, the following can be distinguished:

- Cloud technologies. A banking organization can organize a platform for creating cloud infrastructure with partner companies;
- Telephone and messenger services. This direction involves the organization and promotion of its own mobile communication service, which allows a business

organization to independently set tariffs, including connectors and various kinds of messages, as well as make extensive use of Internet traffic;
- Financial services. This type of service may involve the acquisition by the banking structure of the shares of financial companies and create on this basis a basic platform for managing electronic money;
- E-Health. This way includes the selection of high-quality medical services on favorable terms for the consumer as a possible element of the ecosystem;
- Life style. This is a relatively new, but actively promoted for domestic practice, direction of interaction with the client sector, aimed at analyzing its lifestyle and managing the culture of people's thinking;
- «B2C e-commerce», «B2B trading platforms», digital marketing. These possible elements of the system, which are used depending on the priorities of activities in various specific combinations, allow individuals and legal customers to purchase various types of goods in online stores;
- Cybersecurity and identification. These areas should, as a rule, be implemented by subsidiaries or other internal specialized units of the organization, due to the fact that they suggest the formation and development of large-scale projects for the protection of information, as well as functional and load testing of information systems of a banking organization.

In the near future, the formation and development of ecosystems can plan the development of many areas, for example:

- Rest and travel;
- Outsourcing of business processes;
- Distance and digital learning;
- Development of logistics chains [3].

The formation and development of the HR ecosystem in the organization is based on the fact that people aren't only the clients for the company, but they are also its personnel. As in society as a whole, the composition of employees in an organization is constantly changing [4].

At the same time, the organization must search, attract and retain workers of various types. In addition, it should involve them in the process of implementing their goals and motivate. Because of this staff is now also becoming a vibrant ecosystem.

Currently, the organization's dependence on contract, freelance and gig workers will sharply increase in the conditions of use and development of the digital economy. As the functional focus of the work is constantly expanding, it is economically feasible for organizations to hire independent contractors and sign contracts with freelancers. This category of workers is interested in faster work and receives payment upon delivery. Under these conditions, companies don't spend extra resources on finding and hiring employees and maintaining staff [5].

As alternative employment models are becoming more widespread, the personnel management services of organizations are forced to respond to these changes plan and create their ecosystems in personnel management. They will include the above

elements and ecosystem development directions in addition to the existing traditional tasks of the personnel management system [6].

Thus, the personnel management system is expanded and supplemented. This occurs using various models of employee employment. On the other hand, customers gain access to various categories of customers and clients. In addition, there are specialized units or subsidiaries that provide a wide range of services.

So, the traditional personnel management system is transformed into an HR ecosystem, including hired and gig workers, current managers and employees of the organization and service providers. It has greater flexibility than management system, capabilities and potential for managing human resources of studying various economic employment models, and searching for talents, which is especially relevant in the context of the development of the digital economy [7].

The attractiveness of hiring contractors, outsourcing technical work, and taking advantage of the emerging HR ecosystem entails a variety of problems that the organization must be prepared for. Therefore, the development goals of the HR ecosystem consist of: firstly, in the tactical search for a sufficient number of personnel of the right qualifications to carry out specified tasks at a specific time; secondly, in the formation of management mechanisms for employees of all employment models [8].

Workers in the new ecosystem have different perspectives, an understanding of the tasks to be solved, and a corporate culture. Currently, the management of freelancers and gig workers is carried out in a reactive mode, relatively unsystematic. The maximum that organizations do is tracking the implementation of contracts with these employees and the quality of their functioning.

In this regard, a row of problems in the personnel management of a modern organization can be formulated:

1. Crowdsourcing and outsourcing (external, involved to solve one or several tasks) employees don't know and aren't interested in the general development strategy of the organization. They need clear leadership, setting goals and objectives, and operational management more than other company employees. Only in this case, the work of such employees will be effective for the organization.
2. Tools and methods allowing the organization's management to manage crowdsourcing workers have been little developed and studied.
3. The availability of a complex problem of legal risks of the presence of such employees in the organization: they are associated with the possible disclosure of confidential information, security, and reputational risks [9].

3 Discussion and Results

The creation of an HR ecosystem is aimed at solving the indicated and similar problems of attracting workers using new employment models. It can be achieved as follows:

1. The personnel management service should closely interact with the legal service and information technology departments in order to develop specific performance indicators for outsourcing personnel. It's also necessary to organize initial corporate training and support for such employees in order for them to perform their functional duties effectively and consistent with the goals and objectives of the organization [10].
2. Human resources services should fully participate in the search and selection of outsourcing personnel. Currently, these functions are performed by those subdivisions that need to attract workers with alternative employment models. Because of this, there is practically no system of qualified selection for professional, personal and communicative qualities when outsourcing staff is involved. Qualified selection, as a rule, is replaced by an interview and filling out a standard questionnaire.
3. The company should organize further training and development for the "ecosystem" staff. Employers don't provide training and advanced training for outsourcing workers, because they think that it's an unnecessary expenditure of time and financial resources. In that case that the qualifications of such personnel ceases to suit the organization, employees are changed [11].
4. It is necessary to develop special incentive programs for workers of different employment models. It is also important to improve the system of employee motivation and incentives and show that the organization is interested in outsourcing staff to develop in the necessary directions, and the company is ready to provide him with all the opportunities for this development [12].

As the results, the development of functional responsibilities for the formation and development of the HR ecosystem can be proposed, which should be rationally distributed between the departments of the organization (Table 1).

It is important to include an additional support program aimed at ensuring corporate health of employees in the developed HR ecosystem in order to effectively manage the organization's staff and outsourcing employees [13].

Employee corporate health includes:

- Professional knowledge and skills that allow the employee to fully, efficiently and effectively perform their duties;
- Career opportunities, professional achievement, confession;
- Formation of employee well-being;
- Health status;
- Communication with colleagues and friends;
- Hobbies and creativity.

The development of an Employee Support Program (PPP) of various employment models may be proposed to ensure the corporate health of employees.

The ecosystem of large banking organizations in Russia, which was mentioned in the previous section, includes various services and attendances for bank customers. A dynamic HR ecosystem has to offer employees all the necessary list of services and programs that ensure their corporate health with the help of involved partners,

Table 1 Distribution of functional responsibilities for the formation and development of the HR ecosystem

Heads of services and departments, employees of the organization	Responsibilities for the formation and development of the HR ecosystem
1. HR Manager	Formation of a personnel management strategy using various employment models and outsourcing personnel. Interaction with the heads of other services and units that control the activities of such employees. A shift in emphasis in interaction with outsourcing personnel from fulfilling the tasks assigned to them to attract them to solve the problems of the organization, to increase the efficiency of their work, stimulation, evaluation and further training
2. CFO	Development of financial indicators of the effectiveness of outsourcing personnel, managing them as an extended resource of the organization. Assessing the relationship between the effectiveness of the organization and the efficiency of using workers of various employment models
3. IT Director	Collaboration with the personnel management service on the development and implementation of the information infrastructure for managing the HR ecosystem. Design of an information system for the management of services by the employee support program (PPP)
4. Chief Risk Officer	Development of a corporate responsibility program for employees of various employment models, including responsibility for the information and reputation security of the organization
5. Employees of the organization	Employees of the organization must timely respond to ongoing changes related to the performance of their functional duties, interact with outsourcing staff, clearly follow the newly developed organizational documents

agreements with other organizations of various areas of activity and new subsidiaries within its own organizational structure.

It is advisable to include in the composition of the teaching staff:

1. The development and operation of an information system that allows an employee to fill out an application and receive online advice on the necessary services;
2. Selection and further interaction with a personal consultant, based on information provided by the employee, in accordance with his wishes. The result of

interaction with a consultant can be either the provision of a attendances or the provision of a service, or a referral to a consultation with a narrower specialist;
3. Personal or remote consultations (at the choice of the employee) on psychological issues which are interested him;
4. Legal advice on labor law, real estate and others;
5. Financial consultations and consultations on services of various types of insurance;
6. Computer diagnostics and repair of home computers;
7. Marketing advice on the acquisition of goods and the provision of services;
8. Voluntary health insurance services;
9. Leisure services;
10. Providing travel packages.

An important point is the fact that the employee support program should be aimed at both full-time staff and employees with alternative employment models in the organization. It is appropriate that the companies offered as suppliers of goods and services be permanent partners of this organization. In this case, the mechanism for providing services and services is simplified in time and technically, and employees receive the desired services of the high and expected quality.

The following features can be considered as indicators of the effectiveness of the existing HR ecosystem in an organization [9]:

- Decrease in staff turnover (based on international experience, staff turnover is reduced by an average of 15% while introducing an HR ecosystem);
- Improvement in the ratio of income to expenses (by about 60%);
- Improving the quality characteristics of the organization's personnel (up to 80%);
- Increase the level of staff involvement in the organization (up to 75%).

4 Conclusion

To summarize all the text, it can be noted that the development of various models of staff employment in the organization is a new way of distributing functions, as well as a new type of relationship between the employer and employee, which is an integral element of the ecosystem. An important point for the current stage of development of the digital economy is the need to use the HR ecosystem in order for companies to fully get the opportunity of using the modern labor market.

The heads of the personnel management service and the organization have to actively interact with each other in the formation of the personnel management strategy and jointly develop a unified system for searching and selecting personnel with using various employment models.

Employment Promotion in Digital Format

Irina A. Strelnikova, Svetlana E. Titor, and Miroslav Jurásek

Abstract The Constitution of the Russian Federation guarantees labor and health protection, State protection from unemployment, a minimum wage and support for the disabled and elderly. Constitutional guarantees of protection against unemployment are implemented in Act No. 1032-1 of 19 April 1991 "On Employment in the Russian Federation" (hereinafter referred to as the Employment Act). By Protocol No. 16 of 24 December 2018, the Presidium of the Presidential Council for Strategic Development and National Projects has been approved and is currently implementing the National Project (Programs) "Labor Productivity and Employment Support". One of the objectives of the project was to improve the efficiency of the State Employment Services (hereinafter—SES), which are operative and active in order to prevent possible risks of unemployment and inefficient employment. The planned activities are aimed at modernizing and standardizing processes in the field of employment, updating and intensifying interaction between labor market participants: employers, employees, employment agencies, educational organizations and other participants. Informal forms of employment generated by information technology (distance work, remote work, etc.) broaden the horizons of the labor market for job seekers. This requires employment agencies in various constituent entities of the Russian Federation to adopt new approaches in their work. One of the solutions to these problems may be the creation of a service for the provision of public services, the performance of public functions in the field of employment promotion in the form of the Unified Integrated System of Employment Services (hereinafter—UIS).

1 Introduction

One of the state guarantees is the implementation of measures to promote employment. The promotion of employment means the provision of services by state authorities aimed at providing all forms of employment for citizens. These services are mainly provided at the regional level [1, 2].

A complete list of SES should be compiled on the basis of the list of powers of state authorities of the constituent entities of the Russian Federation in the employment sphere.

To implement the idea of forming the Unified Integrated System of Services Provision in the sphere of employment, it is necessary to analyze two aspects [3–5]:

- legal aspect: which services are to be included in the UIS;
- technical aspect: the capacity of existing information systems of employment services to create the UIS.

Among the existing public services should be included [6]:

- assistance to unemployed citizens in finding jobs and in selecting the right employees for employers;
- informing the population, government agencies and structures, employers and employees about the situation on the labor market in the constituent entities of the Russian Federation;
- organization of career fairs for employers or jobs for internships;
- in order to choose the sphere of possible employment, SES organizes professional orientation of citizens; if necessary, SES organizes and promotes professional training or professional development (retraining);
- unemployed citizens need psychological support, and SES organizes psychological support and their social adaptation to the labor market;
- unemployed citizens have the right to receive vocational training, including training organized in other areas;
- assistance to young people looking for a job in their spare time, aged 14–18 years;
- assistance in the employment and/or vocational training of unemployed young people aged 18–20 years, as well as graduates of vocational training organizations with a first-time job;
- SES keeps records of public works, where the unemployed can temporarily find paid work and they are provided with appropriate assistance;
- helping unemployed citizens in need of employment to find work in another area and supporting their relocation;
- the possibility for Russian employers to attract and use foreign workers;
- assistance and supervision in the employment of the disabled;
- organization of vocational training and professional education for people of pre-retirement age.

The procedure for the provision of public services is regulated by federal state standards and administrative regulations on the provision of public services adopted at the federal level.

No standards or regulations have been adopted [7]:

- on the organization of career fairs for employers and training workplaces for educational organizations;
- on the issue of the possibility of recruiting and using foreign workers.

Analysis of the legislation of the constituent entities of the Russian Federation showed that the following services are provided in a number of regions: Krasnodar Krai, Omsk Oblast, Primorsky Krai, Irkutsk Oblast, Ryazan Oblast, Kaliningrad Oblast, Sevastopol, etc.:

- notification registration of collective agreements;
- notification registration of regional, territorial, branch (interbranch) agreements;
- state examination of working conditions;
- provision of free legal support;
- resolution of collective labor disputes;
- support in facilitating the employment the disabled;
- increase in the mobility of labor resources;
- "Far East Hectare" program;
- facilitating the relocation of Old Believers to the Far East;
- social support for people with kidney failure;
- assistance to compatriots living abroad, including Old Believers, in their voluntary relocation to Russia;
- provision of employment support to soldiers dismissed from military service and their family members recognized as unemployed.

The existing information systems of the employment services of the constituent entities of the Russian Federation contain the following subsystems and modules:

Module "Work with citizens". This module provides an opportunity to automate the provision of services to citizens by employees of SES institutions. The module provides functionality and tools to provide citizens who have applied to the SES with a complete list of public services provided by federal and regional regulations in the field of employment, starting with the reception of a citizen, remote application of a citizen, document management in the provision of services, registration of citizens, independent search for work. For these purposes, the module includes several subsystems: "Reception of citizens", "Technological operations out of reception", "Order turnover", "Group technological operations out of reception", "Information about citizens (file cabinets)", "Information stall".

Module "Interaction with organizations" automates the work of the SES specialists to provide public services to employers: collection of vacancies, information on the personnel composition, the release, training of employees from employers, the employment of foreign residents. The module provides selection of job applicants to fill vacancies. The module includes several subsystems that ensure their operation [8]:

– working with an organization;
– receiving information from the organization;
– need for employees;
– contracts;
– events;
– training groups;
– information on attraction of foreign labor force.

Module "Accrual and disbursement" automates the work of the SES staff in calculating, producing statements and other documents related to disbursements and withholdings.

Using the "Reporting" module, the preparation of reports in the appropriate forms is automated; the logical integrity of all reporting data is monitored; and the timeliness of reporting is monitored. Reports are generated in the following subsystems:

– calculation of forms of state statistical reporting;
– departmental reporting;
– regional reporting.

In order to keep the general data on different servers of the system up to date, automate the settings, maintenance and monitoring of the Program complex, the settings of templates and forms necessary for the use of the complex [9], the processing of primary data, as a result of which they are prepared to work in OLAP-technology, the formation of OLAP-cube, where each cube is separately set the modes of processing its tables, the system has several technical modules:

– application data replication;
– administration;
– information packages upload;
– conversion of uploaded data;
– formation of OLAP-cubes;
– creation of analytical tables.

Part of OLAP Services is based on MS Excel, where the mechanism of free tables is integrated to work with OPAL Services storages [10]. The analytical capabilities of the system determine the range of modification and presentation of information in two-dimensional and multidimensional tables, computation and data classification tools [11, 12].

The existing system of collection and processing of information on employment is based on the unidirectional collection and consolidation of registers of recipients of public services in the field of employment in the information system of the Federal Labor and Employment Service (hereinafter referred to as Rostrud), starting with SES institutions and ending with Rostrud.

The order of information exchange is regulated by the order of the Ministry of Health and Social Development of the Russian Federation from November 8, 2010 No. 972n "On the procedure of keeping the registers of recipients of state services in

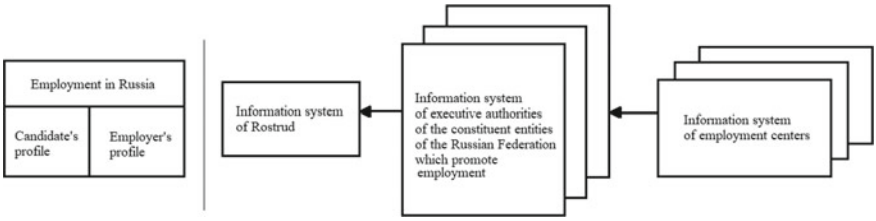

Fig. 1 Employment information collection and processing system

the sphere of employment of the population (individuals and employers), including the procedure, term and form of submitting information in them" [13].

At this, today, this system allows to exchange information with the portal "Work in Russia" only in manual mode (Fig. 1).

1.1 Methodology

Employment issues are well studied in legal and social literature. The digital transformation of employment services is a completely new phenomenon. The new scientific views of this work are based on research in both the legal and social spheres, as well as in the digital economy: Matveeva, P. A. Peculiarities of employment: through the prism of transformation and crises: monograph/P. A. Matveeva, V. V. Matveev. Chelyabinsk: Biblioteka Millera, 2019; Digitalization of industries in the Russian economy: monograph/Abdullaev, N. V.; Avanesyan, N. V.; Artyukova, A. V. et al./Under general editorship of Doctor of Economics, Professor I. B. Teslenko. Vladimir State University, Moscow: Rusains, 2019; and others. Theoretical and practical provisions of the article are devoted to the study of optimization of employment promotion issues in the modern digital economy. General scientific and private-scientific methods of research, including dialectical, formal and logical ones, are applied, as well as the method of analysis and synthesis and the method of modeling.

2 Results

The analysis of public services in the field of employment promotion for digitalization of services made it possible to classify them as centralized and unique.

Centralized services should include State Employment Services provided by the services of the constituent entities of the Russian Federation under the current Employment Act, as well as those services that cover the population without reference to regional location.

For example, the Employment Act does not provide for such services as the organization of vocational training and additional vocational education, professional

retraining of people of pre-retirement age. Nevertheless, such a service is provided by all regions everywhere, which gives it the right to be considered centralized [14].

Unique services should include services in the field of employment promotion, which are provided on the basis of legislation of the constituent entities of the Russian Federation. Unique services are, as a rule, of a single nature, provided in one or several constituent entities of the Russian Federation, but at the same time they are of a nationwide nature and significance [15].

However, an analysis of public services shows that most of them do not relate to the powers of employment centers as defined in the law, but to other areas of legal regulation and public administration, therefore their inclusion in the Unified Integrated System of Employment Services seems inappropriate.

At this, some public services, which are provided by individual regions on the basis of their specificities, but which are of a national nature, should be included in the UIS. Such as, for example:

– assistance to compatriots living abroad, including Old Believers, in their voluntary relocation to Russia;
– providing employment support to servicemen dismissed from military service and their family members recognized as unemployed.

Changes to the existing format of information exchange organization among the UIS operator, employment agencies of the Russian Federation subjects and other authorities and organizations, including the frequency of information exchange, methods and formats of interaction, should consist of two components:

– change in the legal framework;
– technical changes.

Basic principles of changing the legal framework:

– legislatively, the terms of information exchange are changed, the term becomes "online". It is necessary to make appropriate changes to the Order of the Ministry of Health and Social Development of the Russian Federation of November 8, 2010 No. 972n "On the order of keeping the registers of recipients of public services in the field of employment (individuals and employers), including the order, time and form of presentation of information in them" [13];
– the electronic format of the document circulation is legally established;
– the possibility of providing employment services in electronic format is legally established;
– the use of the UIS in the provision of employment services is legally established;
– the terms and procedure for exchanging information with other authorities and organizations, including the frequency of information exchange, methods and formats of interaction, are defined in Sect. 1.3 of this report (participants in the formation and filling of the register of employment services of the constituent entities of the Russian Federation).

As technical changes it is proposed to modify the existing system of information interaction in such a way that it is bilateral, i.e. information is not only collected

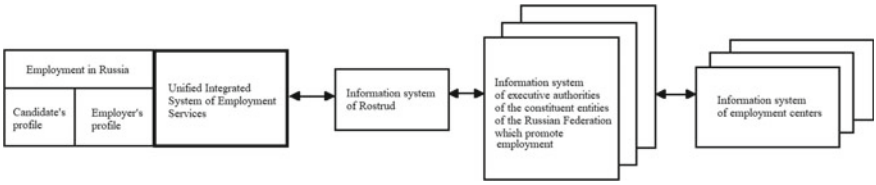

Fig. 2 Proposed organization of the system for collection and processing of information on employment of citizens

and consolidated in the information system of Rostrud, but also distributed in the opposite direction to the level of employment centers information systems. This process should be done automatically online. To this end, it is necessary to create the Unified Integrated System of Employment Services (referred to as UIS). It is also proposed to integrate the UIS with the portal "Work in Russia" and ensure its automatic interaction with the information systems of Rostrud (Fig. 2).

2.1 Conclusion/Recommendations

The Unified Integrated System of Employment Services should be based on existing information systems, have the same functional qualities, meet the same functional requirements, except for two innovations:

– it should be based on "Work in Russia" portal;
– online information transfer and feedback are organized by technical and legal methods.

The study of the legal and regulatory framework governing employment promotion within the framework of the study—the creation and transition to the Unified Integrated System of Employment Services—highlighted the following areas of change:

1. Formation and filling of a unified centralized register of employment centers' services in electronic format;
2. Updating the standards of employment services through their conversion into electronic format.
3. Development of necessary (missing) state regulations for provision of state services in the sphere of employment.
4. Transition to the digital format of relations between the Federal Labor and Employment Service and other executive authorities in the area of employment services.

The Human Capital and Labor Market in Digital Conditions: Peculiarities of Interaction and Possibilities of Its State Regulation

Asror A. Urunov, Zarrina B. Akramova, and Shohzodakhon M. Naziri

Abstract The article describes the features of human capital formation and its interaction with the labor market in the conditions of digitalization on the example of Sughd Region of the Republic of Tajikistan. The purpose of the article is theoretical grounding of peculiarities of human capital formation and its realization on the labor market as a factor of region growth. The methodological base of the research includes system and graphical-analytic methods of analysis, the use of which will allow to approach scientifically grounded development of recommendations on effective realization of human capital potential on the labor market of the region with the purpose of ensuring full employment. Trends in the development of the regional labor market and structural changes in the composition of the labor force are analyzed, and a detailed analysis of the components of the human development index in Sughd is made, which reflects the processes taking place and determines their dynamic and structural characteristics. The dynamics of expenditures of the region's budget on human capital development is studied. It has been proved that the misalignment in economic policy leads to a structural mismatch between demand and supply in the system of training and employment of qualified personnel, which has a negative impact on the final indicators of the regional economy. The results of the research can serve as a basis for developing strategic plans for regional development and state regulation of the country's labor market.

1 Introduction

With the transformation of social, political and socio-economic life in Tajikistan, significant changes have taken place in such key areas as: the national economic management system, the institution of property rights, the institutional role of the state in regulating the labor market, etc. The problems under study are discussed in the works of domestic and foreign scientists, such as E. Yanzhul, W. Petty, F. Quesnay, S. Sismondi, A. Baranov, V. Basov, V. Gimpelson, T. Gorbacheva, V. Goylo, E. Gvozdeva, A. Dobrynin, A. Lukyanova, V. Martsinkevich, R. Kapeliushnikov, S. G. Strumilin, M. Sonin, I. Soboleva, I. Tulchinskiy, T. Shtertser, I. Kharchenko, E. Tsyrenova, etc. They have studied various aspects of the problem of formation and development of human capital and labor market as key factors of growth in the conditions of digitalization of economy [1–4].

Features of the digitalization of the economy, due to the complication of the interaction of technological, social and economic processes, provide for the study of the phenomenon of full employment in the perspective of interaction with training and retraining of personnel with the labor market, the importance of which in modern conditions is increasing sharply at all levels, including the inter-country and national levels, the level of regions, industries and firms.

The purpose of the article is theoretical substantiation of the peculiarities of formation of human capital taking into account the requirements of the labor market and development of practical recommendations for their effective interaction in conditions of digitalization of economy on the materials of Sughd Region of the Republic of Tajikistan, the population of which is more than 3 million people. In this manpower-surplus region, the problem of organizing a perfect labor market model is one of the urgent tasks.

The problems of human capital formation and its regulation in the conditions of digitalization, including the widespread use of artificial intelligence, robotics and their social consequences, have not been fully studied and are now one of the actual areas of research. Scientists predict that if the above innovations are successfully used in the labor market, the world is expected to increase unemployment from its natural level to 30%. It is proposed to improve legislation on the organization and management of unemployment benefit payments [5]. For the Republic of Tajikistan, this may be the number one problem, since the region is manpower-surplus and currently, according to various estimates, the unemployment rate is between 10 and 15% [6].

2 Methodology

The methodological base consists of system-complex and deterministic approaches, economic and mathematical methods, as well as graphical-analytic methods of

research. To reveal interrelation of factors the regression method of analysis is applied.

3 Results

Analysis of the structure of formation and development of human capital in the context of digitalization of the region's economy is characterized by quantitative and qualitative features, which act as labor potential and human capital. The impact of human capital on gross regional product (GRP) is undoubtedly great. By means of regression analysis on the basis of statistical data for 2009–2018, the authors assessed the contribution of physical and human capital to GRP, the model of which can be described as follows [7]:

$$GDP = 205.3569 + 4270.3645\ Ihc + 20.7521\ Imc,$$

where *GDP* is thousand somoni; *Imc* is the main capital investments, thousand somoni; *Ihc* is investments in human capital, thousand somoni. At the moment of evaluation, $1 amounts to 9.82 som oni, or 1 somoni amounts to $0.1018.

Human capital is understood to mean the totality of all productive qualities of an employee, i.e. this concept includes acquisition of knowledge, skills, as well as motivation and energy used to produce economic benefits. In order to assess human capital development in Tajikistan and Sughd Region, an analysis of Human Development Index (HDI) components was carried out, which will more accurately reflect the ongoing processes and reveal their dynamic and structural characteristics (Table 1). Despite the high potential of human capital in the region, there is still insufficient investment, which hampers its development and is a very urgent problem. As the data of Table 1 show, over 10 years (2009–2018) the Republic of Tajikistan has hardly changed its position in the Human Development Index rating.

Low efficiency and quality of education, low level of medical and social services, low income, high rate of unemployment and migration outflow of population reduce the quality of human capital in Sughd Region and the country as a whole, as evidenced by the country's ranking—125th out of 187 countries with HDI value of 0.656. For comparison, Russia takes the 49th place (0.824), Kazakhstan takes the 50th place (0.817) [8]. In this connection, the dynamics of Sughd Region budget expenditures on human capital development was analyzed (Table 2).

The results of the survey show that the share of public investment in human capital development in the structure of GRP of Sughd Region in 2018 was 7%, and in the dynamics of 10 years it increased only by 4.66%. For comparison, public investment to improve the quality of human capital in developed countries accounts for 10–12% of GDP. This is explained by the fact that budget revenues have not yet reached the optimal value, as the economy is weak and the taxable base is low, and, accordingly, the share of budget expenditures on education and health care gives us a distorted value. For example, per capita investment in human capital in the region amounts

Source Authors' calculations, according to data [6]

to 444.59 somoni or $45. At the same time, the developed world is spending 15-25 times more. In Kazakhstan this investment is over $900, while in Russia it is $470 [5]. Studies show that a 1% increase in government spending on human capital development contributes to a 1.19% increase in GRP in Sughd. This fact confirms that this factor is a growth driver for the region's economy.

The functioning of the labor and education market in the region has a number of features, being an important part of a complex socioeconomic system. Interaction with each other is aimed at meeting the demand for educational services from consumers and the demand for highly qualified personnel from employers.

Analysis of the situation in the regional economy requires a systematic study of the phenomenon of unemployment, the level of which is an important indirect indicator of the labor market. Table 3 presents the structure of the unemployed population by age groups and education level.

As it can be seen from the data of Table 3, the unemployment rate among the population under 18 years of age tended to grow until 2013, and starting from 2014 this indicator began to decrease. This is due to the fact that the share of graduates of general education institutions wishing to obtain higher and secondary vocational education has started to grow. From 2009 to 2013, unemployment rose from 6 to 8.4%, while from 2013 to 2018, on the contrary, it fell by 3.3% (from 8.4 to 5.1). Among the population aged 25–29 years, unemployment has the highest rate. Unemployment among the pre-retirement age population has a small share. In our opinion, this is due to the fact that at this age, the applicant for vacant jobs is already retraining or adapting to the labor market conditions. The increase in the number of unemployed is especially noticeable among young people aged 18–24 years, the growth from 25% (2013) increased to 33% (2018). This is the age at which young people actually enter the labor market after graduation. The increase in the number of unemployed people is due to the fact that not all graduates of educational institutions can find a job at the desired salary.

Despite the obvious fact that one of the main factors determining an employee's position on the labor market is his or her level of education and that the greater the stock of accumulated human capital, the lower the risk of joining the ranks of the unemployed, unemployment among the educated population is growing in the region

and its size makes up a significant share. This is due to many factors: with the period of professional development of young professionals, and it is extended by years, they often change jobs, seeking a more prestigious and highly paid job. Of course, not all graduates look for work and enter the national labor market. For example, some of them plan to continue their education or immigrate to other countries such as Russia, USA, Canada, China and South Korea, etc.

Of the total population, the increase in the number of unemployed among those with a college degree is alarming. On average, its number is about 1000 people, and in the dynamics, if we compare these figures with the actual number of graduates of universities, we find that it tends to grow. Thus, at the beginning of 2018 the share of unemployed with a college degree was 15.2% of the total number of university graduates, in 2013—13.4%. This shows that graduates entering the labor market do not find a job in their specialty in the medium term. Unfortunately, the growth in the number of unemployed in this category creates serious obstacles to the realization of the potential for sustainable economic growth. By the way, this category is dominated by the ability to develop innovative ideas and projects that are necessary for the modern economy of the region.

At present, the number of vacancies in Sughd Region is 4 times less than the demand for it (Fig. 1).

That is, there is an imbalance between supply and demand in qualitative and quantitative terms. In this connection, to characterize employment we also analyze the structure of the number of employed in the economy by forms of ownership (Fig. 2).

The market reforms carried out in the country bring structural changes in the composition of the employed in the economy by form of ownership. The vast majority is occupied by private property, almost 50%, which is 3 times more than the number of employees in the public sector.

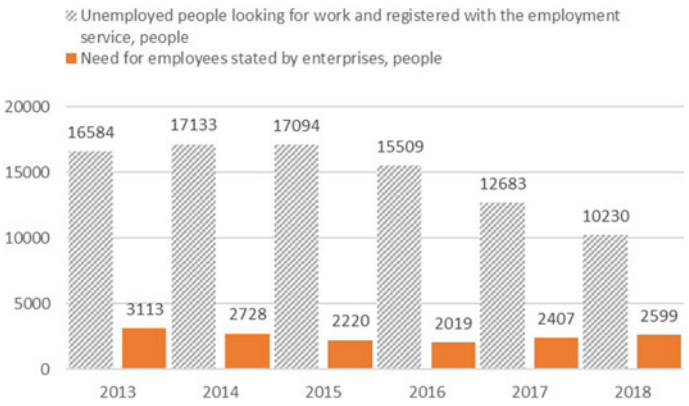

Fig. 1 Dynamics of the number of unemployed citizens and vacancies registered with the labor and employment authority, people. *Source* Compiled by the authors by source [6]

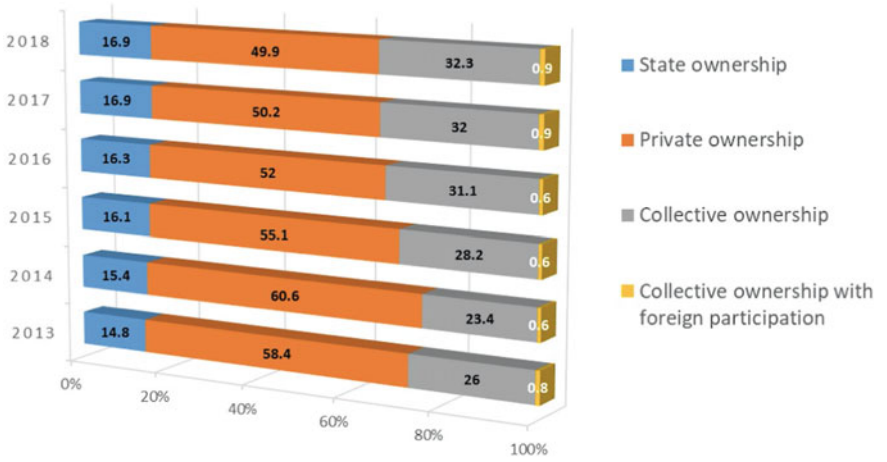

Fig. 2 Structure of the number of employed in the economy by types of ownership in 2013–2018 (% of total volume). *Source* Compiled by the authors according to data [6]

As a result of the increasing share of private ownership in the labor market, employers are placing a higher demand on the skills and knowledge of hired staff. On the one hand, this is positive, which increases competition and, on the other hand, provokes the temptation to exploit workers with lower wages. For example, the average salary in the region is 1,072.6 somoni, equivalent to $110, with a commodity bundle for a family of three exceeding $135 [6].

Thus, the analysis of the labor market shows that the region, with its huge potential of labor resources, cannot use them effectively for the sake of economic growth, as evidenced by the low standard of living and quality of life, high unemployment rate, growing migration processes in the country and the number of economically inactive population.

In the future, the most important component of the development of the digital economy is the creation of a technological platform, which represents a key organizational innovation in the formation of human capital and its realization on the labor market. Technological platforms provide interaction of the state, business and higher education institutions around a common vision of breakthrough technologies. They are a new tool for forming the innovation infrastructure of the labor market. Technological platforms bring together stakeholders in identifying and addressing the long-term challenges of balancing supply and demand for labor, which in turn requires an adequate mechanism of government regulation in this area. In this connection, the latter should take into account, firstly, economic specifics of the given market and region; secondly, peculiarities of its formation in the regional economy; and, thirdly, positive experience of regulation of market systems in developed countries.

The digital economy has clear advantages in terms of reducing the cost of producing and selling goods and opens up new income opportunities. Moreover, online services are mostly cheaper than in the traditional economy (primarily due to

lower promotion costs), and the services themselves, both public and commercial, are more affordable. In addition, services such as labor supply, demand for labor in the digital world can quickly enter the global market and become available to employers anywhere in the world. The product offered can be customized almost instantly to meet new expectations or consumer needs. In the light of the above, the technology platform will provide online, constantly changing job postings for all occupations in employment centers and in the mobile application of personal gadgets.

In general, the orientation of government policy in Tajikistan at this stage should be aimed at creating a modern digital technology, the so-called digitalization of the labor market, which has such properties as: a high degree of self-organization based on dynamic homeostasis; co-evolution, which ensures mutual development in the interaction of interested organizations; emergence-integrity, if there are properties of the system that are not inherent in its elements. The efficiency and quality of such a structural unit will be determined, first and foremost, by human capital and the harmonious development of the labor market.

4 Conclusion

We should note the novelty and practical recommendations of the study.

1. It has been established that the existing socio-economic problems and their solutions in Tajikistan do not ensure sustainable growth and the effective use and preservation of human capital in the region. Despite the high potential of human capital, there is still insufficient investment ($45 per person), which constrains its development and is a very urgent concern. Studies show that a 1% increase in government expenditures on human capital development contributes 1.19% to GRP growth in Sughd Region. This proves that this factor is a driver of economic growth in the region.
2. Despite the obvious fact that one of the main factors determining the position of an employee on the labor market is his or her level of education, there is an increase in the number of unemployed among residents with a college degree. From 2013 to 2018, the share of the unemployed with higher education increased from 13.4 to 15.2% of the total number of university graduates, which indicates that graduates, entering the labor market, do not find work in the profession. Unfortunately, the growth in the number of unemployed in this category creates serious obstacles to realizing the potential for sustainable economic growth. As a result of the increasing share of private ownership in the labor market, employers are placing high demands on the skills and knowledge of the workforce, tempting them to exploit their employees for little pay. The average salary in the region is $110, with a commodity bundle for a family of three exceeding $135.
3. It has been established that the current situation on the labor market in the region in the conditions of the digitalization of the economy does not meet the modern requirements, there is not enough effective mechanism of interaction between

universities and employers regarding the rational use of human capital potential. In the future, the most important component of the development of the digital economy is the creation of a technological platform, which represents a key organizational innovation in the formation of human capital and its realization on the labor market. Technological platforms ensure effective interaction of the state, business and universities around a common problem. On the basis of the technological platform, constantly changing job postings will be provided online for all occupations in employment centers and in the mobile application of personal gadgets.

Marketing Strategies of the Company Development within the Transition to a Digital Economy

Igor V. Semenov

Abstract *Purpose* The purpose of the article is to present a strategic marketing approach to crafting marketing strategies of the company development (MSCD) in an emerging digital environment. *Methodology* Based on the sources of academic research on the information revolution, the author highlights a set of strategic rules for the MSCD using the adapted Rogers's model of the digital transformation; investigates the possibility of overcoming previously identified the methodological contradictions of strategic marketing in relation to the requirements of the digital market; and clarifies the terminology in the field of business digitalization (BD) taking into account differencies of the two market-oriented behavioral models and the typology of value creation system (VCS). *Findings* From the standpoint of modern strategic marketing and in view of earlier author's research findings: 1. A change in the CEO's point of view from the positioning the company in the industry to the developing VCS as a starting point for initializing the process of BD is proposed. 2. The boundaries of the strategic continuum of BD are set. 3. The model of the digital MSCD is proposed, considered in view of the scale of BD and differences in VCS. *Conclusions* The digital economy enhances the role and importance of an organizational strategy. The information revolution is waiting for new systemic and cultural challenges for the BD. MSCD have become the object of modelling the market-oriented behavior of customer ecosystem actors and a tool for configuration and recombination of value flows in "constellations" at the macro, meso, and micro levels of the digital economy.

1 Introduction

It has already become an axiom that the success of a company in a market economy comes from obeying its laws and rules. However, the implementation of this demand is a bunch of unknowns. In the 1970s there has been a break in the development of the world economic community: the industrial-technocratic era has been replaced by the information-knowledge era. Today, this break is characterized by a phase transition to a digital economy and is accompanied by an exponentially growing uncertainty and unpredictability of its market environment. The "old" economy, or the economy of supply, developed according to a linear scenario due to the industries of material production. It was organized on the principle of "long-linked" chains of enterprises from the production and processing of raw materials to manufacturing of finished goods. All enterprises of one "link" could not "go beyond" of their chain, since market rules and technological standards preclude this possibility. Industrial giants acted as the "locomotives" of growth and raced along the "rails" of their chain, rapidly gaining momentum through "economies of scale", and therefore marketing strategies were programmed to maximize sales. Today, this strategic logic no longer determines market success. The information revolution removes "chain" barriers. The main source of economic development is the inherently tacit, in-depth knowledge of market participants, as representatives of various industries, in the development of multi-sides platforms and networking. And the main asset is their ability, as actors of the market ecosystem, to interact with each other in the process of creating customer value. This reflects the networked nature of the "new" economy of demand. A radical change in market rules forces business leaders to focus on the challenges of achieving the best compliance with these rules through the marketing strategy of the company development in the digital economy.

The purpose of the article is to present a strategic marketing approach to crafting marketing strategies of a company development in an emerging digital environment.

2 Background and Methodology

Like the introduction of electricity in the industrial environment since the second half of the nineteenth century has brought breakthrough changes in the manufacturing industry, the cross-cutting penetration of digital information technologies into business processes entails a similar wide-scale impact on the strategic rules of enterprises' performance in a virtual environment [1]. The end of the 1970s, when the world economy shifted from the old industrial-technocratic to the new information-knowledge models, is commonly believed a cut-off point.

We can present the results of the review concerning the new strategic rules dictated by the information revolution by five domains (customers, competition, data, innovation, and value) of Rogers' digital transformation [2]:

(1) Customers: using connectivity for transition from a mass market to a dynamic network. Since consumers are no longer isolated from each other due to the widespread use of the Internet, digital technologies allow them to integrate into dynamic network structures. The "sales funnel" principle gives way to the "consumer journey" model 2, which involves fixing the "contact points" with the brand in a virtual space and moving from one-way communication to multi-sided and multi-channel interactions in the client network. And by studying the customer experience, the brand owner makes corrective actions in the marketing strategy [3]. Thus, digital technologies offer new methods not only for communicating with consumers, but also for co-creating value with them [2, 4].

(2) Competition: using the digital technologies to build a platform development strategy. The digital environment erodes the boundaries between industries and generates asymmetric competition as a result of "disintermediation," that is, breaking and redistributing relationships among partners within and outside the value chain [2]. On the other hand, this environment creates incentives for direct competitors to collaborate [4]. The main priority is to develop digital business models that increase the total flows of consumer value through networking. The importance of business strategies aimed at building platforms, not just product development, has increased dramatically. A platform is a way of connect participants of two or more multi-sided markets that enabling to provide value-creating interactions between external producers and consumers. It sets the rules for the marketplace in which producers and consumers meet. In its basic structure, the platform consists from four types of players: owners, providers, producers and consumers [5]. Creating a platform is becoming the main source of competitive advantage, as allows players joining into a single ecosystem to co-create value and achieve a synergy between the volume of information and network interaction [4]. The main assets are the community and the resources of its members, and internal processes of resource optimization give way to the coordination of external interactions. As the ecosystem expands, the average value of each transaction and the total value generated by all its actors increase due to the "network effect", which is central to this strategy [5, 6]. The focus of the strategy is shifting from the tasks of ensuring strict control over resources to finding the best ways to orchestrate them.

(3) Data: using the digital technologies to turn data into strategic assets. Each marketing student is aware of the importance of distinguishing between data and information essential for management decisions [7]. But the digital revolution has made this rule available to the entire business community. Most of the data is generated as a result of many random events, including conversations and

other forms of communication, within and outside the company. Earlier expensive and powerful IT systems have been required for data storage. Now data analysis is equally accessible for each market participant, from an ordinary employee of the company to its consumer. Users of social networks and mobile devices generate a huge stream of unstructured data. However, cheap and easy-to-use cloud storage systems are available around the clock, and specialized web analytics services, such as Google Analytics and Yandex.Direct, allow anyone who wants to, after appropriate training, to extract useful market information from the data. It has become clear that the enormous bulk of data in the digital environment that are most often free and redundant, are not useful by itself. It is important to translate them into a strategic asset, i.e. extract meaningful information and use it to generate new value [2]. The new market rule should also include "data democratization" concerning the dissemination of digital products, services, and technologies. This is economies of scale on the demind side, or "winner-take-all markets", which is obtained not from producers themselves, as in the industrial economy, but from buyers, as far as the digital market offers become available to an unlimited number of users due to low replication costs [6].

(4) Innovation: using the digital technologies to innovate on the principle of openness. Personal knowledge is tacit by its nature [8], i.e. must be codified and transmitted through direct communications. The knowledge diffusion process is a "socially spatial" phenomenon, e.g. it is passed informally through face-to-face contacts. The digital economy provides a continuous exchange of consumer value information between members of the widened innovation process, i.e. beyond individual companies and industries. This process leads to the development of new generations of digital technologies, products, and services for consumers, as well as never-seen markets and niches, including for "old" offers. The transition from a "closed" innovation process to the paradigm of "open" innovations acts as a new strategic rule [9]. In the industrial economy, an innovative process was "closed" inside of the company, i.e. organized according to hierarchical type with a monopoly on any internal novelty, since its generators were employees of the company's R&D departments. Now the performance of digital innovators depends on the involvement of both internal and external sources of innovation since their generators are often outside the company. Useful knowledge becomes "open" and can be widely disseminated to a very large extent through personal contacts on social network. Commercialization of innovations occurs due to the free dissemination of knowledge between all interested participants in the "social innovation network" within the market process. This "open" model saves time, reduces the risks of unpredictable decisions and the time spent on eliminating their consequences, as well as helps to gather advanced innovative experience. Digital tech-

nologies have considerably speed up, cheapened and facilitated the stages of the entire innovation process. Product versions succeed at an unprecedented speed, as it became possible to get customers' feedback and use them as co-creators of new personalized market offers [4]. Continuous "open" experimentation with both convergent (testing previously advanced hypotheses) and divergent (lack of formalization at the initial stages) methods allows testing concepts and creating prototypes almost for free, because user communities want to participate [2]. Thus, in view of the effect of blurred borderlines between industries, the focus of innovators is shifting to the establishment of innovative space for the continuous generation and distribution of consumer value.

(5) Value: using the value creation system as a starting point for the development of a business digitalization strategy (Fig. 1).

In each of the above strategic domains, the core process is the generation of consumer value as a result of the interaction between all actors of the market process. M. Porter was the first to emphasize the need to arrange such an interaction in the mid-1980s within the "chain value system" model typical for an industrial economy [10]. However, the excessive focus of the management of industrial giants on solving the problems of internal efficiency (spending of limited resources and streamlining of production) did not allow them to recognize the primary role of the consumer who did not have a "vote" [11, 12]. At the turn of the 1990s, under the influence of the information revolution, an alternative technology, or the "network" model of relationships between market participants, has been developed, in which the consumer acts as leading actor

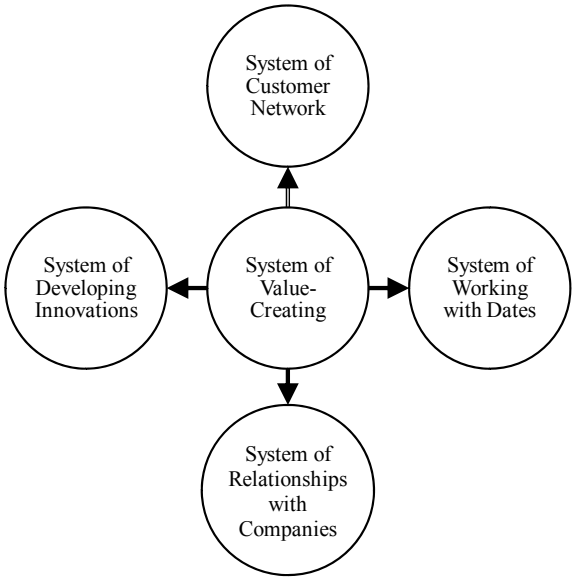

Fig. 1 Adapted model "five domains of digital transformation"

in the "value-creating system" [13–16]. Today, this principle is embodied in strategic marketing as a concept of the customer ecosystem of the market [17].

Thus, the information revolution and the advent of new digital technologies have established new strategic rules for companies on the way of business digitalization (hereinafter referred to as "BD"). As can be seen from Fig. 1, the development and delivery of a value proposition for a market entity depend on its role in the value creation system (hereinafter referred to as "VCS"). This circumstance is of critical importance for the formation of digital marketing strategy of the company development (hereinafter reffered to as "MSCD").

3 Discussion and Findings

At the turn of two millennia, a crisis has occurred in marketing management theory, when business demands fall outside approaches and methodological tools developed during the heyday of the industrial era. The researchers more and more pointed out that the operational issues are increasingly solved by marketing departments to the detriment of the strategic objectives of the entire company aimed at consumer value [17–20].

A series of our earlier studies have allowed us to make an assumption that in the concept-mainstream works their authors do not take into account the specific features of knowledge economy [11, 12]. After a comparative analysis of the differences between the chain and network VCS, we revealed three methodological contradictions between (1) the analytical and cultural dimensions of strategic marketing; (2) a narrow-function interpretation and the scope of the marketing strategy, and (3) reactive and proactive types of market orientation. Ultimately, we have concluded that "identified contradictions cannot be overcome within the industrial-technocratic paradigm of a market economy performance" [11, 12, p. 96].

The above stated allows us to argue that the transition to the digital economy helps remove three methodological contradictions:

(1) strategic marketing is redefined from the standpoint of market-oriented thinking. As noted above, the new strategic rules force the company's management to expand their understanding of the scope and boundaries of products, technologies, and industries. Strategic marketing can be considered as "a market knowledge platform" for making decisions about the configuration of value flows at the micro-, meso- and macro-levels in an unlimited number of customer ecosystems. In our opinion, the success of BD to a large extent hinges on whether the company's management distinguishes between VCS of chain and network market models. Knowing the differences, the management can not only predict the nature, scale, and duration of upcoming changes but also (that's more critical) to ensure the integrity of the company's transition to a qualitatively new digital state [11, 21].

(2) the narrowly functional view of MSCD causes the loss of strategic competitiveness by the company. In the industrial-technocratic paradigm, the marketing strategy was defined as "the basic approach that the business unit will use to achieve its objectives, and it consists of broad decisions on target markets, marketing positioning and mix, and marketing expenditure levels" [7, p. 287] and, therefore, its scope of application did not extend to the corporate level [10, 12, 16, 18, 22], which addresses issues of generating consumer value for the entire company.
The new strategic rules lay the foundation for the interpretation of marketing strategy as the main proactive tool, i.e. predicting market opportunities, or opening "strategic windows" for the company. MSCD interconnect "the set of market-oriented strategic actions of the entire company at the corporate, business-unit and product-line (product brand) levels to satisfy its customers and thereby enable it to gain a long-term competitive advantage through by providing the highest consumer value" [11, 12, p. 97]. Within the transition to a digital economy, MSCD turns into leverage for the creation of a chain-network space of consumer value at the macro-, meso- and micro- levels of the market ecosystem.

(3) a simultaneous combination of reactive and proactive types of market behavior of the company is achieved due to the synthesis of business units from different VCS (both chain and network). The scale of changes in the company caused by the need for BD depends on the leadership attitudes [1917]. Strategic intentions must be stated with regard to the digitalization capabilities of both the company and the entire consumer ecosystem of the market. Along with that, the digital MSCD should be coordinated with the general strategy of the company in the physical space in avoidance of cannibalization of existing business units. It should also be borne in mind that the opportunities of online business can go beyond offline market space, as far as in the digital economy, the consumer ecosystem assumes pushing the limits of material industries and bringing together earlier incompatible products, services, and technologies.

By virtue of the chain-network synthesis of offline and online value flows, one can craft brand-new business models and use them to change the established patterns of consumer's purchasing behavior at various stages of the life cycle of products, technologies, and industries. Besides, it is necessary to regard the hierarchy of the company's strategic goals from three levels of the marketing strategy pyramid within the company [corporate, business unit and product line (product brand)] to the macro-, meso- and micro-levels of the consumer ecosystem of the digital market space [11, 12]. The digital economy enhances the role and importance of the company strategy, which is directly related to soft skills of managers (such as mission statement development and teamwork) and to the tacit knowledge that cannot be easily shared with others [23, 24]. Here, management also has to choose between reactive and proactive types of market orientation, as well as "market-driven" and "market-driving" types of strategic behavior of the company in the process of BD (Fig. 2).

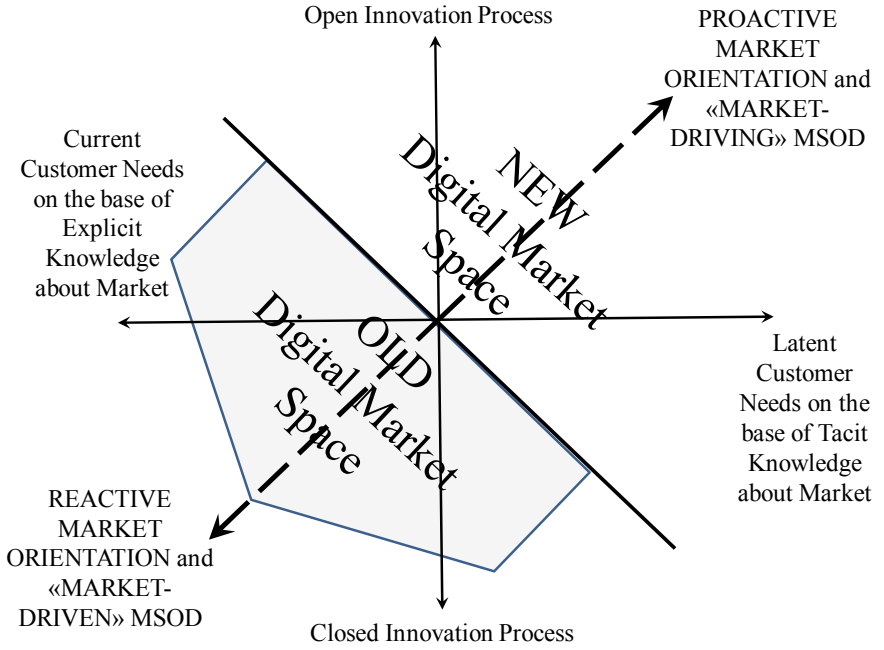

Fig. 2 Dualistic nature of market orientation and types of digital strategic market behavior [11]

BD should be considered rather a final point than a process. This is a series of successive arrangements of various scales taken by the management using digital technologies [11, 21, 25]. In our opinion, the range of possible MSCD in the Internet space can be represented as two opposite groups by the extent which the digitalization penetrates all business areas from the perspective of VCS (Fig. 3):

(1) digitization of individual business processes—integrating digital technologies in current value chains and, if necessary, replacing offline links with online within chain VCS;
(2) digital transformation—making strategic changes to all business processes and, ultimately, the transition of the entire company to fundamentally new ones, i.e. network VCS.

As can be seen from Figs. 2 and 3, the "pull-by-market" digital MSCD is based on the "digitization" of current market needs, i.e. identified by the company before the value creation. The "market-driven" digital MSCD is based on the BD of existing, or offline, markets. The "technology-driven" digital MSCD is delivered through the "digitization" offline platform and assumes that the needs for BD are met by the IT department, and the higher their novelty, the more likely it is for the company to fall into the "chasm" between myths and realities of the online market. In the information-knowledge paradigm, the "chasm" is impossible due to all actors concerning the invention of consumer value in building platform business models inside the chain

Type of Value-Creating System (VCS)	Scope of Digitalization: Business Processes Digitization	Scope of Digitalization: Digital Transformation
Chain	"Pull-by-Market" MSDO of Current Market Offers Digitization	"Market-Driven" MSDO of Digital Business Models
Network	"Push-by-Technology" MSDO of Platform Digitization	"Market-Driving" MSDO of Digital Ecosystems

Fig. 3 Typology of MSCD within the transition to a digital economy

VSC, with using the "market-driven" MSCD, and in creating ecosystems of markets, as a networked VSC through the "market-driving" MSCD. Moreover, in the co-creation consumer value within and between ecosystems makes it possible to combine "market-driven" and "market-driving" MSCD in the case of digital transformation of business. A company gains strategic flexibility when it not only anticipates market changes, but it also able to switch between different types of digital MSCD depending on the needs of the end-user [11, 12, 21].

4 Conclusions

The study allowed us to draw the following conclusions. The digital economy enhances the role and importance of the company's strategy, which is directly related to the soft skills of managers (such as mission statement and teamwork) and to the tacit knowledge which cannot be easily shared with others. The information revolution makes it possible to balance attitudes established in the industrial era and overcome cognitive barriers in MSCD, but raises requirements for an understanding of systemic and cultural challenges on the path towards BD. MSCD, given the scale of BD and differences in VSC, is becoming the object of modelling the behavior of market actors in the consumer ecosystem and a strategic marketing tool for configuring and recombining value flows in the "constellations" at the macro-, meso- and micro-levels of the digital economy.

Features of Relations between Government Authorities, Business, and Civil Society in the Digital Economy

Leila A. Maisigova, Shakizada U. Niyazbekova, Bibigul K. Isayeva, and Tamara Yu. Dzholdosheva

Abstract The rapid pace of development of information and communication technologies, the Internet, etc. is one of the key factors of globalization and determines the vector of progress to a new economy and civil society. The development that is being formed is called the digital (information) economy. Digitalization (Informatization) begins there and then, when its data changes people's behavior, their choice, and affects the comfort of human life. This equalization of social opportunities for access to the modern world, the displacement of people from solving simple problems. If there is enough data, the decision can be made automatically, without human intervention. As a result, happens a decrease in subjectivity during decision management, and an increase in the speed of their enactment. The goal of this research is to identify the features of new socio-economic relations that arise in the process of management and to elaborate separate provisions for the development of electronic services in the digital economy. Results:

1. It is found out that modern information processes actualize the problems and methods of organizing the economy and the community to ensure sustainable development.
2. The analysis showed that the development of electronic services is also accompanied by the creation of new transaction costs in information protection, identity protection, user identification, distortion and loss of information, etc.

The analysis of the relationship between government authorities, business structures and civil society in the digital economy should begin with methodological approaches to research transaction outlays that arise in the process of these relationships.

Keywords Digital economy · Information asymmetry · Electronic public services · Transaction costs

1 Introduction

Information in the XXI century is a fundamental information strategic resource and the one who owns it gets the most important lever of influence for managing socio-economic and political development.

A number—is a comfort and convenience that allows getting access to the goodness in the shortest time. It's an equalization of social opportunities for access to the modern world; the displacement of people from the field of solving simple tasks.

If there is enough data, the decision can be made automatically, without human intervention. As a result, happens a decrease in subjectivity during decision management, and an increase in the speed of their enactment [1–22].

However, it is impossible not to take into account, as a disadvantage, the possibilities of total control provided by the number to its administrators.

2 Background and Methodology

The history of the development of the new state was accompanied by the complication of forms and methods of management and control, which was accompanied by an increase in parameters and the need to diversify the structure of state and political entities. In today's reality, the use of modern information and communication technologies will allow us to reasonably correct this vector of development to the opposite one.

The growth of transformational processes actualizes the problems of searching for breakthrough ideas and methods of organizing the economy and the community for development.

Informatization is the translation of current human activity into electronic form. Digitalization allows you to get access to the goodness in the shortest time. For example, a student receives individualized educational content; remote medical care-consulting by leading doctors.

To get the desired result, we need to create an interface that the consumer can access certain services remotely and easily, and also simultaneously evolve the digital culture.

Automation of routine is an advantage because it displaces a person from solving simple tasks. If there is enough data, the decision can be made automatically, without

human intervention. As a result, this leads to a decrease in subjectivity in decision-making, and an increase in the speed of decision-making. However, we can not ignore the fact that control is concentrated in the center of administrative management of processes.

The methodology used in the article is based on the basic principles of a systematic approach creating a rational organization of corporate financial performance management in the digital economy. In the article, provisions of the classical theory, provisions of the main concepts of the theory of standardization, and the digital economy are used.

3 Discussion and Results

The rapid pace of development of information and communication technologies, the Internet, etc. is one of the key factors of globalization and determines the vector of promotion of a new type of economy and civil society. The type of development that is being formed is called the digital (information) economy.

Among the most typical features of the digital economy, we can stress the transfer of most of the socio-economic processes to the electronic space, popularization of remote employment methods, squeezing out hard work by robots, use of electronic money, and electronic democracy.

Conducting a transaction analysis of the relationship between government authorities, business structures, and civil society is reasonable to start with methodological approaches of transaction outlays.

The analysis of special literature on this issue allows us to understand transaction outlay as the costs of the interaction of economic agents and neutralization of distributive conflict between subjects [23].

In general, transaction outlay is the outlay application of the market mechanism of interaction in the process implementation of activities. Transaction outlays in its true sense are the sum of market costs, coordination of activities and mutual agreement of interests within enterprises about the formation of an information base, strategic plan, controlling, etc.

Among the main factors in the formation of transaction outlays we can point out the limited rationality of economic agents, the unpredictability of the future period, information asymmetry and availability opportunities for the opportunistic behavior of contractors.

The limited rationality of economic agents is understood as their certain limitations in the ability to formulate a goal and plan the possible consequences of their management decisions.

Information asymmetry means that participants' interactions have different access to information. For example, the relationship between a seller and a buyer.

Opportunistic behavior is typical of economic systems agents prone to constant profit-taking, they are even using (dishonest) deceitful plans. To do this, they

often violate the rules and do not execute the obligations, conceal or misrepresent information, etc.

It is also appropriate to note here the problem of multiple marginalizations. It emerges itself in the desire of producers to maximize profits on both intermediate and final products–so-called double marginalization. It is observed in markets of imperfect competition in the form of unjustified inflated prices for goods and services, which allows you to maximize the profit of all participants in the production and marketing processes.

The effect of repeated marginalization in the provision of public services is reflected not in the monetary form of producers' profits, but an unjustified increase in consumer spending related to the need for interaction between recipients of public services.

In these conditions, production faces an urgent problem the necessity of creating transaction outlays. This makes the government influence purposefully on a set of objective factors that generate excessive transaction costs, including the unpredictability of the future, information asymmetry, etc.

For this, first, it is necessary to improve legislation and law enforcement practices regarding specification and protection of the rights of economic agents; develop industrial policies, including reducing macroeconomic instability; improve the organizational structure of management; encourage various forms in the self-organization of civil society institutions.

All of this will help to alleviate the problems of information asymmetry, reduce most of the transaction outlays, etc.

The best example is the classification of transactional outlays, proposed by T. Eggerson. He offers to consider transaction outlays as the form of a set of outlays for searching information, conducting negotiations, concluding contracts, monitoring, controlling, protecting property rights [24]. Their generalization will allow us to talk about at least six main classification criteria of transaction outlays:

– education sphere;
– degree of the legality of education;
– time of signing the contract;
– reasons for education;
– type of transaction;
– the content of actions that generate outlays.

Experts understand that in a short period of time, the system of e-government services managed to significantly reduce most of the traditional (increased) transaction outlays [25].

However, it should also be noted that certain types of traditional transaction outlay related to quality measurement services monitoring the implementation of services, and others increase.

Moreover, the development of electronic services is also accompanied by creating new transaction outlays in the protection of information, identity protection, user identification, misrepresentation and loss of information, etc.

It also should be noted that most parts of the history of the development of the new state were accompanied by the complication of forms and methods of management and control, which was noted by the increase in parameters and the need to diversify the structure of state and political entities. Today, the use of modern information and communication technologies (ICTs) will allow us to reasonably correct this vector of development to the opposite.

Increasing the use of ICT has not only neutralized many traditional transactions outlays but also generated new types of it, including outlays of protection of the information, the outlays of its interpretation, the outlays of distortions, etc.

Currently, there is forming a complex of new production facilities technologies that combine:

– information technology;
– industrial robotics;
– sensor technologies and many others [26].

4 Conclusions

Thus, the generalization of foreign experience interactions government, business, and civil society allowed us to highlight its key role in the formation of a sustainable economy with signs of investment attractiveness of companies for investors, highlight its features because of a significant effect of public administration and control in the digital economy.

We think it is necessary to take these features into account during the development of Russian standards of public administration business-processes in the new economic conditions.

The proposed changed approach will allow the government authorities, companies and civil society to improve the management system, increase investment attractiveness to strengthen the confidence of investors based on objective information.

There is no doubt that the development of the digital economy allows us to enhance interrelation of all political, social and economic factors; it will help to raise awareness and simultaneously form new opportunities and types of opportunism.

The Role of Gross Profit and Margin Contribution in Decision Making

Oksana S. Evmenchik, Shakizada U. Niyazbekova, Favziya S. Seidakhmetova, and Tatyana M. Mezentceva

Abstract The decisions necessary for urgent adjustment of the strategy during the budget period, as well as those associated with "negative" economic activity, are classified. Four critical points, five intervals of production volumes, dynamics of the financial result behavior by the methods of Absorption and Direct costing, and decision-making on prices, financial results and decisions of the type "to be or not to be" were investigated. Classified solutions decisions necessary for urgent adjustment of the strategy during the budget period, as well as related to «negative» economic activity. Researched four critical points, five intervals of production volumes, the dynamics of the behavior of the financial result by the methods of Absorption and Direct costing, and decision-making on prices, financial results and decisions of the type «to be or not to be».

Keywords Financial results · Profit · Losses, gross profit · Marginal contribution · Production and non-production costs · Variable and fixed costs

1 Introduction

Financial indicators are used to make decisions by managers and owners of capital on the current short-term and long-term investment activities of the organization. However, financial information obtained on the basis of financial accounting data has a number of shortcomings: factual information about past results, aggregation, averaging of data, not enough realism, distortion. Therefore, financial information is needed, obtained for decision-making by managers and owners of capital, with the following characteristics: analytical information based on a comparison of plan and fact, detailed data, maximum realism. This is a system of managerial accounting, internal financial control, which includes a number of techniques—budgeting and deviation detection, cost management methods, methods for determining the financial result of Absorption and Direct costing, a balanced scorecard for decision making.

2 Background and Methodology

In order to generate financial statements established by the legislative bodies of all countries in accounting, financial accounting, to calculate the financial result, the classification of costs is used for: product costs and period expenses.

The use of this classification requires the determination of the following indicators of external financial reporting or calculation at full cost (**Absorption costing, Conventional format**):

(1) partial or incomplete production cost of goods sold (cost of goods sold), calculated on the volume of products sold;
(2) non-production expenses of the period (operating expenses), consisting of administrative expenses and expenses for implementation;
(3) gross margin from sales—an interim financial result on sales, defined as the difference between net sales, i.e. revenue from sales without indirect taxes (net sales) and cost of goods sold (cost of goods sold).
(4) operating profit from sales—the final financial result of the sale, i.e. current activities, defined as the difference between gross margin from sales and non-operating expenses of the period (operating expenses).

For the organization to work effectively, managers and managers need to make many managerial decisions, observe the interests of customers and shareholders, balance between goals that may conflict with each other. The resolution of these conflicts requires compromise solutions that affect all processes of the organization.

Operational business activity poses many additional tactical tasks in the process of daily decision making by managers. Analyzing additional tasks of operational activities, we can distinguish three types of decisions that affect the organization's overall strategy and require immediate adjustment of the strategy during the budget period:

Types of decisions required for urgent strategy adjustment during the budget period:

(1) making decisions on changing market prices of products. This type of solution can be divided into two areas: rising prices and lowering prices. In countries with tangible inflation, as a rule, capital owners and managers are faced with a process of reasonable price increases and do not think about the compelled problems associated with lower prices.
(2) making decisions on the basis of financial results on the existence of the economic activity of a product, direction, project, branch, representative office. This type of decision can be divided into two areas: a positive financial result or negative. During periods of growth or the presence of a high positive financial result, capital owners and managers do not think about the compelled problems associated with a decrease in profits, moreover, with the presence of operating losses.

Periods of decline in economic activity, welfare of the population, i.e. economic recession, introducing special additional tasks for the management of operational activities, which previously, as a rule, were not faced by young managers and, accordingly, experience in decision-making was not gained.

These additional tasks related to the deterioration or "negative" economic activity, we will divide into three types of decision-making.

Types of decisions related to deterioration or "negative" economic activity:

(1) a decrease in market prices by competitors. The process of lowering market prices by competitors during the period of the so-called "price wars" becomes more relevant.
(2) the deliberate establishment of low market prices during the period of launching a new product, an innovative project;
(3) the urgent termination or not economic activity of the product, direction, project, branch, representative office. The presence of operational losses and the adoption of decisions only in terms of operating profit often leads to the adoption of incorrect decisions and the closure of new directions, the reduction of projects and small businesses.

Identified three types of decisions, affect the overall strategy of the organization, require immediate adjustment. The use of financial data based on the classification of product costs and period expenses does not allow these tasks and decisions.

To carry out these tasks in daily operational deteriorating activities, it is necessary to introduce into financial management the definition of variable product costs that vary with the volume of production.

The use of classification of variable and fixed costs for calculating the financial result in management accounting provides a wider coverage of information and allows for a better analysis of possible trade-offs, allocation of resources and costs, adoption of various kinds of management decisions [1].

The application of this classification requires the determination of the following indicators of internal financial statements or variable costing (**Direct costing, Contribution format**):

(1) the incomplete cost of goods sold at variable costs (variable costs of goods sold), calculated on the volume of products sold and variable costs of the period (variable period expenses). The sum of the incomplete cost of sales for variable costs and variable costs of the period is called the sum of the variable costs of production and non-production nature (variable costs);
(2) fixed costs (fixed costs), consisting of the sum of fixed production costs (fixed costs of goods sold), fixed administrative costs and implementation costs (fixed period expenses);
(3) the contribution margin or marginal income, profit margin (Contribution margin from sales)—an interim financial result on sales, defined as the difference between net sales, i.e. revenue from sales without indirect taxes (net sales) and the sum of variable costs of production and non-production nature (variable costs).
(4) operating profit from sales—the final financial result of the sale, i.e. current activity, defined as the difference between the margin profit (sales margin from sales) and fixed costs of a production and non-production nature (fixed costs).

The methodology for calculating gross and marginal profit is given in the classical literature on management accounting of such scientists as Apcherch [2], Horngren [3] and others [4–25].

3 Discussion and Results

The method of financial management accounting Direct costing is used:

(1) to justify changes in the market prices of products, to identify the minimum level of the market price and make decisions on prices;
(2) to calculate the real financial result of the product, identify the minimum level of costs for the production and sale of the product and make decisions on whether or not the economic activity of the product, direction, project, branch, representative office exists;
(3) for short-term financial forecasting of sales and profits, identifying critical volumes of products, conducting a cost-value analysis (financial value profit analyses) and financial justification of the feasibility of tactical, operational proposals by managers to make decisions by capital owners as part of a changing strategy.

The direct costing method is called breakeven analysis (CVP analyses). It was developed in 1930 by an American engineer, Walter Rautenstrach, as a planning method using a critical production schedule.

Any enterprise, developing business plans, evaluating actual sales volumes should compare them with critical volumes.

As a rule, in classical CVP analysis, from one critical point (break-even volume) to three (break-even volume, liquidity volume, predetermined profitability volume) and, accordingly, for decision-making, four classical intervals of production volume are considered.

However, taking into account decision-making not only on financial performance, but also on minimum market prices, and whether or not the business activity of a product or project is closed, four critical points and five decision intervals developed in this study should be distinguished, see Fig. 1.

Four critical points developed in this study should be distinguished instead of one or three proposed by classical views.

Types of critical points considered in decision making:

(1) the point of flight of the company corresponds to the volume at which the market price is equal to the minimum value of average variable costs (P = minAVC) or the revenue from sales of products is equal to the value of the minimum total variable costs (TR = minTVC);
(2) the liquidity point corresponds to the volume at which the market price is equal to the minimum value of average costs without depreciation (P = minAC-Am) or the revenue from sales of products is equal to the minimum total costs without depreciation (TR = minTC-Am);
(3) the break-even point corresponds to the volume at which the market price is equal to the minimum value of average costs (P = minAC) or the revenue from sales of products is equal to the minimum total costs (TR = minTC);
(4) the point of a given profit (profitability) corresponds to the volume at which the market price is greater than the minimum value of average costs (P > minAC) or the revenue from sales of products is greater than the value of minimum total costs (TR > minTC).

Thus, the critical points are the boundaries of five, and not four, classic intervals of production volumes and product sales, considered when making decisions, see Table 1.

Intervals of volumes of production and sales of the product considered in decision-making:

The first interval includes volumes from zero to the point of "company flight". Sales volumes do not cover own costs for the production and sale of the product, i.e. variable costs. All financial performance indicators are negative: both gross and marginal profit, and, accordingly, operating profit. The amount of losses consists of the sum of fixed costs and a partial amount of variable costs. With this financial situation, the project should immediately cease and leave the economic activity of the project. Since at zero volumes of the project, the operating loss will be less and amount to fixed costs.

At the very point of the "company flight", despite the negative values of gross and operating profit, the marginal profit is zero. This means that the project fully covered its own costs for the production and sale of the product, i.e. variable costs.

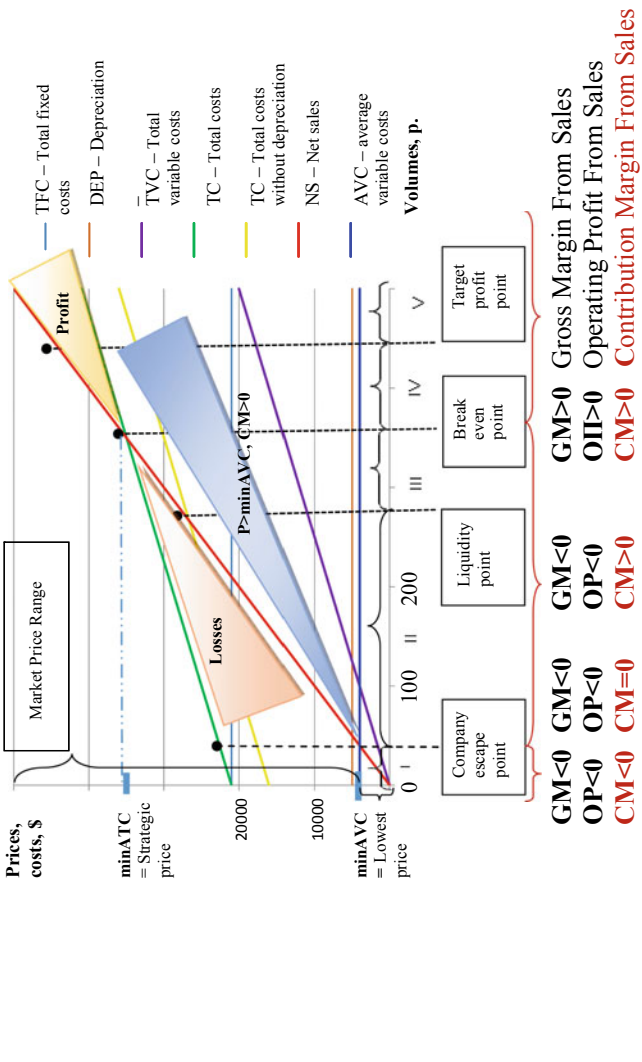

Fig. 1 Range of market prices, critical points and intervals, indicators of financial performance for decision making. *Note* Compiled by the authors

Table 1 The level of market prices and indicators of financial performance at critical points necessary for decision-making

	Point «zero volume»	Company escape point	Liquidity point	Break even point	Target profit point
Contribution margin from sales	CM < 0	CM = 0	CM > 0	CM > 0	CM > 0
Gross margin from sales	GM < 0	GM < 0	GM < 0	GM > 0	GM > 0
Operating profit from sales	OP < 0	OP < 0	OP < 0	OP = 0	OP > 0
Economic profit	EP < 0	EP < 0	EP < 0	EP < 0	EP > 0
Market price range	P < minAVC	P = minAVC	P > minAVC и P < minATC	P = minATC	P > minATC

Note Compiled by the authors

The amount of losses will be the sum of fixed costs, i.e. financially equivalent to either abandoning or continuing a project. However, the consumer is already familiar with this type of product on the market. It is necessary to further develop the sales of the project, attracting all the professional resources and management of the organization, so that sales will cover not only all the variable costs, but also constant and possibly earn the desired profit. Project management should not be left alone with problems; urgent professional management assistance is needed.

The first interval is also characterized by prices from zero to the point of "minimum level". The minimum level of the market price is equal to the minimum value of average variable costs (P = minAVC), and also reflects zero marginal profit, which, accordingly, is the lower limit in possible critical discounts for market prices.

The second interval includes volumes from the point of "company flight" to the point of liquidity. Sales volumes cover their own costs for the production and sale of the product, i.e. variable costs, and also partially cover fixed costs without depreciation. Marginal profit is positive, despite the negative value of gross and operating profit. The amount of losses consists of a part of fixed costs without depreciation. The project management cannot be left alone with problems; urgent professional managerial assistance is needed.

Continued work in the second interval will lead to bankruptcy, because the owner not only gradually loses the fixed capital spent, but, in addition, is forced to conduct a cash search to recover a partial loss of working capital. The company is in crisis.

The second interval is also characterized by prices from the point of "minimum level" to the strategic price.

The third interval includes volumes from the liquidity point to the breakeven point.

Sales volumes cover their own costs for the production and sale of the product, i.e. variable costs, and also partially cover fixed costs including depreciation charges. Marginal profit is positive, gross profit can also be positive, despite the negative value of operating profit. The amount of losses consists of a part of fixed costs. The project management cannot be left alone with problems; urgent professional managerial assistance is needed.

Continued work in the second interval leads to a complete loss of fixed capital, as the owner loses part of the depreciation deductions.

The third interval is also characterized by prices from the "minimum level" point to the strategic price.

The fourth interval includes volumes from the breakeven point to the point of a given or target profit. Sales volumes cover their own costs for the production and sale of the product, i.e. variable costs, as well as partially cover all fixed costs, including depreciation. Margin profit, gross profit are positive, operating profit is zero. The company has no losses. The project covered all its variable costs and earned the amount of fixed costs in the total contribution of the activity.

With volumes greater than the breakeven point, the owner makes a profit from current activities. However, long-term work in this interval is economically inefficient, since the payment for own and borrowed investments is partially compensated (in many cases it is more profitable to keep money in a bank than to invest for work in the third interval).

The fourth interval is also characterized by prices from the point of "minimum level" to the strategic price. The strategic price corresponds to the minimum value of all average costs (P = minATC), reflects the absence of operating losses, and most importantly, positive marginal profit and gross profit.

The fifth interval includes volumes greater than at the point of a given profit. With the volumes of this interval, sales cover all costs and bring positive operating, gross and marginal profit, and the owner is provided with economic profit (economic effect), obtained as the difference between operating profit and alternative income.

The more projected volumes of production are distant from the point of a given profit (profitability), the higher the financial stability and business activity of the enterprise and the more attractive the investment for investors. At the same time, it ensures the receipt of net profit, repayment of the loan, payment for the loan, covering current costs, the source of financing of which is this profit.

The fifth interval is also characterized by prices from a strategic price and higher. These prices are above the minimum value of all average costs (P > minATC), reflect the positive operating, gross and marginal profit, as well as the presence of economic profit.

Making decisions on the economic activity of the project "to be or not to be"

Analyzing the dynamics of the financial result by the two methods of Absorption costing (AC) and Direct costing (DC), it is possible to note the features of the behavior of profit. For the AC method, the nature of profit behavior is closer to changes in the production volume curve, and the profit calculated by the DC method more accurately conveys the behavior of the sales volume curve.

Table 2 Profit and loss statement of projects "A" and "B" in the format of absorption costing

Project "A"		Project "B"		Total	
Absorption costing	$	Absorption costing		Absorption costing	$
Net sales	00	Net sales	160	Net sales	260
Cost of goods sold	110	Cost of goods sold	90	Cost of goods sold	200
Gross margin from sales	(10)	Gross margin from sales	70	Gross margin from sales	60
Operating expenses	30	Operating expenses	50	Operating expenses	80
Operating profit from sales	(40)	Operating profit from sales	20	Operating profit from sales	(20)

It should also be noted that in the conditions of negative operating profit, decision-making on the economic activity of a project of the type "to be or not to be" is financially justified only by the Direct costing method.

Suppose a company produces two projects—A and B. The production costs are presented in Table 2. Project "A" is unprofitable. A decision needs to be made: whether to continue project "A" or whether it should be closed.

According to the AC method, project "B" was profitable at $ 20, while project "A" was unprofitable at $ 20. Total loss on projects 20 cu Operating Losses Lead to Strategic Decisions:

Decision 1. If a decision is made to close project "A", then a significant part of the fixed costs will not be reduced, but will be transferred to project "B", thereby reducing its profitability and even lead to losses in general (Table 3).

Project "A" is closed. Project "B" has a loss of 10 conventional unit, instead of a profit of 20 cu. Total sales decreased by 100 cu, and profit by 10 cu Total loss of 20 cu, but the company has one project in its assortment.

Solution 2. We will determine the financial performance of project "A" in the "Direct Costing" system.

Table 3 Profit and loss statement of projects "A" and "B" in absorption costing format, project "A" was closed

Project "A"		Project "B"		Total	
Absorption costing	y.e.	Absorption costing	y.e.	Absorption costing	y.e.
Net sales	–	Net sales	160	Net sales	160
Cost of goods sold	–	Cost of goods sold	90	Cost of goods sold	90
Gross margin from sales	–	Gross margin from sales	70	Gross margin from sales	70
Operating expenses	–	Operating expenses	80	Operating expenses	80
Operating profit from sales	–	Operating profit from sales	(10)	Operating profit from sales	(10)

Table 4 Profit and loss statement of project "A" in the format of absorption and direct costing

Project "A"				Project "B"	
Absorption costing	y.e.	Direct costing	y.e.	Absorption costing	y.e.
Net sales	*100*	*Net sales*	*100*	*Net sales*	*160*
Cost of goods sold	110	Variable cost of goods sold	40	Cost of goods sold	90
		Variable period expenses	20		
Gross margin from sales	*(10)*	*Contribution margin from sales*	*40*	*Gross margin from sales*	*70*
Operating expenses	30	Fixed cost of goods sold	70	Operating expenses	80
		Fixed period expenses	10		
Operating profit from sales	*(40)*	*Operating profit from sales*	*(40)*	*Operating profit from sales*	*(10)*

Project "A" by the AC method is unprofitable: gross loss of 10 cu, operating loss of 40 cu According to the DC method, the production and implementation of project "A" is profitable: a marginal profit of 40 cu This means that the sale of project "A" 100 cu fully covers all costs associated with the production and sale of goods, 60 cu (Table 4).

The remaining amount of marginal profit is 40 cu not enough to cover the increased amount of permanent production 70 cu and administrative costs 10 cu, only 80 cu Therefore, project "A" incurs an operating loss of $ 40.

Thus, if a project earns a marginal profit, then it is beneficial to the company, despite the negative values of gross profit and operating profit. Total total loss of $ 20, but the company has two projects in stock.

Decision 3. The necessary urgent operational decision that affects the change in the organization's strategy: either increase sales of Project "A" or reduce the amount of fixed costs of the entire enterprise or simultaneously perform both tasks.

4 Conclusions

Thus, the marginal profit indicator compared to gross profit has many practical advantages in the process of operational management of managers, decision-making and timely change of strategy by capital owners:

(1) allows you to quickly study and predict the relationship between volumes, costs and profits;
(2) helps to quickly solve a number of management tasks with the help of advanced CVP analysis;

(3) allows you to justify and choose an effective pricing policy;
(4) provides extended information on financial indicators for making strategic decisions in the difficult circumstances of operating losses.

Problematic Aspects of Management in Creating Social Real Estate Facilities Based on Information Modeling Technology

Natalia A. Moiseenko, Nikita A. Sityamin, and Kamol Komilov

Abstract Issues of social orientation and economic orientation have always been and remain among the priority areas of development. One of the main tools for solving social problems is housing construction and construction of social facilities. In addition, the need for housing is constantly growing due to positive changes in the structure of the population and its migration across the territory of the Russian Federation. Construction and modernization of social facilities refers to the most important task for the Russian Federation. Significant position at all stages of the property's life cycle is determined by the state, and therefore the main source of funding for the implementation of this task is the budget allocations of the Federal budget. One of the problematic aspects of the construction process that affects the effectiveness of the entire project is the management and interaction of participants. The main solution to this difficulty is to apply information modeling methodology. In this regard, it is necessary to form and implement an organizational and economic mechanism for managing the process of coordinated work of all participants in social projects. As part of the creation of such a mechanism, a classifier of management and information interaction can act, which will allow all industry participants to most effectively determine how to solve the tasks and increase the effectiveness of the entire project. The article defines the main criteria for evaluating the proposed classifier. Among others, it is necessary to take a breakdown of management functions into subfunctions depending on the purpose of the social facilities, which in turn will allow the use of several models of management technologies, taking into account the configuration and type of social facility, based on a synopsis of information about the project.

1 Introduction

Now the building branch is aimed at development and the perfection connected with replacement of standard methods of designing and building of investment-building projects, in other words, namely stage-by-stage replacement of means of information interaction of participants of the project on the most innovative, based on smart-technologies (On approval of the State Program of the Russian Federation No. 316, 2019; On approval of the State Program of Moscow "Housing" No. 237-pp 2018).

Rather high complexity of innovative methods is connected with absence of reliable and actual information necessary for setting and solving the tasks and increasing efficiency of the whole project [1]. The difficulties identified are aimed at reducing the performance indicators of the individual project, thus contributing to a decrease in the quality indicators of the whole industry. One of the fundamental elements that require improvement in the construction industry is the control system.

Due to the fact that at present one of the important building spheres in the form and functional purpose is the social sphere of real estate objects, it is most relevant to conduct research in the given building sphere and to consider problem aspects of management on the basis of information modeling technology [2, 3].

The Russian Federation has also developed and approved a state program "Digital Economy of the Russian Federation" aimed at developing modern technologies. In the construction industry, the priority is assigned to the information modeling technologies of buildings and structures (BIM modeling) (Passport of the National Program "Digital Economy of the Russian Federation" 2019).

2 Methodology

2.1 To begin with, it is necessary to determine the essence of the information model of the real estate object. According to the American standard "National Building Information Model Standard Project Committee", it is a digital concept of physical and functional characteristics of the object [4] Building Information Model forms a publicly available information model or database on the investment construction project. It creates a stable platform for choosing solutions at all stages of the real estate object life cycle.

2.2 Building Information Modeling (BIM) is an information process which consists of constantly interacting digital information about a concrete object or its element at all stages of the project life cycle.

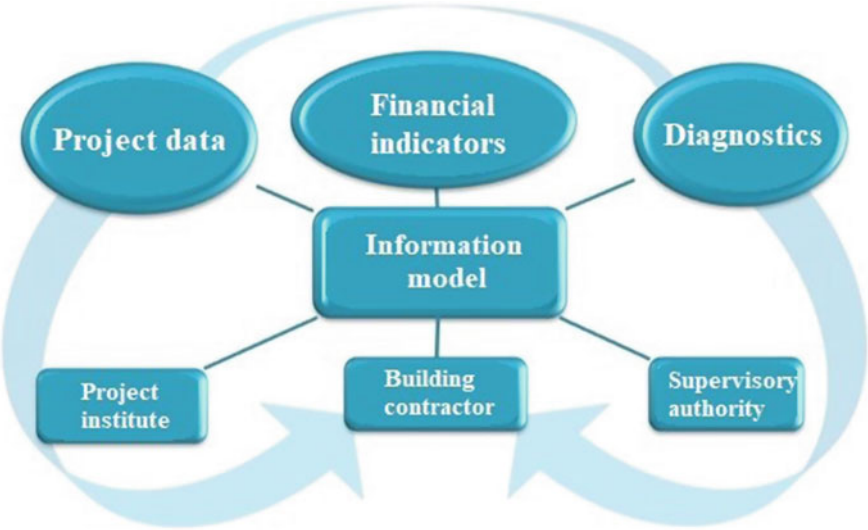

Fig. 1 Information model

The analysis of processes inside the subject organizations is required to form the criteria of interaction between the processes at all stages of the life cycle of the real estate object. The analysis is carried out by means of control and observation over the stages of data transmission and processing [5]. For all methods of interaction of subjects in the process of realization of the social facility of real estate, there should be formed interconnections, the results of which are the product or service provision. This interrelation of activity types is called a business process (Fig. 1).

BIM technologies are now becoming widespread in investment and construction projects. In turn, construction organizations are interested in the effective use of high-tech information technologies [6]. In this case the need for distribution of roles of participants of information model, their functions, tasks at creation of BIM model is formed. In other words, BIM technologies accumulate and analyze information processes at all stages of life cycle of real estate objects (Fig. 2).

2.3 Normative, technical and legal basis of information modeling in the construction of real estate objects.

Starting from 2016, the creation of real estate facilities that include social projects with the help of BIM technology is an integral part of the performance of works within the framework of government projects in such countries as: the Netherlands, Denmark, Norway and the United Kingdom [7]. On the territory of the Russian Federation, priority roles in the development of BIM modeling are assigned to the Ministry of Construction of Russia and the Department of Housing and Communal Services, that is, participation in the development of rules that govern information modeling, namely:

Fig. 2 BIM model

1. Code of Practice 328.1325800.2017 “Building information modeling. Components. Guidelines and requirements”;
2. Code of Practice 331.1325800.2017 “Building information modeling. Modeling guidelines and requirements of exchange data between information models and application package models”;
3. Code of Practice 333.1325800.2017 “Building information modeling. Modeling guidelines for various project life cycle stages”;
4. Code of Practice 404.1325800.2018 “Building information modeling”.

The development of the Russian Federation was approved by Presidential Decree No. 203 of 9 May 2017. In his Message to the Federal Assembly on February 20, 2019, the President of the Russian Federation also raised the issue of innovation in the construction industry, the development of the digital economy and “setting” the new technological reality (National Program Passport “Digital Economy of the Russian Federation” 2018). The result of such modeling is the Building Information Model. The given kind of information model serves as a decision-making basis throughout all life cycle of building object—from initial concepts of creation to working designing,

building, operation and demolition (Program for Renovation of the Housing Fund in Moscow 2017).

3 Results

3.1 Ranking of project management classes by main types of management activities (Table 1).

The main problematic aspects that arise from the application of BIM technology remain: typical decisions focused on decrease in cost of realization of the project are not developed; high demand for narrow experts; the high price of the necessary equipment and program complex; the low informative regulatory base of GOST-standards and Building Code standards (The Report on research "Level of BIM application in Russia" 2019).

3.2 The main advantages of BIM technology at life cycle stages.

Also it is necessary to notice that one of the main advantages of BIM technology is its efficiency, namely, when individual project characteristics are changed, automatic updating of parameters of interrelated materials is recorded. The fact of considerable improvement of the above mentioned technology is confirmed by the majority of participants of construction sphere who note impossibility in development of the investment and construction sector in the Russian Federation without BIM technology [8].

Table 1 Types of management activities

No.	Classes by type of management activity	Problematic aspects of realization of real estate objects of social importance by BIM technology
1	Administrative management	Absence of direct interaction between the developer and the explant at a design stage
2	Financial management	High cost of purchasing necessary hardware and software
3	Human resources management	Shortage of specialists whose professional activity is related to BIM technologies
4	Marketing and sales management	Due to the fact that the social object forms the main profit at the stage of operation, BIM technologies are used as needed in this process
5	Project management	There are no typical models and management practices for cost-effective reuse projects
6	Risk management	There are no plans to develop or model the process of selling the property, which depends on external environmental factors

Table 2 Information modeling at the stages of investment and construction project implementation

Step 1 designing	Step 2 construction	Step 3 operation	Step 4 renovation
1. The information model will allow to connect and simultaneously use all engineering solutions	1. All kinds of control functions are simplified	1. Quality of object management	1. Presence of all data about the object
2. The project's technical and economic performance is considered in one plane	2. Information system of databases for fast interaction of project participants	2. Operation control	2. Control of engineering systems and wear and tear indicators
3. Virtual reality models are used	3. Report function. 4. Dynamics of the construction process	3. Maintenance control	
4. Early collision detection of project documentation sections	5. Optimization of all types of resources	4. Availability of a database on the technical state of the project	

BIM technologies considerably improve management processes in the investment and construction project, on each of stages of its life cycle (Table 2).

3.3 Factors aimed at application of information modeling in construction of social objects.

Having considered the study "BIM Application Level in Russia 2019" (Message of the President to the Federal Assembly 2019), organized by the consulting company "Konkurator", the following results were published [9]. In the study of 2019, 541 companies took part and it was found that the level of application of BIM is 22% compared to 2017, which confirms the decrease in investment in the construction sector. In addition, with the help of online questionnaires work was done to analyze the reasons that had a significant impact on the implementation of BIM technology (Fig. 3).

3.4 The list of criteria for objects of social importance, at construction of which application of technology of information modeling should be obligatory.

Types of urban planning activity: design, construction, reconstruction, major repairs, operation, demolition.

Types of facilities: health care, general educational institutions, children's leisure facilities, sports complexes.

Sources of financing: with attraction of funds from budgets of the budgetary system of the Russian Federation, funds of legal entities established by the Russian

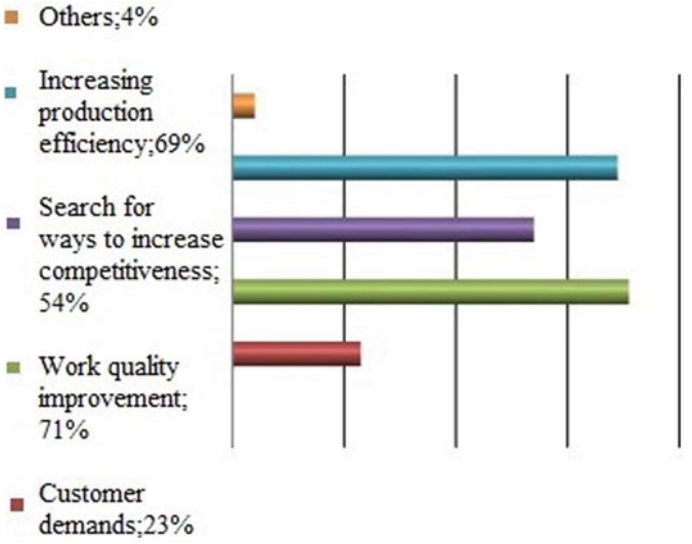

Fig. 3 Reasons for implementing BIM technologies in the company

Federation, constituent entities of the Russian Federation, municipal entities, legal entities.

4 Conclusion

By results of the analysis of application of BIM technologies at construction of the real estate social objects, the basic problems complicating application of the given technology and raising negative influence on efficiency of realization of all investment and construction project have been revealed. The following problematic areas should be highlighted:

1. Identification of tasks and functions of project participants;
2. Modernization of classification of main types of management activities in information modeling;
3. Development of an information matrix allowing project subjects to interact effectively with each other;
4. Development and approval of a unified program complex of information modeling for creating social objects;
5. Approval of the list of social real estate facilities, implementation of which is mandatory based on information modeling technologies.
6. Within the framework of formation of the organizational and economic mechanism of management of implementation of social projects, it is necessary to be

guided by the criteria of evaluation of the management classifier adapted to the specifics of real estate objects of the social sphere of economy.

It should also be noted that in accordance with the Decree of the Government of the Russian Federation No. 1030 of August 28, 2017 "On the management system of the program "Digital Economy of the Russian Federation" a task is set to develop the sphere of construction investment, which will make it possible to develop the information modeling technologies.

Institutional Framework for the Digital Future of Economic and Social Systems

Features of Agglomeration Effect of Regional Spatial System

Yuriy A. Salikov, Natalia I. Kuzmenko, Irina S. Zinovyeva, and Elena V. Korolyuk

Abstract Currently, there is a shift in the focus of socio-economic development from the macro level to the sectoral and regional levels. The need to study the trends and conditions of regional development, including the study of the features of the agglomeration effect, is of particular importance. Systematization of scientific ideas about the methodological aspects of the functioning and development of territorial entities is necessary, first of all, to justify decisions on the spatial distribution of productive forces in the context of the state, industry, region. The analysis of approaches to the definition of the content and essence of the concepts "territory", "space" and "region" showed that these categories are closely interrelated with each other, but do not reflect all the modern requirements and features of regional development. Therefore, the authors justify the need to use the concept of "regional spatial system", which allows for a deeper study of the synergistic features of the agglomeration effect within a specific territory. The study of the agglomeration effect in the Federal districts of the Russian Federation revealed a steady trend of growth in the urban population due to a reduction in the rural population. At the same time, there is a positive dynamics of the increase in large cities against the background of a decrease in medium and small cities. This circumstance can be considered as an actual manifestation of the agglomeration effect, which has both positive (from the point of view of the growth of productive forces) and negative sides (from the point of view of economic security). It is concluded that in order to solve the strategic tasks

of effective and safe development of modern regional spatial systems, it is necessary not only quantitative growth (through further agglomeration), but also qualitative integration of all organizational, technical and socio-economic components of the system.

Keywords Regional spatial system · Territory · Agglomeration effect · Synergy · Economic security threats

1 Introduction

From the theoretical point of view, the spatial development of the state can be uniform, but in practice it is almost impossible. Therefore, the goal of public administration is always to ensure the relative alignment of the level and quality of life of the population in the context of individual territories. Competent policy on management of available opportunities and potential of territories, efforts on overcoming of contradictions and reception of benefits from available effects of spatial development define qualitative characteristics of the spatial organization.

Currently, the use of a systematic approach to the study of changing economic conditions are becoming increasingly relevant. It allows us to identify the agglomeration effect of a regional spatial system, which is one of the most important attributes of systemic development. The attempts made to study the agglomeration effect prove that the concentration of production and other facilities in cities and agglomerations has a positive impact on the functioning and development of the regional space, it is an effective tool to increase competitive positions. At the same time, the agglomeration effect acts as a factor influencing the change of socio-economic characteristics of the system.

At the same time, this effect can generate disadvantages, such as social degradation, unemployment, lack of innovation, stagnation, which can become a source of real threats to the economic security of the regional spatial system.

Thus, the study of agglomeration effects of regional spatial systems and assessment of their impact on the development of enterprises, regions, States require further scientific justification.

2 Methodology

The scientific hypothesis of the study is the assumption that for the effective and safe development of modern regional spatial systems requires a new methodological tools that reflect the characteristics of the agglomeration effect of a particular territory.

On the one hand, the agglomeration effect, which consists in obtaining economic benefits from the territorial concentration of production and other economic objects in cities and agglomerations, can have a positive impact on the dynamics of the regional

spatial system (in terms of the growth of productive forces and the development of industrial relations).

On the other hand, it is a factor of social and economic instability, causing social degradation, increasing unemployment, reducing the innovative activity of economic entities, that is, it threatens its economic security. The solution to this problem can be to ensure quantitative growth by further agglomeration and qualitative integration of all organizational, technical and socio-economic components of the system.

To confirm the proposed scientific hypothesis the research attention was focused on solving the following issues to:

- justify the expediency of using the concept of "regional spatial system" in relation to solving problems of agglomeration effects management within a specific territory;
- study the specifics of agglomeration effects in the development of a regional spatial system;
- identify threats to economic security from the agglomeration effect of the regional spatial system;
- form a theoretical and methodological basis for the study of new properties and features of the regional spatial system development for the improvement of management processes.

To solve the tasks of the study, a comprehensive scientific toolkit was used, which, in particular, included the dialectical method, the method of scientific abstraction. In obtaining scientific results, the following applied methods were used: analytical, statistical, generalization and synthesis, comparison, system.

The theoretical and methodological basis of the study were the works of scientists on the study of the problems of the effect of territories (agglomerations) affecting the development of enterprises, territories, States and their economic security [1–4].

In the study of economic safety of region is considered as the totality of conditions and factors characterizing the stability of economy, stability and progressive development of the economy of the territory, degree of independence and integration with the national economy and the ability of the regional public authorities to create mechanisms of implementation and protection of interests of economic entities, to support socio-economic stability of the territorial community [5].

Methods and tools of forecasting and ensuring economic security are investigated in the works of Ovchinnikova and Horev [6], Karpunina et al. [7].

The study of agglomeration effects in the regional system requires clarification of the terminology used.

Thus, the term "space" refers to any logically conceivable structure or form that can serve as a medium for the implementation of certain structures or operations. However, often the term "space" is identified with the concept of "territory", while these categories have a number of fundamental differences. We prove this by comparative analysis.

Lyosh associated the category "space" with the placement of industry and the system of production and inter-territorial relations, and transport costs were determined as a factor of the functioning of space [8].

Probst [9], Granberg [10], Aganbegyan [11] justified the formation of "space" as a process of specialization of economic areas on the basis of territorial development planning.

At the same time generalization of opinions of experts in the field of natural Sciences allows to treat the concept "territory" as a part of space of the Earth and location of natural riches and resources, habitat of the person and a material basis of its existence. In addition, the "territory" is characterized by its socio-economic integrity, the presence of industrial and social infrastructure, which is necessary to ensure the living conditions of the population [12].

In the study of agglomeration effects in the regional economy, in our opinion, it is more expedient to operate with the concept of "space", since it allows more objectively reflect the concentration of production forces, industrial facilities, economic relationships, as well as to assess the effectiveness of production and economic activity within a certain territory from the standpoint of its economic security (Fig. 1).

We use the methodology of the system approach to study regional agglomerations and highlight the new definition of "regional spatial system". According to the researcher of the theory of systems Bertalanfi the system should be understood as a complex of elements that are in interaction, that is, the usual elements are not individual facts, but connections between facts [13].

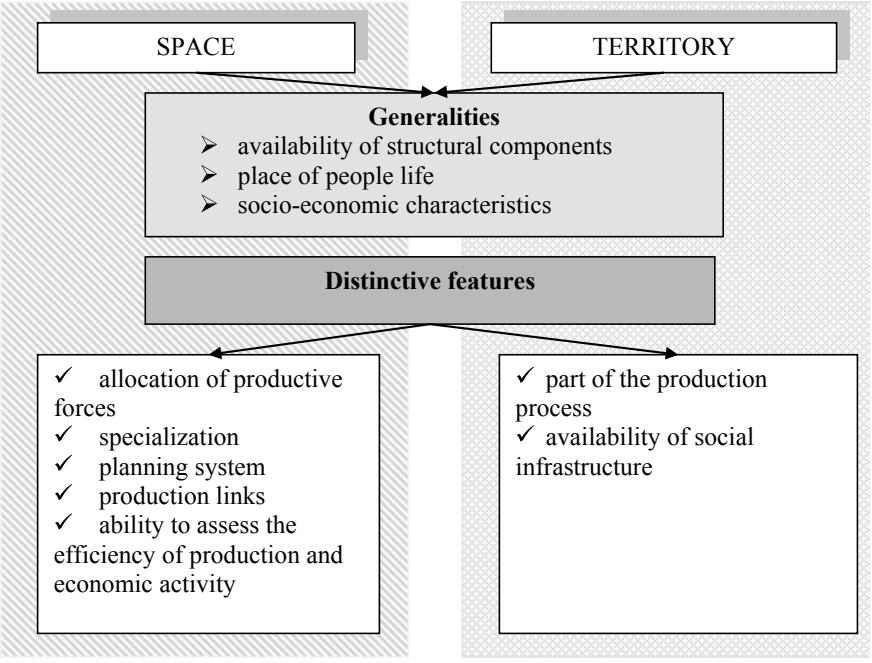

Fig. 1 Generalities and distinctive features in the content of concepts "space" and "territory" (created by the authors)

Thus, in accordance with the system approach, the regional spatial system can be considered as the location of a set of interrelated elements in their best combination, which assumes the presence of factors leading to socio-economic transformations aimed at ensuring the purposeful and safe development of the region. The peculiarity of this author's definition is, first of all, that the system approach is used in two planes: as a structural and administrative set and as a complete resource set (land, climate, and minerals; energy resources; finance; human resources and human capital; information resources). Thus, a regional spatial system is a unique combination of different resources, taking into account the characteristics of a particular territory (space, region).

3 Results

The nature of the development of a particular region is determined by the effective interaction of the components of the regional spatial system. Differentiation in the development of regional spatial systems may be due to the action of agglomeration effects and factors.

The agglomeration effect is a complex factor of placement and is expressed in the fact that point or compactly placed objects, if they are compatible, are always more effective than those placed in isolation, scattered [14].

Various approaches to the role of agglomeration effect of the regional spatial system are presented in the modern discussion field.

The concept of "agglomeration" is revealed in the works of numerous authors [15], Vlasova and Antipin [16], Grunina [17], Sapozhnikov [18].

Thus, scientists point out that the consequence of the process of agglomeration, manifested in the territorial concentration of industries and other economic objects, is the emergence of the agglomeration effect. Its essence is to sum up the territorial, industrial, economic and demographic potential of several territorial entities and achieve the most effective result through a comprehensive redistribution of resources and minimizing costs. The influence of the agglomeration effect is based on the components of the agglomeration structure (Fig. 2).

Thus, the agglomeration effect of the regional spatial system as a whole extends its effect to the conditions, processes and relations that generally influence territorial development.

Let us trace the effect of the agglomeration effect on the Russian regions example (Fig. 3).

Thus, the growth trend of large cities against the background of the decline of medium and small cities, the increase in the share of urban population is observed in many regions of Russia in the period from 2004 to 2018. North-Western Federal district (84.3%), Central (81.2%) and Eastern (75.1%) Federal districts are characterized by a high increase in the share in recent years (FSGSRF 2019).

This situation can be explained by the concentration of the working population to ensure the production sector.

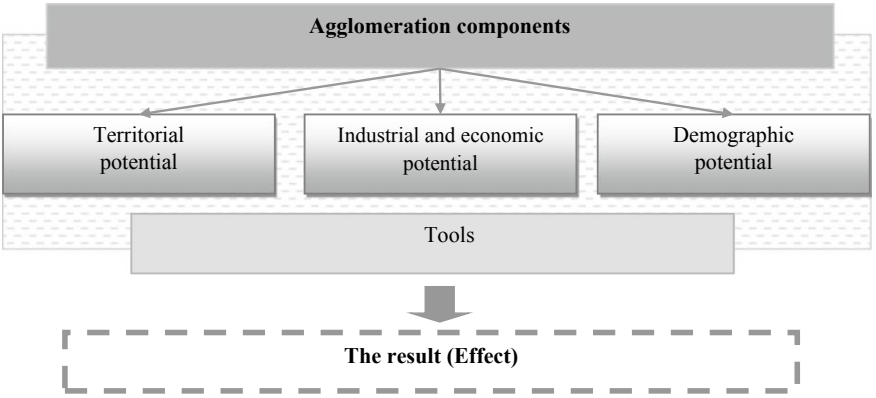

Fig. 2 Elements of the agglomeration structure of the regional spatial system (created by the authors)

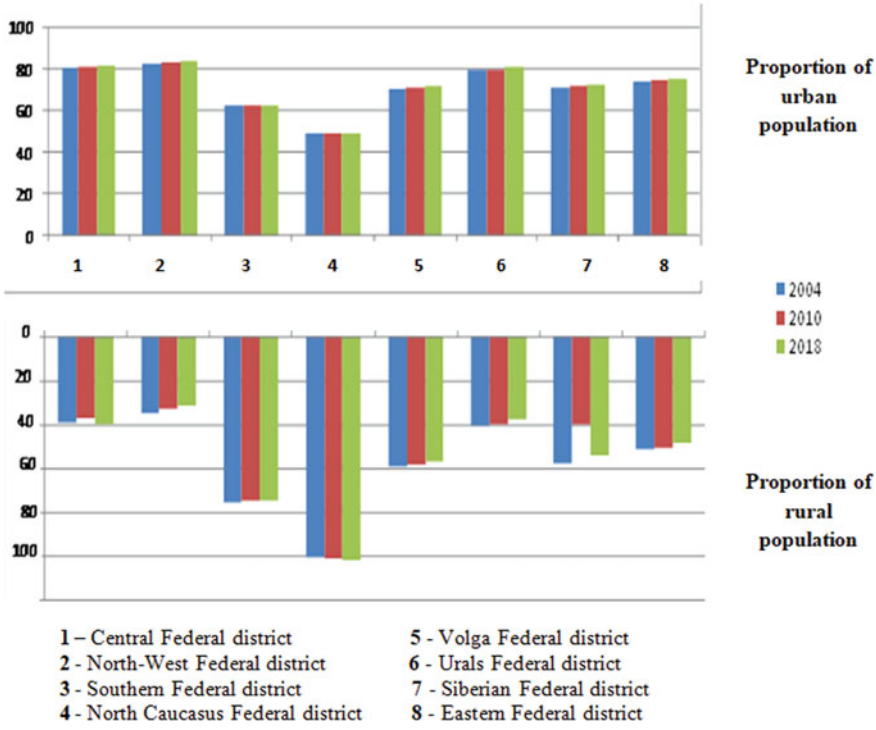

Fig. 3 The share of urban and rural population in the total population of the Federal districts of the Russian Federation, 2004–2018 (%), compiled authors according to the Federal State Statistics Service of the Russian Federation (FSGSRF 2019)

There is a positive dynamics of urban population growth in almost all Federal districts. Over the past 12 years, the share of urban population has increased in the Central Federal district (2%), the North–Western Federal district (2%), the Volga Federal district (1.8%), the Ural Federal district (2%), the Siberian Federal district (2.5%), and the far Eastern Federal district (1.7%). The exceptions are the Southern Federal district and the North Caucasus Federal district, where the share has not changed. The traditional agricultural specialization of the North Caucasus Federal district determines the low rates of urbanization of the population. The mobility of the population of this district remains low despite the development of transport and social infrastructure. The specificity of these provisions of the Southern Federal district consists in the natural loss of population and affects the negative dynamics of the share of urban and rural population.

The share of the rural population in the districts of the Russian Federation is a mirror image of the urban population. The dynamics of 2004–2018 shows negative values in the Central Federal district (2%), the North–Western Federal district (9.7%), the Volga Federal district (4.5%), the Ural Federal district (8.5%), the Siberian Federal district (6.6%), and the Eastern Federal district (5.3%). The Southern Federal district and the North Caucasus Federal district do not lose their share of the rural population. From 2004 to 2018 the share in the Southern Federal district decreased by 0.02%, in the North Caucasus Federal district-by 0.1%. As noted earlier, this fact is due to the natural loss of population and small indicators of migration growth.

The above conditions confirm the growth of urbanization in the districts of the Russian Federation. It is necessary to think about further trends in the manifestation of such growth in order to ensure the effective development of regional spatial systems.

This trend requires an in-depth study of the manifestations of the agglomeration effect in order to identify and assess its consequences for the socio-economic development of regions.

A number of authors substantiate predominantly positive manifestations of the agglomeration effect. For example, Kosinskij et al. [19] identify positive manifestations of the agglomeration effect of the regional spatial system in the form of reducing transport costs; more intensive use and development of infrastructure; expanding the range of goods and services; increasing the number of jobs; optimization of management costs (reduction of labor costs, payment for communication services, transport and utilities due to the reduction of administrations of territorial administrations); improvement of housing and communal services (unified policy for the collection and removal of waste throughout the agglomeration; installation and maintenance of street lighting); centralization of the system of formation, accounting and sale of land.

Animitsa [20] also substantiates some advantages of agglomeration effects: the joint use of scarce local factors of production by enterprises of different industries located in close proximity to each other, which are able to bring income to both an individual firm and the city as a whole; the emergence of new rental models (communication, transport and logistics, information, trade, financial); the formation of a single local (urban) labor market, ensuring the rapid movement of workers, especially with specific industry competencies and qualification characteristics from

one enterprise to another, contributing to the dissemination of new knowledge and information through personal contacts with employees of enterprises.

Rastvorceva [21] considers positive manifestations of agglomeration effect as territorial concentration of producers of consumer goods; territorial concentration of workers (consumers), territorial concentration of innovative activity. A greater number of firms in the city (region) offer new types of goods to consumers due to the effect of the home market (the gain from placing production next to the capacious market).

Thus, in the studies of different authors there are similar positive symptoms of the agglomeration effect, which together ensures the growth of socio-economic development of the territory.

However, the agglomeration effect, along with positive qualities for the territorial space, has negative values, leading to the degradation of entire regions (Fig. 4).

On the basis of the above, a number of generalized criteria and consequences of the agglomeration effect on the regional spatial system can be identified (Fig. 5).

It is possible to differentiate the Federal districts of the Russian Federation taking into account the selected generalized indicators of the regional spatial system. This will allow to:

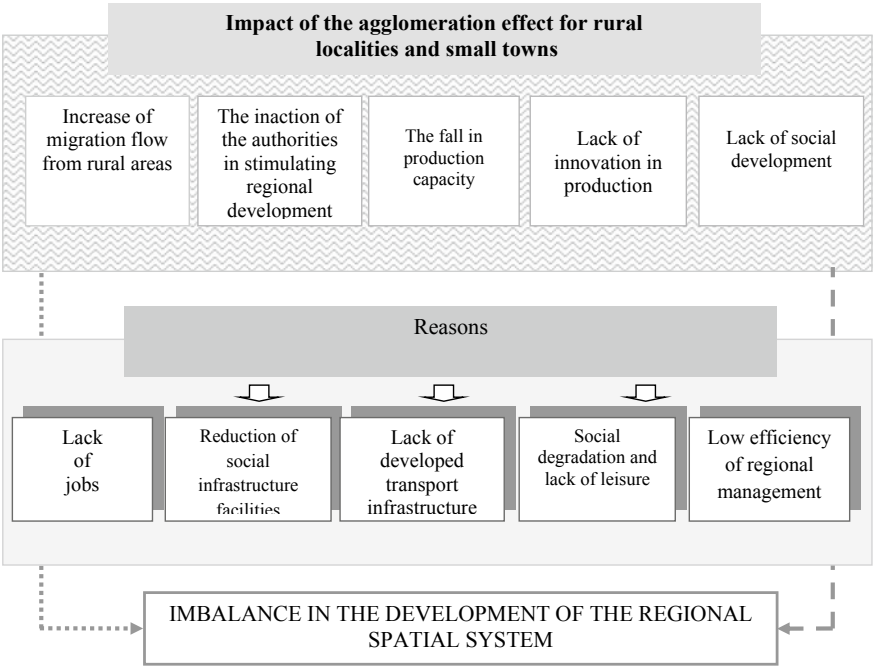

Fig. 4 Possible negative consequences of the agglomeration effect for the regional spatial system (created by the authors)

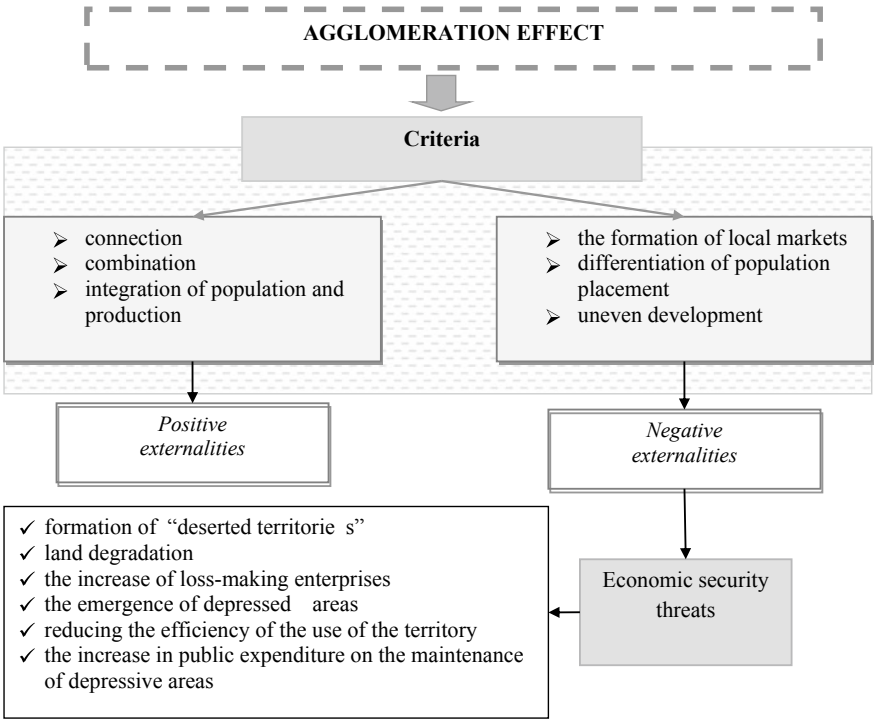

Fig. 5 Criteria and consequences of the agglomeration effect on the regional spatial system (created by the authors)

- show the influence of the agglomeration effect in the districts of the Russian Federation;
- clarify the degree of consequences of the agglomeration effect;
- identify the causes of the negative consequences of the agglomeration effect;
- identify ways to reduce the influence of agglomeration effect;
- strategize the regions taking into account the causes of agglomeration effect for rural areas.

The degree of influence of the agglomeration effect and, as a consequence, the formation of threats to the economic security of the regional spatial system is manifested in different ways.

Let us determine the validity of the indicators that justify the consequences of the agglomeration effect for the regional spatial system for the districts of Russia (Fig. 6). Let's take a sample of five indicators: migration flow, volume of output, volume of production of innovative products, works and services; unemployment rate.

The North Caucasus, Southern and Eastern Federal districts have the worst indicators [22, 23]. They are at risk of manifestation of threats to economic security. In

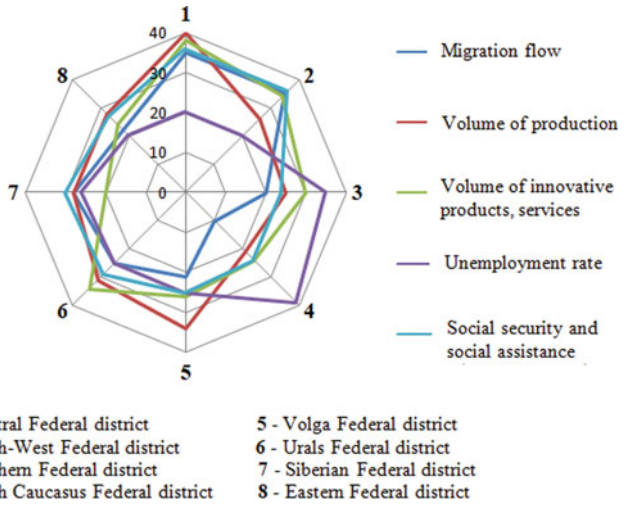

Fig. 6 Degree of influence of indicators of agglomeration effect on the districts of the Russian Federation for 2018 (compiled authors according to the Federal State Statistics Service of the Russian Federation (FSGSRF 2019))

connection with the identified circumstances, a possible solution is a combination of agglomeration effect with a synergistic effect of regional spatial systems.

In this regard, the synergistic nature of the agglomeration effect should be considered as the most important property of the functioning of the regional spatial system. This becomes especially important in the process of managing a regional spatial system, since the manifestation of the synergistic nature of agglomeration effects can also have different vectors of influence: on the one hand, you can observe a positive creative influence, on the other hand—increasing negative, destructive.

Thus, the study of agglomeration effects and their impact on the regional spatial system shows that the main task of regional management is to find ways and opportunities to obtain a positive effect from the manifestation of the agglomeration effect, as well as solving the problems of economic security that they generate [2, 7, 24–26].

Such threats include: escalation "deserted" areas; land degradation; unification of the goods and services that leads to a decrease in the degree of satisfaction of needs of the population, the quality of life of the population, worsening environmental problems; the increase in the number of unprofitable enterprises; the formation of depressed areas; reducing the effectiveness of the use of the territory; increase in public spending on the maintenance of depressive areas (Table 1).

All of these threats, according to our expert estimates, have a negative impact on the current state of the regional spatial system, while the degree of such influence varies insignificantly and for most of the identified threats is in the range from the average to the highest level.

Table 1 Economic security threats arising from the agglomeration effect of a regional spatial system

The name of the threats	Content	The possible level of impact (high, above average—average—below average—low)
Escalation "deserted" areas	Production, social infrastructure, and the production sector are absent in the territory, the territory has a low population density, the population decreases in an arithmetic progression (birth rate significantly prevails over mortality), and there are no migration processes	Above average
Land degradation	Increasing the land area of the region, where there is an effect of "abandoned" land in the process of forming "deserted" "territories", there are no opportunities for its effective use	Average
Increasing the number of unprofitable enterprises	Operation of non-competitive enterprises	Below average
Reducing the efficiency of the territory using	Negative trend of economic, demographic, social, and environmental indicators of development	High
The appearance of depressive areas	Integration of territories due to land degradation, the emergence of "deserted territories", reducing the effectiveness of the territory using, increasing budget expenditures as a help to depressed territories	High

4 Conclusions/Recommendations

The obtained results show that further scientific research in this area should be associated with the identification of features of the process of development of regional spatial systems, the formation of appropriate mechanisms of development management, as well as with the active use of mathematical tools to describe its specific features. The revealed features of manifestation of agglomeration effect of regional spatial systems are the basis for further researches of specificity of their functioning, formation of directions of fight against the threats generated by agglomeration effect, and also development of recommendations on implementation of effective regional policy.

In addition, further research on the development of regional spatial systems, in our opinion, should be balanced: these studies should equally focus on the conceptual aspects that form the theoretical and methodological basis, and on the identification of specific effects and their consequences for the successful functioning and development of regional spatial systems.

Quantitative assessment of the agglomeration effect is important in determining the degree of occurrence of negative effects for the functioning of the modern regional spatial system. In turn, the considered consequences of the agglomeration effect for the regional spatial system lead to changes in the organizational and technical (placement of production, complex development of industries, increase in production volumes, production infrastructure) and socio-economic (standard of living, social infrastructure, quality of life) components of the system, which, as a consequence, causes threats to economic security and necessitates the development of a system of strategic and tactical measures to prevent and prevent them.

The degree of influence of the agglomeration effect for the Federal districts of the Russian Federation confirms the authors' conclusions about the need for a qualitative integration assessment of changes in the components of the regional spatial system in order to identify threats to economic security and determine recommended measures to reduce them in the regions of Russia. The dialectical nature of the agglomeration effect allows us to conclude that in order to solve the strategic tasks of effective and safe development of modern regional spatial systems, not only quantitative growth (through further agglomeration) is necessary, but also qualitative integration of all organizational, technical and socio-economic components of the system.

Model of the Estimation of the Limit Efficiency of Integrating Taking into Account the Globalization Process

Ella Yu. Okolelova, Salimjon A. Nasriddinov, Alexey V. Shulgin, Larisa V. Shulgina, and Viktoriya V. Kompaniets

Abstract The authors consider the limits of the efficiency of integration of enterprises in the framework of globalization and of the variety of economic relations of producers in the modern market. Integration processes are typical for a market economy that seeks to minimize costs to maximize profits. The authors present the characteristics of the integration with regard to its determination into property. Also the characteristic of globalization, on essence and the contents similar to integration is given. The authors consider the factors of integration in the global world, the impact of which limits the growth of integrated systems, regardless of whether they are built within a single enterprise or within other different economic entities, including interstate integration. The authors believe that the limit values characterize the process of integration, including the dynamics of marginal utility and the dynamics of decreasing productivity are equally applicable to describe the models of integration growth. On the basis of the Gauss model and the theory of fuzzy sets, a model of the marginal efficiency of integration with the construction of the author's model for assessing the consequences of integration growth that are not comparable in physical units is proposed. The authors show the optimal point of integration in the context of globalization and a model for assessing the degree of monopolization of the company as a negative result of integration.

1 Introduction

The question of whether large-scale integration in the framework of growing globalisation is topical, since any cooperation, including in the form of integration not only increases productivity and profits, but also leads to the monopolization of activities of the enterprise in a particular sector and a particular territory. We consider the limits of effective integration of enterprises in the context of globalization and identify the risks of such integration.

Literature review

On the topic of enterprise integration, there is a large number of studies by Russian and foreign scientists of both past centuries and modern times.

The methodology and essence of integration was studied in the works of foreign authors: G. Hegel, K. Marx, G. Spencer, T. Veblen, D. North, and also such Russian researchers as G. D. Antonov, V.V. Gavrilov, T. P. Korotkov, O. V. Osipenko, K. Portnoy, N. Yu. Psareva, I. S. Shitkina, Yu. V. Shishkov, L. V. Shulgina, V. A. Engelhardt, I. P. Yakovlev.

M. G. Dikansky and V. A. Shildkrut considered the activities of integrated structures in the global economy [1–16].

Main part

We consider the integration of economic structures as the relations of owners regarding the merging of property rights to limited production resources established by force or power, in order to effectively manage these resources and minimize market risks for the free development of owners. Moreover, integration in the economic sense is precisely the relationship of business entities regarding property relations in the case of three levels: full independence (closed system)—economic relations (partially open system)—loss of independence in the integration process as a form of merging of property (full synthesis, open system).

Globalization in the innovative stage plays the role of a factor that largely determines the forms and directions of integration processes. By globalization, we mean the large-scale, cross-country formation of a monoculture based on innovative developments of consumer preferences and new types of products and services by transnational corporations as opposed to ethnic traditional cultures. Globalization contributes to new forms of integration in accordance with processes of an interstate scale that influence the macroeconomic and microeconomics of a particular country.

Integration in the economic sense represents a variety of relationships between economic entities regarding property relations that contribute to their income effect in the context of globalization.

However, the category "globalization" itself is similar in content to the category "integration", since in the process of globalization, not only industrial enterprises, but also state economic systems are United, and public-private relations are formed.

Global integrant enterprises displace smaller ones from the market, determine the conditions on the labor market, form their own pricing policy, despite a number of antitrust laws, and actually dictate their own economic conditions.

Modern economic realities show that when an economic entity accumulates a "critical monopoly mass", it becomes not the flagship of the country's economy, but its anchor. Giant companies with a global network of branches tend to lose their efficiency and management structure. This has an extremely negative impact on the results of the company itself, breaking its image and creating chaos in the economic environment where it operates. We should also not forget about the strict sanctions policy, the effect of which was fully felt by many of the largest enterprises and the country's economy as a whole.

In this regard, a method is proposed that allows one to determine the ultimate level of integration that will bring maximum effect both for the enterprise in particular and for the country's economy as a whole.

The concept of marginal profitability is known when, when using an additional unit of a certain factor, an increment of the positive effect occurs. But this increment does not increase infinitely, but has an asymptotic limit. This happens with giant enterprises when the economies of scale cease to work and have a positive effect, and the law of diminishing returns begins to work.

In this task, the most difficult is the issue of identifying and evaluating the parameters of the globalization of the system. How, for example, to assess the degree of monopolization or the level of manageability of a company with the status of a concern? Table 1 presents general criteria that allow giving a basic description of the integration process in the context of globalization.

He set of factors can be expanded as part of adapting the task to real economic conditions: country, region, industry, concern, etc.

Let's consider the impact of these factors on the economy at various stages of the globalization process. Thus, at the stage of economic growth, as a rule, there is a positive effect. Jobs are created, which makes it possible to talk about reducing the unemployment rate, the company is growing and developing, the market share is increasing, etc. But this process is not infinite in its positive manifestation. If there is further globalization, we see the manifestation of negative factors of the process. Smaller businesses that cannot compete with the giant companies are being pushed out of the market, and many of them are going bankrupt, leaving people out of work.

Speaking about the quality of products, works, services, it should be noted that at the growth stage a large enterprise, conquering the market, as a rule, takes this indicator to the maximum level, which can be done by the resources of the enterprise. But the growth stage is slowing down. A large market share is dominated by a large company. As practice shows, during this period the enterprise, which is practically a monopolist, does not need to conduct intense competition for quality, for the consumer, for a place in the market. The manufacturing giant begins to dictate terms to partners.

Table 1 Factors of the integration process

Positive factors	Negative factors
Creation of large production systems	Monopolization of the manufacturing sector
Formation of industrial and economic relations (vertical and horizontal), optimal infrastructure	Decreased company manageability Bulky organizational structure, confusion of functions
Quick solution to social problems of workers	Optimization of the number of employees, crowding out small and medium enterprises from the sector (growth of unemployment)
Reducing production costs by optimizing infrastructure	The formation of a monopolistically high price
Product quality growth (at the initial stage)	Lower product quality(in the stage of monopolization)
Market segment expansion	Full market capture
Perfection and development of production, use of innovations	Slowdown due to lack of competition, creating barriers to innovation, competitive business monopolies
The growth of income and profits	Monopoly high profit growth due to monopoly high prices

The task arises of determining the stage of globalization that is most effective for the economy, when only positive factors of growth and development dominate, that is, before the stage of monopolization with all the ensuing negative consequences for the economy as a whole.

In general, the model for assessing the marginal efficiency of the integration process can be represented as a Gaussian membership function (Fig. 1).

$$\mu = e^{\left[-\frac{(x-a)^2}{ba^2}\right]},$$

where

a the coordinate of the maximum membership function;

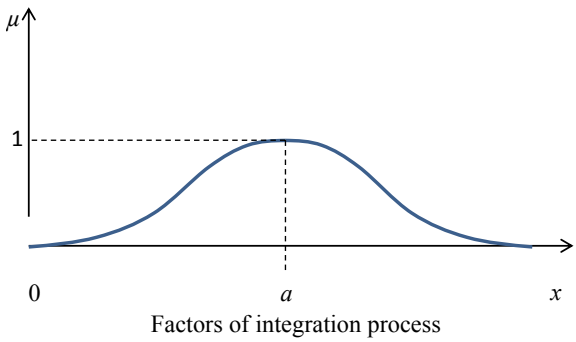

Fig. 1 Graphic model for assessing the marginal efficiency of the integration process in the context of globalization

b the coefficient of concentration of the membership function

Factors are located along the Ox axis, the growth of which leads to a positive economic effect at the macro level during the growth period of the process and gradually reduces the positive result when passing the critical maximum of factors indicated in Figure a. The membership function ranges from 0 to 1.

The complexity of the statement of the problem is that the factors listed in the table are sometimes not amenable to numerical expression. In this case, we use the universal mechanism of the theory of fuzzy sets (hereinafter TFS), which allows us to evaluate objects of non-numerical nature. Moreover, these models make it possible to evaluate disparate parameters by expressing them through a system of coefficients. In addition, the proposed model allows a number of non-numeric parameters to be expressed through a point system on an n-point scale.

Consider an example. Suppose a set of factors has been identified that determines the degree of globalization of the company. Our task is to identify how monopolized the company is, which will allow us to make the proposed point estimate, since a number of factors are difficult to express through numerical parameters. In this case, it is more convenient to use the method of expert assessments. Let the criteria be evaluated expertly on a 10-point scale (Table 2).

Based on these expert assessments, it can be said that this is a large enterprise that is developing successfully, while there are clear signs of monopolization of the company. Those processes are taking place that, ultimately, will play a negative role on a general economic scale. Obviously, the company almost completely captured the market. Competition at the lowest level. The monopolization process has started. But for the company also negative aspects are revealed. There is no need to talk about high rates of production growth, the qualitative characteristics of products (goods, works, services) also have very insignificant positive changes, the dynamics of the enterprise's income is mainly due to market volumes. But the most unpleasant phenomenon for a global company is the loss of controllability. The presence of a wide network of branches and subsidiaries creates its own difficulties. Therefore, those factors that were clearly positive in the period of the company's growth now negatively affect both the economy as a whole and the enterprise itself. It remains to determine how the company is on the verge of accumulating a "critical mass" in terms of monopolization.

Based on (1), the calculation of membership functions for each criterion was performed (Table 3).

The integral coefficient determines whether the enterprise belongs to the critical interval based on a set of factors.

Graphically, the model is shown in Fig. 2.

Based on the calculations, it is clear that the enterprise is on the verge of a critical monopolization zone. Further growth of the company in the direction of conquering the market, crowding out the remaining few competitors will lead to complete monopolization.

Table 2 Expert assessment of criteria on a 10-point scale

Criteria for evaluation	Levels of monopolization									
	Low			High				Ultimate		
	Rating scale, point									
	1	2	3	4	5	6	7	8	9	10
Creation of large production systems							+			
Formation of industrial and economic relations									+	
Solving the social problems of workers								+		
Product quality growth				+						
Market segment expansion									+	
Perfection and development of production					+					
The dynamics of enterprise income growth				+						
Enterprise Growth						+				
Company Management Efficiency			+							
Reduction of small and medium-sized enterprises (increase in unemployment)								+		
Competition		+								

2 Conclusions

The model is presented on some conditional example, but, solving a specific problem for individual industries or giant enterprises that determine the economic policy of the regions, and sometimes the country as a whole, it is necessary to adapt a set of factors directly to real conditions. The model can be changed in quantitative and qualitative criteria selection, numerical indicators can also be applied, which will greatly facilitate the assessment. The point scale in the case of application can have

Table 3 Indicators of the membership function for each criterion

Electronic and Digital Tools for Neo-Industrialization in the Contract Relations Arising from Public Procurement of Economic Entities of the EAEU Countries

Agnessa O. Inshakova, Iolanta V. Baltutite, and Svetlana Yu. Kochetkova

Abstract **Introduction** At the moment, a significant period of time has passed since the Russian Federation (hereinafter referred to as the RF) embarked on the path of democratic transformation, which has made the significant adjustments to all spheres of the state's life. Currently, the RF is actively developing market relations and market principles of procurement; the planned economy and the command-administrative relations which regulated it have already been left in the distant past. In the context of Russia's economic development and financial stability, it was necessary to create a quality mechanism for distributing and regulating trade in the country. In this case, an effective "tool" was the contract procurement system with all its components, which allowed the national economy to reach a new modern level of development. The rapid development of digital technologies in the world leads to an intensive transformation of the entire system of public relations. The technological changes also require greater flexibility in the procurement system. Now we can see how the traditional methods of conducting the procurement procedures are increasingly taking a back seat, giving way to the electronic procurement procedures. Under the influence of these processes, the system of public procurement in the Eurasian Economic Union began to develop. **The purpose of the work**: to study the characteristics, value, the positive aspects of the methods of selecting the executors of the order by e-environment in the contract procurement system of Russia, the state procurement of economic entities in the countries of the EAEU, the information support of the contract procurement system in Russia and the EAEU countries; to identify the existing problems in the contract purchasing system on the EAEU market; to study and adopt the foreign experience in electronic procurement. **Methods**: the methods of systematicity, analysis, and comparative law are used. **Results**: the authors' well-founded position is based on the legislation and the opinion of the scientific community on the current opportunities for electronic and information support of the contract procurement system

in the EAEU. For a systematic and practical update of the legal rules governing the electronic procurement procedures, as well as the overall unified procurement information system, it is necessary to create an initial legislative base from which in the future, it would be possible to start, change and supplement it, adhering to a gradual approach, rather than a cardinal one. The international experience in the implementation of public procurement in various countries shows the missing points in the Russian contract system, as well as provides for the introduction of new methods and approaches to the organization of relations in public procurement in the EAEU countries. **Conclusion**: the existence of a unified procurement information system, electronic platforms, and electronic procurement undoubtedly contain a number of positive aspects: the level of competition increases, the price to be paid from the budget is lower, the interference in the relevant procedures of the commission members is reduced, the corruption risks and the risk of collusion are drastically reduced, and the entire procurement process is more transparent. Public procurement is an important part of the economic structure of the EEU member states. In this regard, it is necessary to remove the obstacles in the internal market of the union. There are a number of issues and areas that the countries still need to work on. At the same time, the experience of foreign countries and the EU countries considered by the authors in the paper is very tempting, but it is not necessary to blindly adopt all the possibilities of the world's electronic and information procurement systems.

1 Materials

The legal framework for the study is made up of the normative legal acts, their projects, as well as various documents of a programmatic nature. In particular, one of the strategic directions for the development of this state, outlined in The Strategy for the Development of the Information Society in the Russian Federation for 2017–2030, is to build a competitive economy, which can be achieved, including through the implementation of the national projects aimed at creating the digital economy. In addition, during the research, the authors referred to the provisions of such legal acts as: The Treaty on the Eurasian Economic Union dated 29.05.2014. [1]; Letter of the Ministry of Economic Development of Russia dated 20.03.2017 No. D28i-1393. The Ministry of Economic Development of Russia. Decree of the Government of the Russian Federation of 16.09.2016 No. 925 "On the priority of goods of Russian origin, works, services performed, provided by Russian persons in relation to goods originating from a foreign state, works, services performed, provided by foreign persons" [2]; Order of the Ministry of Finance of the Russian Federation of 04.06.2018 No. 126n "On the conditions for admission of goods originating from a

foreign state or group of foreign states for the purpose of purchasing goods for state and municipal needs" [3]; Decision of the Supreme Eurasian Economic Council of October 11, 2017 No. 12 "On the main directions of the implementation of the digital agenda of the Eurasian Economic Union until 2025" [4].

The theoretical basis of the study is made up of the works of the Russian researchers, whose works address certain issues related to the introduction of digital technologies in the public procurement contract system (Baltutyte I. V., Davudov D. A., Goncharov I. A., Inshakova A. O., Kofner Y. A., Tebekin A. V., Marchukov I. P.).

2 Methods

In the study, the authors used the general scientific methods, including dialectical, inductive, deductive, analytical, synthetic, and prognostic ones, and the specific scientific methods, such as formal legal, the method of legal interpretation, the principle of evaluating legal processes, and others.

3 Introduction

Currently, the regulatory block of legislation regulating the public relations in procurement has completely changed. The state and municipal authorities are becoming active participants in the economic turnover, building numerous equitable economic relationships with other economic entities on a daily basis. The changes made to the legislation on the contract system, which regulate the gradual transition to the implementation of procurement procedures and the conclusion of contracts exclusively in electronic form, indicate that there is a tendency to digitalize the sphere of public procurement.

Among the main approaches and principles of the modern Russian contract system are: improving the efficiency and effectiveness of procurement, preventing corruption and its manifestations, as well as the abuse at each stage of state (municipal) procurement. It should also be noted that a system of monitoring, audit and control of purchases has been established to date. Such a complex system fully fits into the principles of achieving efficiency, which are guided by the Russian legislator.

In recent years, there has been a significant development of digital technologies that have had a huge impact on all aspects of the daily life of the state and society, including public procurement.

4 Reforming Public Procurement in the Framework of the EAEU

Today, there is a tendency to widely use information technologies in the world, using modern advanced computer systems, and public procurement is no exception. At the moment, this process is actively developing in two main directions. First, the internal processes are computerized—e-procurement modules and Supply Chain Management are introduced. Secondly, the external resources—electronic trading platforms—are actively used [5].

The current document—the Strategy for the Development of the Information Society in the Russian Federation for 2017–2030 fixes [6]:

(a) accessing the electronic forms of commercial relations for small and medium-sized businesses;
(b) promoting the introduction of electronic document management in the organizations, creating the conditions for increasing confidence in the electronic documents, and performing the electronic identification and authentication of participants in the legal relations;
(c) reducing the administrative burden on business entities due to the use of information and communication technologies.

In order to develop the economic cooperation and expand trade and economic ties, information technologies, the effective functioning of a free trade area, and create the conditions for the free movement of goods and services, the draft Protocol on Procurement Rules and Procedures among Parties to the Treaty on a Free Trade Area [7] was approved in 2016. In 2017, the President of the RF signed a law ratifying this Protocol [8]. The Protocol sets out the goals, the principles of regulation and the requirements in public procurement, including the requirements for the organization and pursuit of electronic procurement. At the same time, a phased implementation of the Protocol is provided:

– until January 1, 2018, the process of changing the procurement legal framework of those states that signed the Protocol should be carried out (in particular, this is related to the procedure for making purchases in electronic form);
– until January 1, 2019,—to develop and use the information technologies that contribute not only to the transparency of procurement, but also to the compatibility of the information bases and programs of the countries participating in procurement activities.

Due to the historically close relationship between the post-socialist countries, state (municipal) purchases are currently one of the key areas that influence the mutual trade under operation of the internal EAEU market.

The changes to the Russian contract system relating to electronic procurement were directly influenced by the provisions of The Treaty on the Eurasian Economic Union, which provide for the need to ensure the unhindered access of the participants and the participants of member states to participate in the procurement procedures

conducted in electronic format by the mutual recognition of an electronic digital signature made in accordance with the legislation of one member state by another member state (The Agreement on the Eurasian Economic Union of May 9, 2014). The introduction of the provision on electronic procurement is certainly a significant step towards bringing the legislation of the RF closer to the legislation of the EAEU countries and ensures the implementation of the provisions of the above-mentioned Treaty.

On October 1, 2017, the EAEU countries approved the main directions of the digital agenda of the Union until 2025 (The Decision of the Supreme Eurasian Economic Council of October 11, 2017 No. 12). The areas of development of the digital economy in the framework of this document include:

– the digital transformation of the economic sectors and cross-industry transformation;
– the digital transformation of goods, services, capital and labor markets;
– the digital transformation of management and integration processes;
– the development of the digital infrastructure and ensuring the security of digital processes.

This document is important for the EAEU member states in the framework of developing the integration, strengthening the common economic space and deepening the cooperation between the member states.

In addition, from the beginning of 2018, the economic entities from the Union countries can participate in procurement procedures on an equal basis with the Russian ones. In the same year, the Eurasian Intergovernmental Council approved the order "On the formation of a high-level working group on cooperative integration interaction and import substitution in priority industries". The working group is being created to develop common approaches to implementing the cooperation and import substitution projects in the EAEU.

The current order of the Ministry of Finance of the RF provides the price privileges to the participants of public procurement who offer deliveries from the list of goods of Russian, Armenian, Belarusian, Kazakh and Kyrgyz origin in their applications. According to the order, if a participant offering goods from the EAEU member states wins the procurement, the contract will be concluded at the price offered by him. For the suppliers of foreign goods, if they win, less favorable conditions are provided—a 15% reduction in the contract price (The Order of the Ministry of Finance of Russia of June 4, 2018 No. 126n).

In the near future, the representatives of the EAEU countries will be able to participate in the Russian public procurement procedures in defense and security.

Recently, the issue of creating a cryptocurrency for mutual settlements between the EAEU countries has been discussed. To do this, first of all, it is necessary to form the concept of a common financial market, which should be launched in the EAEU in 2025. The central (national) banks are developing this concept.

According to A. V. Tebekin, the significant problems in the development of an effective economic mechanism for regulating public procurement within the EAEU

include the significant lagging in the level of economic development of the Union member states behind the world leaders [9].

Due to the existing economic ties between the states, the legal harmonization, unification and coordination of the state legislation are necessary measures not only in terms of building a single legal framework, but also in order to approach the norms of international law [10].

The experience of various countries in public procurement is of great interest for improving the methods of organizing purchases in Russia, as well as in Russia's relations with the EAEU countries.

For the successful development and improvement of the Russian contract system, it will be "useful" to refer to the international experience of state order planning. Thus, the American Federal Contract System (hereinafter-the US FCS), in which, according to the statistics, every fifth order occurs with a smaller share of violations is developed most of all. In the United States, there are many information resources for the FCS, which ensures the implementation of the principle of transparency and openness. In 1994, the law on improving the Federal procurement system appeared in the American legislation; it became the basis for modernizing the information resources and using the electronic services in the system.

Currently, all the U.S. Federal agencies are required by law to enter the information about non-classified contracts that cost more than $ 25,000 into an electronic computer database over the past five fiscal years. And then they must transmit this information to the Central Information System of Federal Procurement.

In the United States, customers are required to post purchase notices on the publicly available government websites (as opposed to purchasing plans). Customers should post the information about the contracts on their website and send it to the Federal Department of Purchasing Policy. The office itself determines what information should be placed in the Federal Register.

In Germany, the selection methods of procurement are provided, which, in turn, means the selection of participants in public procurement by the specialization and organizational and legal forms of legal entities.

In some countries, the information about purchases is posted on two or more sites. For example, there are two main procurement sites in China. At the same time, the second site differs from the first one in that it contains more official information, including statistics, a larger number of regulatory documents than on the first site, theoretical research, and even the ability to ask questions about procurement of the government officials.

South Korea also has two procurement sites: a platform for public procurement, and a platform for private procurement. Private purchases carried out on the platform for private procurement are different from the state one in less regulation and more freedom of customers to establish the rules for pursuing the procurement.

In Australia, the national strategic program for automating all technological stages of the competition for the supply of goods for public needs is being implemented. There is an information and reference system; the legal and other documents related to electronic bidding are released over the Internet, and the electronic processing, registration, management and payment of contracts are available.

The positive practices of foreign countries should also be used in Russia:

– the availability of the legal principles such as transparency of competition (USA) and the selection methods for determining suppliers (Germany);
– the creation of a centralized and decentralized model of procurement relations in Germany. The centralized contract system means that all applications for the participation in purchases are sent to a special reception center, where they are checked. The decentralized form of the contract system is that different levels of government agencies make purchases through the special procurement departments and offices, which greatly simplify this process;
– the opportunity to ask a question about procurement of the government officials (PRC).

On October 1, 2018, Dmitry Medvedev signed "The Main Activities of the Government of the Russian Federation for the period up to 2024" [11]. This document also points to the need for the development of digital technologies in public administration, the legislative regulation of the formation and maintenance of the state information resources, the establishment of rules for the information systematization in these resources, as well as the harmonization of information between various information resources of the public authorities.

In addition, the document stipulates the measures aimed at developing the contract system in procurement of goods, performance of works and provision of services for the state and municipal needs; the measures to introduce digital technologies and platform solutions ("digitalization") in the practical activities of the federal, sectoral and regional government bodies, including:

– cataloging purchased goods, works, and services;
– transferring the procedures for determining the supplier (contractor) into electronic form;
– ensuring the transparent pricing when making purchases at the expense of the budget funds by disclosing by the supplier (contractor) the price structure of the state contract, keeping separate records of the results of its execution and creating the conditions for a gradual transition to the regulation and setting a limit on the profitability of works and services purchased for the state needs;
– simplifying the mandatory procedures for customers and the procedure for their interaction with procurement participants when rationing, planning, preparing and reviewing applications, and concluding contracts.

In order to form a common public procurement market and improve its work towards transparency, Russia and the countries of the Eurasian Economic Union can study the experience of the European Union, whose activities in this area are much more advanced.

In the field of procurement in the EU as a whole, there are three main areas of the legislation development: first, the broadening of powers of the customer when choosing the procurement procedures and determining the winner of the purchase; second, detailing the rules at all stages of procurement; and third, converting the document flow in procurement into electronic form.

An innovative partnership should be considered a relatively new and promising way of purchasing in the EU. Purchasing through the formation of an innovation partnership is allowed for products that cannot be purchased in the available markets. The customer decides to create an innovative partnership with one or more partners who carry out separate research activities [12]. In our opinion, the introduction of such a method of procurement would be very useful.

The most important element of any procurement system is its information openness.

Each country has its own source of publication of the procurement reports; as a rule, it is the Internet site. For example, in Russia, this site contains information about both state (municipal) purchases and corporate purchases. The functioning of the unified information system is also ensured by the operation of eight electronic platforms and one specialized electronic platform [13].

According to the Treaty on the EAEU, the information openness and transparency of public procurement should be ensured. Currently, the information is published on the national web portals of the EAEU member states, but there is no unified database, of course. In this context, the EU experience is interesting. As an example of the availability and transparency of the procurement sphere, we can use the unified TED database (Tenders Electronic Daily), where you can view, search and categorize the procurement notifications by country, region, business sector, type of goods and services, and other criteria [14]. In the EU, all procurement documents, including the terms of the contract, must be available on the Internet from the publication date of the notification in the Official Journal of the European Union (OJEU). The contracts whose price exceeds the European level must be published both in the national database of the EU country and in EU's Tenders Electronic Daily.

As a rule, third parties have unrestricted access to the procurement information sources in all countries, and no fee is charged for using the information from these sources.

5 Conclusion

Developing the planning system and legal regulation of public procurement in this country, you need to equally use both your experience and the experience of foreign countries, and also consider the implications of the practical application of the innovative methods in order to achieve the ultimate goal of the management of government procurement—improving the efficiency, proper performance and transparency of state orders.

We can safely say that public procurement of goods, works, and services for state and municipal needs is a structure in demand in the modern economic and legal system of Russia, which is confirmed by the constant growth in the volume of financing in the contract procurement [15].

The digitalization in trading, in our opinion, has a number of positive characteristics and should be considered as an undoubted achievement. However, like any other

change, digitalization brings certain risks to the trading sphere. This leads to the fact that one of the most important tasks is the timely assessment of various achievements of digitalization used in the bidding process, and the correct legal qualification of unfair practices in this area, as well as the development of mechanisms for responding to such "digital" attacks on the interests of competition.

Despite the positive nature of the changes in the contractual relations between the EAEU countries and Russia, the level of mutual participation in public procurement in the EAEU remains low. It should be noted that, due to the largest size in the monetary terms of public procurement, implemented by Russia, it is clear that, first of all, the rest of the member states of the Union who have access to this large market stand to gain from the formation of a single Union market in this area.

Public procurement is an important part of the economic structure of the member states; therefore, it is necessary to remove the obstacles in the internal market of the Union. One of the problems in studying the EAEU public procurement market is the lack of its comprehensive statistical accounting and analysis.

Currently, one of the key areas on which the EAEU and Russia need to work together is:

– ensuring the mutual recognition of an electronic digital signature;
– ensuring the mutual recognition of the bank guarantees in public procurement;
– creating a single electronic public procurement platform in the EAEU;
– ensuring the control over the origin of goods offered on the Union procurement market, including the use of electronic technologies.

In the future, it will be appropriate to agree on various preferences and benefits for the applications that provide a certain share of industrial cooperation between the enterprises of the member states of the Union.

The participation in the common procurement system, together with the EAEU countries, each of which intends to defend its national interests, as well as the process of digitalization of the market, will necessarily lead to the increased transparency and professionalism of the entire system. These factors will eventually lead to a reduction in corruption, which will have a positive impact on the entire procurement system in the EAEU.

The system of public procurement in the EAEU is reaching a new level, and as the countries continue to interact and the EAEU authorities make decisions, it will go on improving.

Innovations vs. Traditions: Notion, Essence, and Opposition Depending on Economic Systems' Financial Position

Alexey V. Tolmachev, Juliana A. Kitsai, Olesya V. Belaya, and Zaur Aliyev Patlaze

Abstract Purpose: Solving the problem of uncertainty of the economic consequences of the traditional and innovative societies, which hinders justified decisions in the sphere of traditions and innovations during state and corporate management, through specification of the economic essence and notions of innovations and traditions, as well as opposing traditional and innovative societiees from the positions of economic consequences depending on the economic systems' financial position. Design/methodology/approach: Comparative analysis and correlation analysis are used for finding the differences in the value of the Global Competitiveness Index 4.0, happiness index, and sustainable development index, as well as differences in their correlation with the Global Innovation Index in innovative economies (developed and developing countries with the highest values of the Global Innovation Index) and traditional economies (developing countries with low values of the Global Innovation Index). The research is performed based on the data as of early 2020. Findings: The authors find substantial differences in the consequences of innovations management in the traditional and innovative economies by the level of The Global Competitiveness Index 4.0, level of society's happiness, and sustainability of development depending on the economic systems' financial position. Also, differences in dependence of these characteristics on innovations management are found. Originality/value: It is determined that innovations in economics (unlike other socio-humanitarian sciences) are not directly opposite to traditions, but have a lot of

1 Introduction

The scientific concept of innovations is built on their difference from traditions. In a general sense, traditions always mean the foundation on the existing experience, and innovations suppose something new. Such simple definitions allow differentiating social systems and distinguishing traditional societies—which oppose globalization and preserve their uniqueness, and innovative societies—which are ready for constant changes and lose their uniqueness under the influence of globalization, for expanding their presence in external markets.

From the positions of the most socio-humanitarian sciences (e.g., social sciences, culture studies, and law), the above definitions are informative and actual, as they clearly show the social (social isolation and globalization), cultural (preservation of historical cultural heritage or modernization of culture, merging of cultures), and legal (bans and limitations on international trade, international movement of production factors, and cooperation communications—or their support) consequences of assigning society to a certain type according to the given classification.

However, from the positions of economics the existing definitions are not sufficient—as they do not reflect the economic consequences of the selected public mode (which are contradictory). On the one hand, innovative society has a large potential in solving socially important tasks by using the leading technologies and ensures high competitiveness of domestic companies in the global markets by means of technological advantages. It is also necessary to note generally known advantages of free-trading, as compared to protectionism. On the other hand, traditional society has fewer social commotions and allows preserving a harmony of society and environment and preserving uniqueness of competitive advantages.

The uncertainty of economic consequences of traditional and innovative societies hinders the justified decisions in the sphere of traditions and innovations during state and corporate management—which is an important scientific and practical problem of modern times depending on the economic systems' financial position.

2 Materials and Method

Innovations, their role and meaning in functioning and development of development of economic systems, and differentiation of traditional and innovative economies are studied in the works [2–6, 8, 9, 22, 27].

Specifics of innovations in the modern context of formation of the innovative economy (knowledge economy), digital modernization, and transition to Industry 4.0 are studied in the works [1, 10–21, 23–26, 28].

We see that the main attention in the above works is paid to qualities (characteristics) of the traditional and innovative economies, tendencies and perspectives of their development, and causes of development of economic systems within a certain model. The consequences of implementing the model of the innovative and traditional economies are studied poorly and require further elaboration [7].

Comparative analysis and correlation analysis are used for determining the differences in the values of the Global Competitiveness Index 4.0, happiness index, and sustainable development index, as well as the differences in their correlation with the Global Innovation Index in countries with favorable financial position (with high values of the Global Innovation Index) and countries with unfavorable financial position (with low values of the Global Innovation Index). The research is performed based on the data as of early 2020 (Table 1).

3 Results

The results of systemic analysis of the economic consequences of innovations management in innovative (stimulation) and traditional (restraint) countries in 2020 are shown in Figs. 1, 2 and 3.

As shown in Fig. 1, the Global Competitiveness Index 4.0 of innovative economies is 1.55 times higher as compared to traditional economies. In both categories of countries, The Global Competitiveness Index 4.0 is almost fully explained by the values of their Global Innovation Index: correlation in innovative economies equals 98%, and in traditional economies—95%. Therefore, limitation of the innovative activity in traditional economies hinders the provision of their global competitiveness.

As shown in Fig. 2, the level of happiness of innovative economies is 1.45 times higher as compared to traditional economies. In innovative economies, the level of happiness is by 79% explained by the value of their Global Innovation Index, and in traditional economies—only by 36%. Therefore, innovative economies depend on their innovative activity, and its restraint leads to reduction of the happiness level in society. Traditional economies are less susceptible to their innovative activity, and the society's happiness level in them is mainly determined by other reasons, which are not connected to innovations. Due to this, traditional societies can keep up a stable level of happiness, while innovative economies are susceptible to higher cyclicity—each decline of the innovative activity might lead to a social crisis.

Table 1 Statistics of innovations and their hypothetical consequences в developed and developing countries in 2020

Financial position	Country (by decease of the global innovation index)	The global competitiveness index 4.0, points 1–100	Global innovation index, points 1–100	Happiness index, points 1–100	Sustainable development index, points 1–100
		a	*b*	*c*	*d*
Favorable	Switzerland	82.3	67.24	7.480	78.8
	Sweden	81.2	63.65	7.343	85.0
	USA	83.7	61.73	6.892	74.5
	Brazil	60.9	33.82	6.300	70.6
	India	61.4	36.58	4.015	61.1
	Russia	66.7	37.62	5.648	70.9
	On average	72.70	50.11	6.28	73.48
Unfavorable	Rwanda	52.8	27.38	3.334	56.0
	Nepal	51.6	24.85	4.913	63.9
	Nigeria	48.3	23.93	5.265	46.4
	Cameroon	46.0	23.90	5.044	56.0
	Zambia	46.5	20.36	4.107	52.6
	Yemen	35.5	14.49	3.380	53.7
	On average	46.78	22.49	4.34	54.77

Source Compiled and calculated by the authors based on Institute of Scientific Communications (2020)

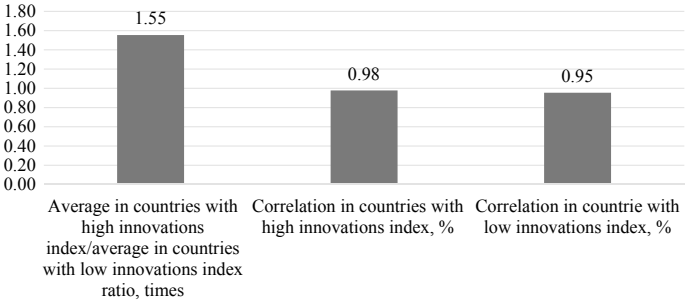

Fig. 1 Difference in the Global Competitiveness Index 4.0 of countries with different financial positions in 2020. *Source* Calculated and compiled by the authors

As shown in Fig. 3, sustainability of development of innovative economies is 1.34 times higher as compared to traditional economies. In innovative economies, sustainability of development is by 80% explained by the value of their Global Innovation Index, and in traditional economies—only by 24%. Therefore, innovative

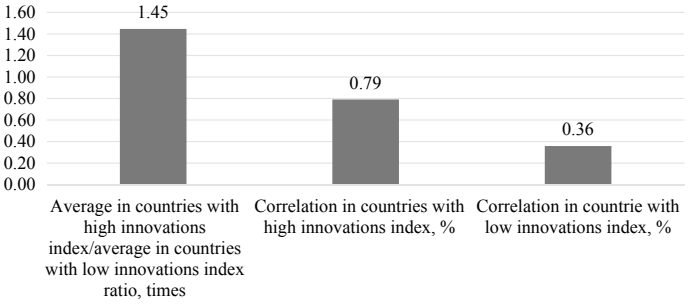

Fig. 2 Difference in the level of happiness in countries with different financial positions in 2020. *Source* Calculated and compiled by the authors

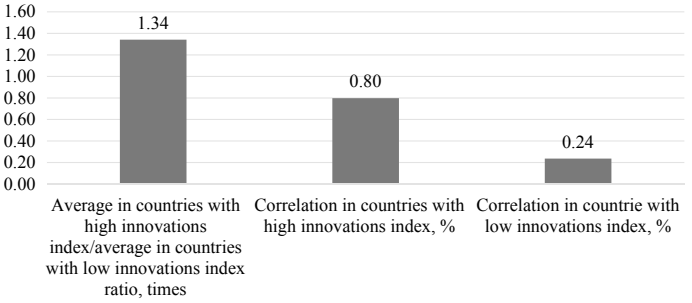

Fig. 3 Difference in sustainability of development of countries with different financial positions in 2020. *Source* Calculated and compiled by the authors

economies are based on the opportunities of technological progress during provision of public well-being and environment protection.

However, in a lot of cases "green" innovations have to soften the negative consequences of technological progress—in particular, prevent the energy crisis as a result of digital modernization. Depletion of the innovative potential of the technological mode hinders sustainable development and might cause ecological crises. Traditional economies use other—not-technological—opportunities of sustainable development. The sole refusal from industrialization and neo-industrialization stimulates environment protection.

4 Conclusion

Thus, the determined significant differences in the consequences of innovations management in countries with different financial position allow for the following conclusions:

– Innovations in economy (unlike other socio-humanitarian sciences) are not completely opposite to traditions, but have a lot of common features. In particular, traditions and innovations are strategic tools of state and corporate management of development of socio-economic systems;
– Innovations are new knowledge and technologies, as well as institutions of their creation, dissemination, and implementation, which support and are a mandatory condition of normal functioning of innovative economies' development; however, they are not required by traditional economies. The essence of innovations consists in supporting the eocnomy's global competitiveness. However, it is more required by globalized innovative economies than by internally-oriented or even closed traditional economies;
– traditions are social institutes that are not subject to changes and that are preserved even if they lose their effectiveness—i.e., transform into "institutional traps". The essence of traditions consists in the fact that dependence on them hinders the provision of global competitiveness of traditional economies, but, at the same time, ensures their expanded and flexible possibilities for increasing society's happiness and sustainable development;

It should be concluded that both models of innovations management—traditional and innovative economies—are viable and effective in the modern economic conditions, each of which has its advantages and drawbacks. Selection of a model should be determined by the economic system's financial position. The established differences in the level of The Global Competitiveness Index 4.0, level of happiness, and sustainability of development require further thorough research. It seems that innovations management depending on financial position is not the only and the main reason of differences between these categories of countries—this issue should be studied in further works.

The Conceptual Approaches to Studying the Influence of Country's Financial Position on Its Innovative Activities and the Paradigm Modern Treatment

Alexey V. Tolmachev, Irina I. Klimova, Jolita Polishkene, and Zifa H. Nizametdinova

Abstract Purpose: Systematizing the existing conceptual approaches to studying the influence of a country's financial position on its innovative activities and compiling the paradigm modern treatment. Design/methodology/approach: Correlation analysis is used for determining the consequences of innovations in all considered aspects and for determining the differences between developed countries (by the example of the OECD countries with the highest values of the Global Innovation Index) and developing countries (by the example of BRICS countries as the most progressive countries) in 2020. Findings: The results of the performed research show that the existing conceptual approaches to study of innovations are correct and reflect different aspects of innovations. However, there are substantial differences between developed and developing countries, which show that the consequences of innovations are largely determined by the financial position of the country in which they are performed. Originality/value: It is proved that the quality of innovations that is connected to their ability to be a mechanism of crisis management (not found in developed or developing countries) cannot be considered a universal characteristic of innovations and should not be included into their basic definition; it is a separate case, which is observed in a strictly specified context. A paradigm modern treatment of innovations is offered—it reflects their universal qualities, proved in the course of the research, and conditions during which they are observed.

1 Introduction

Innovations play a very important role in the modern world, determining humankind's ability for survival. Innovations are the basis of adaptation to the changes of the environment of any type—ecological, socio-cultural, and economic. From the scientific point of view, significance of innovations is explained by the following reasons. 1st reason: the evolutional form of organization of economic systems, in which new inventions and technologies, as well as ability for their generation and usage, are the highest value is called the innovative economy, also known as the "knowledge economy".

2nd reasons: susceptibility to innovations is a popular criterion of societies' classification. By this criterion, we distinguish society that negatively treats any changes and protests against innovations, and society that supports innovations and creates and uses them. 3rd reason: innovative policy is an independent and mandatory direction of state regulation and corporate management.

Complexity and the multi-aspect character of innovations complicate their scientific definition. The etymology and logic of treatment of this term show that it means creation (in the process of targeted R&D or random creation of know-how), dissemination (registration of intellectual property rights and their transfer), and usage (implementation into economic practice) of something new—knowledge or technologies. At the same time, the consequences of innovations are diverse and are studied within a lot of conceptual approaches to treatment of the economic essence of innovations.

On the one hand, this allows for detailed study and description of each consequence of innovations. On the other hand, this causes a problem of absence of a general scientific definition of innovations that would cover all its aspects, including the least studied financial aspect. The purpose of this work is to systematize the existing conceptual approaches to studying the influence of country's financial position on its innovative activities and to compile a paradigm modern treatment.

2 Materials and Method

Literature overview allowed determining four conceptual approaches to studying innovations as the objects of economic research. The first approach focuses on the micro-economic aspect of innovations and treats them as a direction of entrepreneurial activities that is connected to high risk of investing and usage of

resources. This approach is presented in the works Andronova et al. (1), Belik et al. (3), Haabazoka (6), Popkova et al. (17), Shulus et al. (23), and Stolyarov et al. (24).

Within the second approach, scholars focus on the macro-economic and international aspect of innovations, which are studied through the prism of cyclic fluctuations of economic systems. Innovations are treated as a tool of crisis management, and it is acknowledged that innovations could cause crises—if high level of risk leads to formation of "economic bubbles". The representatives of this approach include Atkinsonk and Ezell (2), García-Quevedo et al. (4), Gumba and Vlasenko (5), Harfst et al. (7), Kuznetsova et al. (10), Li et al. (11), Ramanathan et al. (22), and Yao et al. (26).

According to the third approach, innovations serve the interests of society, stimulating the increase of the level of social well-being and sustainable development. Attention is also paid to possible negative consequences of innovations: unemployment and climate change. The global, national, and regional aspects of innovations are considered. This approach is used in Ragulina et al. (21), Ragulina (20), and Zavyalova et al. (27).

According to the fourth approach, innovations are a source of competitiveness at all levels—from micro-economic to global. In the conditions of the Fourth industrial revolution, innovations are concentrated mainly in the hi-tech sphere. That's why they are often identified with digitization, and, apart from classical competitiveness, digital competitiveness is evaluated as well. This approach is seen in Popkova (12), Popkova and Sergi (13), Popkova and Gulzat (14), Popkova and iGulzat (15), Popkova and Parakhina (16), Popkova and Sergi (18), and Popkova and Sergi (19).

Despite the large number of publications, the context for which the above aspects are peculiar and the conditions at which the consequences of innovations are more or less expressed are not specified by economics. This is a gap in the system of the existing knowledge and a barrier on the path of formation of a paradigm modern treatment of innovations.

Correlation analysis is used for determining the consequences of innovations in all studied aspects and for determining the differences between developed countries (by the example of the OECD countries with the highest values of Global Innovation Index) and developing countries (by the example of BRICS countries as the most progressive countries) in 2020 (Table 1 (for all indicators' values—the higher the better).

According to the existing approaches, we offer the following research hypotheses:

- Hypothesis H_1: there's close direct connection (higher—above 50%—positive correlation) between attitudes towards entrepreneurial risk (11.05. Attitudes towards entrepreneurial risk, d) and companies' implementing breakthrough ideas (11.08. Companies embracing disruptive ideas, e), calculated within the Global Competitiveness Index 4.0 by the World Economic Forum;
- Hypothesis H_2: there's close direct connection (higher—above 50%—positive correlation) between the Global Innovation Index (a), calculated by Cornell, INSEAD, WIPO, and the rate of economic growth (b), calculated by the International Monetary Fund;

Table 1 Statistics of innovations and their hypothetical consequences in countries with difference financial positions in 2020

Category of countries	Country (by decrease of the global innovation index)	Global innovation index, points 1–100	Rate of economic growth, %	Quality of life index, points 1–200	Attitude towards entrepreneurial risk, points 1–100	Companies' implementing breakthrough ideas, points 1–100	Digital competitiveness index, points 1–100	The global competitiveness index 4.0, points 1–100
		a	b	c	d	e	f	g
Top 5 OECD countries by the global innovation index (favorable financial position)	Switzerland	67.24	1.600	196.08	59.1	53.8	94.648	82.3
	Sweden	63.65	2.181	180.52	67.5	59.6	96.07	81.2
	USA	61.73	2.121	176.77	75.9	68.1	100	83.7
	Netherlands	61.44	1.732	186.41	65.9	62.3	94.261	82.4
	UK	61.30	1.606	166.73	65.3	59.3	88.691	81.2
Countries of BRICS (unfavorable financial position)	Brazil	33.82	1.954	103.87	51.1	46.8	57.346	60.9
	South Africa	34.04	2.198	135.75	54.5	50.8	60.865	62.4
	India	36.58	7.791	115.41	55.2	51.7	64.952	61.4
	Russia	37.62	1.500	104.05	52.7	44.0	70.406	66.7
	China	54.82	6.000	99.87	58.4	53.8	84.292	73.9

Source Compiled by the authors based on IMD (8), Institute of Scientific Communications (9), World Bank (25)

– Hypothesis H_3: there's close direct connection (higher—above 50%—positive correlation) between the Global Innovation Index (a), calculated by Cornell, INSEAD, WIPO, and Quality of Life Index (c) Numbeo;
– Hypothesis H_4: there's close direct connection (higher—above 50%—positive correlation) between the Global Innovation Index (a), calculated by Cornell, INSEAD, WIPO, and the Global Competitiveness Index 4.0 (f) by the World Economic Forum, and the Digital Competitiveness Index (g) by IMD.

For all offered hypotheses, the differences in correlation between countries with favorable and unfavorable financial positions should be minimal (below 10%).

3 Results

The results of verification of the offered hypotheses are shown in Figs. 1, 2, 3 and 4.

As shown in Fig. 1, the connection between the indicators is strong and direct in both categories of countries. In developed countries, correlation of attitudes towards

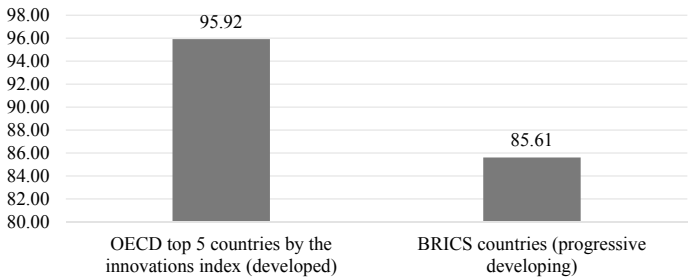

Fig. 1 Correlation of attitude towards entrepreneurial risk and companies embracing disruptive ideas, %. *Source* Developed and compiled by the authors

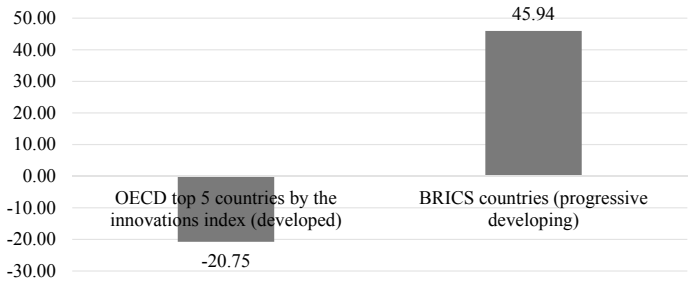

Fig. 2 Correlation of the global innovation index with rate of economic growth, %. *Source* Developed and compiled by the authors

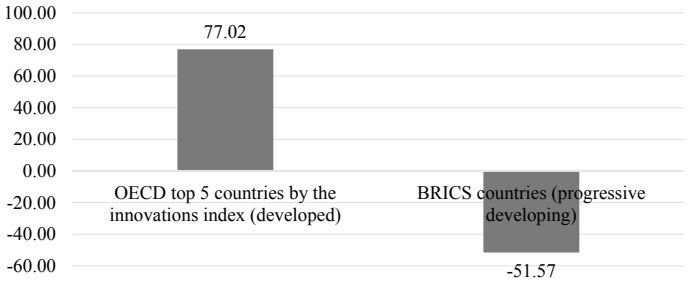

Fig. 3 Correlation of the Global Innovation Index with the Quality of Life Index, %. *Source* Developed and compiled by the authors

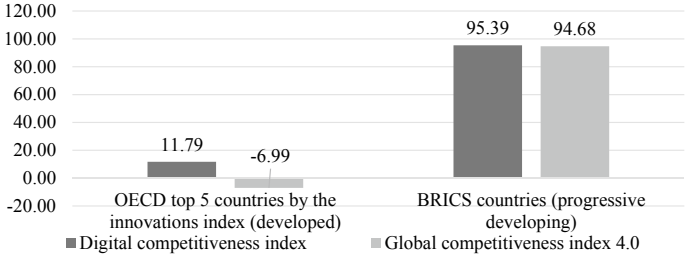

Fig. 4 Correlation of the global innovation index with the global competitiveness index 4.0 and the digital competitiveness index, %. *Source* Developed and compiled by the authors

entrepreneurial risk and Companies embracing disruptive ideas constitutes 95.92%, and in developing countries—85.61%, which proves hypothesis H_1.

As shown in Fig. 2, correlation of the Global Innovation Index with rate of economic growth is positive only in developing countries, but it is small (45.94%), and it is negative in developed countries (-20.75%)—which disproves hypothesis H_2.

As shown in Fig. 3, correlation of the Global Innovation Index and the Quality of Life Index in developed countries is positive and high (77.02%), and in developing countries it is negative (−51.57%). This proves hypothesis H_3, but imposes a limitation (condition)—it is correct only for developed countries.

As shown in Fig. 4, correlation of the Global Innovation Index with the Global Competitiveness Index 4.0 developing countries constitutes 95.39%, and with the Digital Competitiveness Index—94.68% (it is high and positive in both cases). In developed countries, correlation of the Global Innovation Index with the Global Competitiveness Index 4.0 constitutes 11.79% (very small), and with the Digital Competitiveness Index −6.99% (negative). This proves hypothesis H_4, but imposes a limitation (condition)—it is correct only for developing countries.

4 Conclusion

The results of the research have shown that the existing approaches to study of innovations are correct and reflect different aspects of innovations, all of which are effective. However, there are substantial differences between developed and developing countries, which show that the consequences of innovations are largely determined by the financial position of the country in which they are performed. The quality of innovations that is connected to their ability to be a mechanism of crisis management has not been found in developed or developing countries, and thus it cannot be considered a universal characteristic of innovations and should not be included into their basic definition (it is a private case, observed in a strict context).

As a result of the research, a paradigm modern treatment of innovations is offered - as a flexible mechanism of socio-economic development, connected to high level of risk and depending on the economic subjects' readiness to accept the risk, able to raise quality of life in case of its high level (shown by the example of developed countries) and to increase global competitiveness and digital competitiveness in case of its low level (shown by the example of developing countries).

Digital Economy and Financial Marketing: Mutual Influence and Ways of Development

Oksana M. Mahalina, Viktor N. Mahalin, and Yuriy Yu. Zaets

Abstract Development of the digital economy and usage of new IT and the necessity for collection, processing, storing, and exchange of Big Data led to transformation of corporate marketing in the changed conditions of the external and internal environment. The main trends of development of marketing according to the technological modes are shown; Marketing 3.0 of the Fifth mode is analyzed; the necessity for developing and implementing digital marketing is substantiated, and its advantages as compared to traditional marketing are considered. Transformation of marketing in the digital economy does not influence the scientific and practical foundations of marketing. The directions (tasks) of marketing activities, which cover the whole life cycle of a product from development to consumption, remain unchanged. Digital marketing uses the terms, methodology, concepts, and principles of management of traditional marketing. Also, transformation of new types of activities takes place in traditional marketing: e-commerce, online advertising, etc.; conditions for simultaneous usage of information resources of the digital economy and the objects of marketing activities with the opportunities for their modernization in the process of usage and exchange are created. Usage of digital IT in marketing allows improving the assortment policy and increasing the sales volumes. The main directions of development of financial digital marketing in Russia are formulated: increase of the number and improvement of quality of specialists training in the sphere of marketing activities, development of strategies of diversification; mastering of production of new goods, services, and markets; development and improvement of marketing technologies; increase of technical equipment of marketing services; improvement of marketing activities.

1 Introduction

An important stage of the global development of recent years is emergence of new and transformation of the existing types of professional activities that are based on collection and usage of data in the digital form, application of digital technologies, as a result of which new economic interrelations are built, and a new economy is formed—the digital economy, which is based on usage of information and communication technologies. In the process of development of the digital economy, a lot of organizations face the necessity to collect, process, accumulate, and analyze and disseminate marketing data, which volume has a tendency for constant growth. A new information infrastructure of the market is formed—it contains personalized information on each potential consumer, which could be used for the marketing purposes. Using this accumulated information for satisfying the individual target needs of market representatives is possible under the condition of usage the leading IT in marketing. In the conditions of functioning of the digital economy and dissemination of IT, the transformation of the conceptual foundations of marketing activities takes place.

2 Methodology

The problems of development of marketing and usage of digital technologies in marketing, as well as the modern trends of informatization of financial marketing, were studied by Philip Kotler, Gary Armstrong, Y. N. Solovyeva, O. U. Yuldasheva, T. B. Nadtoka, I. V. Rozhkov, G. A. Kornilov, etc. However, the works on transformation of the complex of marketing activities into the digital economy are not enough. Thus, the purpose of this paper is to study the problems and to develop a complex of recommendations on formation of digital corporate marketing depending on the level of the digital economy development. The authors use the concept of the marketing approach, according to which company's achieving the set goals fully depends on the needs and eventually on effectiveness of satisfaction of the target consumers' needs.

Using the statistical, economic, and organizational analysis, the most perspective directions of IT application in marketing activities are substantiated, and the main trends of development of marketing, which is based on usage of the concepts of Big Data and marketing 3.0, are determined; the necessity for implementing the principle of customer-oriented approach in the market of marketing services and

applying customization based on modern IT. Strategic analysis of marketing activities of companies and organizations and its results are a necessary basis for developing the forecasts of improving the strategies of interaction with the marketing activities' participants in the near future and developing the recommendations for the programs of training (retraining) of marketing specialists. Inclusion of the practice-oriented disciplines, which are directly connected to application of IT in the marketing activities in the conditions of the digital economy functioning, is substantiated.

3 Results

Despite the fact that the notion of the digital economy appeared in the foreign economic literature in 1994, this term is widely used by economists, politicians, entrepreneurs, and journalists. There appeared a sphere of economy in which the specific subject of production activities interact, special platforms and technologies form, the participants' competencies are developed and improved, and an environment, which ensues the interaction of participants of markets and spheres of economy, normative and legal regulation, information infrastructure, personnel provision, and information security, is created. Thus, a new economy appeared—it uses online means of processing, storing, and transfer of data, based on the digital computer technologies [1].

The digital economy reduced the costs of search, processing, exchange, and storing of information and raised the role of obtained information, as a resource of companies and people in management systems. All this influenced the marketing activities of companies. The volume of processing, accumulation, analysis, and dissemination of marketing data grows exponentially; the data contain personalized information on each market participant, which could be used in the process of marketing. The volumes of information grow by two times very two years and this process becomes quicker. According to early forecasts of IDS, it should have increased by 44 times in 2020, as compared to 2009; the forecast constantly changed and now we have the indicator of 55 times. The main generation of data will be performed not by individual users but industrial companies. Therefore, it becomes more difficult for managers and marketing specialists to process such array of information and make effective managerial decisions on its basis [2].

Marketing specialists should have the research and analytical competencies on determining the potential opportunities and threats to company's external environment and be ready to evaluate its pros and cons as compared to the whole financial market and its separate segments, connected to consumers, rivals, and other economic subjects [3]. IT are widely used in marketing activities—so one of the types of threats for companies is IT crimes. According to the Ministry of Internal Affairs of the Russian Federation, 300,000 cybercrimes were conducted in 2019. This indicator showed enormous dynamics—the number of cybercrimes in 2018 was by 68.5% smaller. According to the MIA's statistics, IT-related crimes account for 14.4% in the total number of crimes, while in 2018 this indicator constituted 8.8%. Almost

half of all cybercrimes (48.5%) belong to the category of serious and very serious crimes. Thus, their number in 2019 was 142,700, which is by 149% more than in 2018.

These problems could be solved only on the basis of wide usage of software with elements of AI in marketing and simultaneous transformation of the conceptual foundations of the marketing activities. Let us consider this process in development, according to the technological modes, which are a totality of technologies and technological operations that are characteristics of a certain level of production development. Six technological modes are distinguished in Russia, with the last one still in development. The times periods of these technological modes are as follows: 1st—1785–1845; 2nd—1845–1900; 3rd—1900–1950; 4th—1950–1990; 5th—1990—until now [4].

According to the existing classification of the stages of development of marketing, offered by P. Kotler, "Marketing 1.0" belongs to the Third technological mode. In this period, marketing should have provided the maximum number of consumers with competitive products. The products' competitiveness was ensured by means of unifying the products and optimizing the costs for their production based on the leading technologies. Therefore, it is possible to state that at the first stage of development of marketing the main role belonged to manufactured products [5].

The Fourth technological mode corresponds to the next stage in development of marketing—"Marketing 2.0". It was influenced by the level of development of the post-industrial society, based on IT. At the same time, consumers' requirements to their information provision during selection of a variant of purchased products grew. In order to solve this task, marketing had to be reequipped technically and to implement and use new technologies of collection, processing, storing, and transfer of information.

The Fifth technological mode is peculiar for usage of modern IT, which fully changed the communication system of consumers and business and ensured usage of PC's and telecommunications in all spheres. This technological mode corresponds to the modern marketing ("Marketing 3.0"), which considers consumers to be "… human beings with emotions and souls" [6, 7]. There's a demand for satisfaction of not only functional but also emotional needs, which belong to the upper part of the Maslow pyramid and which appeal to the necessity for self-expression and self-realization of human in society [8]. The means for satisfying such demands are provided by the modern IT: social networks, mobile devices, unlimited Internet access, and platforms of collective interaction of people based on information services—fundraising and crowdsourcing [9]. In this paper, we analyze transformation of marketing depending on technological modes. That's why we shall not study the influence of the digital economy on the marketing activities in the aspect of a complex of marketing (4P, 7P, 4C).

The Fifth technological mode is peculiar for development of IT, micro-electronics, Internet, genetic engineering, and software and growth of individual production and consumption, speed of communications, and movement. The achievements of this mode include development of the global industrial systems, transition to renewable energy sources, creation of the industry of composite materials, 3D printers,

unmanned vehicles, and development of biotechnologies and AI. In the Fifth technological mode, the Fourth industrial revolution (Industry 4.0) envisages usage of industrial production, controlled by AI, which uses data exchange with external environment and the possibilities of the digital economy (Internet of Things and cloud services).

Implementation of Industry 4.0 should raise the level of production organization and management of value creation chain [10]. This means that there should appear distributed production and energy, free access to their services; intermediaries will disappear, and direct contact between manufacturer and consumer will be established. This will require transformation of marketing and its adaptation to the requirements of the modern digital economy, which envisages wide application of digital technologies, Big Data analysis, and usage of other achievements of modern technologies for influencing the formation of each customer's needs. Thus, marketing activities will be conducted with the usage of information and communication technologies and systems. This process is called digital marketing.

It covers three main directions of product promotion: social media marketing, search marketing, and email—marketing [11].

Why is it important to implement digital marketing? What advantages does it have as compared to traditional marketing? These and other questions are asked by entrepreneurs of various levels of management. Let us try to give short answers.

1. Using complex strategies of digital marketing, new tactics, the innovative approach to customer, based on deeper understanding of users in digital marketing allows reaching success in any business.
2. Digital marketing envisages operative interaction with potential customers, and this means the possibility to contact the customer in the required time and place and with the correct offer.
3. Digital marketing leads to increase of sales volume and growth of traffic; it includes the mandatory feedback with the customer. It allows for quick increase of the number of customers in the target audience, increase of interest to the offered product or service, increase of the effectiveness of new product's promotion, or stimulation of sales' growth.
4. Unlike traditional marketing, its digital version allows using several channels at the same time for building communication ties with potential customers. The main channels of building direct ties with the target audience are as follows: Internet marketing, search optimization, PPC—advertising (pay per click), content marketing, email marketing, promotion of social networks, and videomarketing [12].
5. Digital marketing allows tracking the process of implementation, promotion, and selling of product and reduces consumer cost of a product by means of reduction of overhead costs, execution of certain functions by consumers, individualization of offer, and adaptation of the product's characteristics to specific needs of a buyer.
6. In case of application of digital marketing, its target audience cannot be a passive consumer—it is necessary to ensures its active participation, as a co-performer in promotion, dissemination, and creation of the necessary product.

7. Digital marketing, unlike Internet marketing, envisages not just increase of the number of attracted customers but usage of digital technologies for keeping them. Internet is used as the main channel of delivery of information (radio, TV, advertising digital screens, mobile apps, QR codes, etc.)

Transformation marketing in the digital economy does not influence the scientific and practical foundations of traditional marketing. Thus, the directions (tasks) of marketing activities that cover the whole life cycle of a product, from development to realization, remain unchanged [10]:

– studying the needs and demand of buyers;
– studying the possibilities of using a certain trademark or packaging in a certain market;
– developing and implementing measures that are aimed at satisfaction of the determined needs;
– establishing the acceptable—for the company and consumers—prices in view of the market type (regional, national, external) and the category of buyers;
– informing consumers on specific features of new goods or improved old goods;
– persuading consumers that the offered products are of high quality and offering them the required list of services in the after-sale period;
– keeping constant communication with consumers for timely determination of the desired improvements or development of the desired products.

The main quality of transformation is shift of the main sales' focus from wide and stable demand for goods and services (mass market), which is often characterized by low prices, and reorientation at the segment of unstable demand, which is ensured by certain groups of consumers or individual consumption, which envisages higher price. Individual demand envisages increase of price, but, for the purpose of long-term interest of customer, makes the supplier offer a wider set of services, which accompany sales and after-sale features. This is vividly manifested in the sphere of digital financial marketing, which is aimed at effective management of implementation of various financial assets or financial tools and attraction of potential buyers for purchasing and further managing the formed financial assets.

Besides, digital marketing continues to use the terms, methodology, concepts, and principles of the traditional marketing management. Classification of the types of marketing, depending on the character of demand, is preserved:

– Conversion—envisages the changes of skeptical attitude of the consumers to a product;
– Stimulating—aimed at attraction of interest of the consumers who were indifferent earlier;
– Fixed—characterizing stable demand for specific types of products (financial assets);
– alternative—demand based on rational choice;
– developing—aiming at determining potential demand;
– impulsive—unexpected change of demand, under the influence of advice, advertising, or other factors;

– remarketing—aiming at supporting the existing production or structure of demand;
– supporting—aiming at supporting the existing structure of demand;
– demarketing—aimed at reduction of demand in case of the lack of production capacities;
– opposing—aiming at liquidation of irrational demand, etc.

4 Conclusions

The following generalized conclusions on the influence of the digital economy on company's marketing activities were made:

– transformation in traditional marketing of new types of activities: e-commerce, online advertising, etc.;
– reduction of overhead costs by means of cheap process of communication and informatization of commercial product and absence of online stores' need for storages and show rooms;
– differentiating prices for similar products by means of better informing of consumers regarding the cost and indicators of quality and the level of service at domestic and world markets;
– simultaneous usage of information resources by the digital economy and objects of marketing activities with the possibility of their modernization in the process of usage and exchange;
– when using digital IT in marketing, it is possible to improve the assortment policy and increase sales volumes by means of using the specifics of products and channels of their distribution, which are influenced by the following factors: blogs, product reviews, forums and rankings, and change of the structure of advertising budgets in favor of Internet sales.

The modern level of development of digital marketing in Russia has to be raised for the following directions:

– improving the quality and quantity of training of specialists in the sphere of marketing activities. It is necessary to supplement the current professional standards—08.03.5 "Marketing specialist" [13]; "Internet marketing specialist" [10], etc.—supplemented by courses in the modern innovative technologies of information provision of digital marketing, for increasing the trend of informatization of marketing activities and competitiveness of young specialists in the labor market;
– developing the strategies of diversification, connected to creation of new productions and mastering of new markets (strategies of internationalization), and using the opportunities of the auxiliary character. For example, when producing and selling complex equipment, it is necessary to organize the systems of after-sale services (centers of service maintenance of users of complex equipment, centers for training of personnel, etc.) and create credit establishments within large companies for internal crediting;

– developing and improving universal and specialized marketing IT and increasing the level of technical equipment of the marketing services in view of its correspondence to the digital economy;
– improving the development and usage of the methodology of marketing of information systems, which ensure the procedures of collection, sorting, analysis, and evaluation of timely and correct marketing information, which is necessary for making marketing and managerial decisions;
– active usage of Big Data technologies, tools of marketing business analytics, neural network, modern tools of web analytics, methods of forecasting of sales of products and markets, and development of specialized programs for managing the marketing activities and forecasting;
– improving advertising activities by usage of the modern IT and all means of mass information, for quick dissemination of information on goods and services, acceleration of their sale, establishment of contacts between buyers and products, and stimulation of interest and desire to buy the product.

Using the Project Management Methods in Digital Marketing

Anton V. Zozulya, Natalya V. Titova, and Danijela Ciric

Abstract Modern companies often use digital marketing technologies for promoting their products. The purpose of this paper is to increase the competitive advantages of marketing companies by means of application of the system of project management in digital marketing. Development of the system of marketing services, including digital services, reached a stage when companies—within their budget—have to implement several separate projects, and companies' activities are largely based on services on implementation of separate projects. Thus, the problems of integration of projects into a common system of company management come to the foreground. Integration could be performed with the help of inclusion of the methods of project management in the system of company management. Within digital marketing, project management includes the following spheres of knowledge: managing project's contents, terms, quality, human resources, communications, risks, and supplies; integration of projects, which is connected to the marketing activities. Application of the system of project management during promotion of a product in the digital market leads to increase of company's competitiveness, increase of effectiveness of management, growth of efficiency of works on achievement of the project's goals, and attraction of new customers and investments. The global practice shows that implementing the system of management of marketing projects allows reducing project costs by 35% on average.

1 Introduction

At present, marketing technologies with application of digital channels are used in the global market for promoting products and communicating with audience. Like in classical marketing, the digital market has a range of tools that allow developing business, marketing, and communication tasks. Recently, investments in digital marketing have been growing steadily, being ahead of the average rates of growth of investments in other media resources. At present, more than 40% of all advertising expenditures account for various channels of digital communication. Not long ago, this indicator was much lower, barely reaching 30%. Such increase of the share of expenditures for digital marketing could be explained by significant increase of companies' expenditures for Internet marketing—one of the most expensive channels of digital marketing. Moreover, in the near future, the share of investments in digital marketing will start exceeding the share of other channels of interaction between advertisers and audience—i.e., it will be the leader from the point of view of distribution of budgets for marketing and media channels.

The most important reasons of digital marketing's popularity among companies are as follows [1–15]:

(1) "movement" of consumers towards digital channels;
(2) possibility of targeting;
(3) possibility to collect and process large arrays of information on consumers and make offers that are fully adapted to their preferences and needs.

Ratio of the volume of the global expenditures for advertising—in particular, digital advertising—in 2015–2020 is shown in Fig. 1.

Digital marketing is one of the services that is most often provided within advertising. According to the Association of Communication Agencies of Russia, the

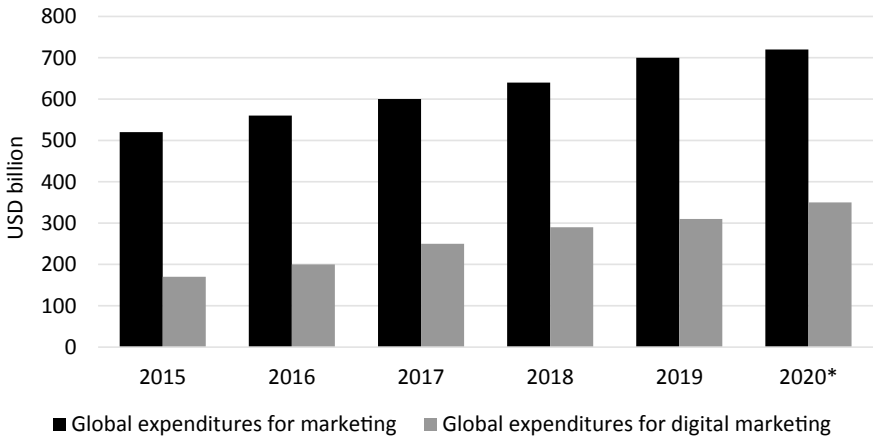

Fig. 1 Growth rates of global expenditures for marketing and digital marketing

advertising services market in Russia has been showing constant growth in recent years. The total volume of advertising constitutes RUB 460 billion in 2019, which was by 3% higher as compared to 2018. In 2018, Internet became the largest media platform of the advertising market in Russia from the point of view of expenditures—for the first time. As expected, Internet will be developing rapidly. The volume of the Internet advertising market shows constant growth: in 2019 it grew by 20% as compared to 2018, constituting RUB 225 billion; the second largest segment of the advertising market—TV advertising—showed negative dynamics of growth in 2019—7%, constituting RUB 160 billion. The total volume of the Russian market of marketing services reached RUB 830 billion, of which 40% accounts for digital marketing.

Digital marketing is a large part of the market, which includes a lot of various players, who interact with each other. In order to understand the market structure, competition in it, and the scheme of interaction between participants, it is necessary to generalize them in several main groups:

1. Advertisers (customers of agencies)—company of any sphere of activities and any scale, which is interested in promoting its services in the digital environment.
2. Advertising agencies—agencies of digital marketing, which provide services on implementing the projects on promotion of products or services, which are oriented at the users of digital devices. These agencies have certain professional competencies, know the specific features of media consumption of the digital audience, etc.
3. Research and audit companies. One of the specific features of digital marketing is its measurability. Placing an ad on Internet channels, it is possible to evaluate it based on a certain set of parameters, with the help of special systems of tracking and audit. Moving on Internet, a user leaves a lot of traces in the form of cookie files—which allow obtaining information and tracking the user's movement in the digital world.

The indicators that could be tracked when a user visits a digital platform include the following:

- Number of visits;
- Number of conversions (target actions);
- Time spent on a web-site;
- Depth of visit;
- Various groups of the audience (those who followed an ad, demographic, geographical, etc.).

Analyzing the above indicators, it is possible to see the person's interests, social status, location, and professional sphere of activities.

Thus, there is a large field for analyzing the effectiveness of digital marketing, making certain decisions based on it, and creating hypotheses. Measurability is what distinguishes it from other types of marketing.

Table 1 Registered users on the world's largest media platforms

Social network	Registered users (billion)
Facebook	2.4
YouTube	1.9
WhatsApp	1.6
Instagram	1.0
WeChat	1.0

4. Media sellers—agencies that sell advertising space. Their function is not limited by intermediary communications: they create certain offers and combine various marketing channels for an effective system of brand promotion.
5. Platforms. This subject of marketing and digital advertising consists of large platforms, which include a lot of web-sites and services. A lot of people visit these web-sites every day, due to which they have a large potential and are attractive for advertisers. The largest advertising platforms in the world are Google, Facebook, and others (Table 1). The largest Russian platforms are Yandex, Rambler, and Mail.Ru Group.
6. Systems of automatization and other services for managing digital marketing. Large volume of work in the market of digital marketing is provided by advertisers with a lot of projects in the sphere of promotion of products and services—which requires time and labor. This led to appearance of companies that provide additional services to participants of the digital market—e.g., automatizaton of the digital marketing projects. Companies note the large necessity for adapting the content of digital marketing to the modern automatization systems, which could cope with a lot of data and provide effective tools for interaction with a customer in the course of the project's whole life cycle.
7. Suppliers of data. Advertisers and other players of the marketing services market actively work with the data of social media platforms' users and exchange these data. Experts say that the volume of the users' data market will increase in the short-term, for data suppliers have access to a large array of information—including personal information.

In view of development of marketing and communications and based on the accumulated information on users, participants of the digital marketing market will be strengthening their positions and increasing the field of their activities. Large important of data in the modern world led to an expression "Data is new oil". In 1815, Nathan Rothschild said, "He who owns the information, owns the world".

2 Methodology

Development of the system of marketing services, including digital services, reached a stage when companies—within their budget—have to implement several separate

projects, and companies' activities are largely based on services on implementation of separate projects. Thus, the problems of integration of projects into a common system of company management come to the foreground. Integration could be performed with the help of inclusion of the methods of project management in the system of company management.

Flexible methods of project management have become very popular. Their main difference from the traditional methods is that emphasis is made not on the formal procedures, rules, and tools of project management but on interactions and communications between people who are involved in the project. Supporters of the flexible methods in project management think that a working product—i.e., value for consumer—is more important than documents and reports on the project. The next aspect emphasizes the large importance of interaction with the customer—this is considered to be more significant than contractual obligations. As it is impossible to envisage and include everything in a contact, human interrelations come to the foreground. Also, the new direction changes the attitude to constantly emerging changes in the project. In the traditional project management, changes in an approved project were undesirable. The modern tendencies consider changes as a rather wise development of a project. Changes are welcome in the course of development and implementation of the project—if they allow creating additional value for the customer. It is possible to state that flexible methods of project management move to the foreground human interrelations and creation of real value for the customer.

All these tendencies fir the project that are realized within digital marketing. This market has a lot of participants and interested parties and is peculiar for large diversity of customer requirements. In order to meet up these requirements, companies that provide marketing services have to react to the changes. This is possible if companies use flexible methods of management for the project.

All main directions of the projects of digital marketing could be grouped according to the functions of digital marketing:

- research of the market within digital marketing;
- works within target marketing;
- managing a product or service in the digital space;
- managing product's price during promotion in the digital space;
- managing product's promotion in the digital space;
- managing distribution;
- managing digital marketing.

Within digital marketing, project management includes the following spheres of knowledge: managing project's contents, terms, quality, human resources, communications, risks, and supplies; integration of projects, which is connected to the marketing activities.

Activities of a marketing company are a complex of large and small projects at different stages of the life cycle. That's why it is important to have skilled marketing specialists with knowledge in the sphere of project management. Application of knowledge of project management in digital marketing allows controlling all processes and projects, reacting to the emerging problems, improving the operative

and strategic plans, and working according to the plan even in case of a deadline. Possession of knowledge in the sphere of project management develops a marketing specialist's systemic vision of tasks and processes—which is especially important during development and implementation of marketing strategies.

Practice shows that project management is applied widely in economy on the whole and in the marketing activities in particular. The system of management of marketing projects allows preserving the adopted plan, minimizing the risks of deviation, optimizing the processes of interaction between departments, and accelerating the coordination of the necessary works within the project, thus reducing non-production expenditures. It is necessary to understand that the digital economy on the whole and digital marketing in particular are based on technologies. At present, development of technologies and digital directions is one of the most perspective and important directions in the world, with a lot of investments from large and small companies.

In most cases, the structure of the system of project management of a marketing project does not coincide with the company's organizational structure of management. Usually, companies' employees form departments according to their functional responsibilities. In order to work on a project, it is necessary to form teams, which consist of full-time employees of various structural departments of the organization—which simplifies the interaction between the departments and accelerates the process of coordination of works—and other specialists in the sphere of project management, marketing, IT technologies, etc.

The practice of project management shows a shift of emphasis from formal methods and procedures to more creative approaches. This is true for the organizational structures of management in organizations. The structures that are involved in a project have large organizational flexibility, without complex hierarchies, procedures of decision making, and introduction of changes. Project teams have large freedom of creative search, with stimulation of positive attitude to risk. Team members are at the same hierarchical level, and structures are horizontal, not vertical—which stimulates the large interest in a project, aimed at achievement of the result.

3 Results

It is possible to state that the traditional form of management in the sphere of digital technologies, including marketing, complicates the work on a project and often makes its realization impossible, due to complexities of obtaining information, large time required for coordinating the works on a project at each stage of the life cycle, and absence of experience of realization of similar projects and ready technologies.

Application of the project system of management—especially flexible technologies—in digital marketing provides significant advantages, as compared to implementing projects in the conditions of a traditional system of management. The advantages of the system of project management in digital marketing are as follows:

1. Increase of effectiveness of the realized project solutions by means of quick reaction to the change of customer's requirements.
2. Creation of additional value for consumer in the course of execution of the project.
3. Formation of creative teams, aimed at achievement of the unique result for a specific consumer.
4. Reduction of time required for achieving the goal of the projects.
5. Reduction of the expenditure part of the budget and increase of effectiveness of the system of management as a result of clear coordination of the flows of project resources and actions of the performers.
6. Reduction of the probability of errors during achievement of the project goals as a result of putting the customer's representatives in the project team.
7. Strict control over execution of the project budget.
8. Formation of project teams allows implementing several large projects at the same time within one marketing company.
9. Personal responsibility of the project team members for execution of the control indicators of the marketing plan.

Application of the project management system allows companies that work in the market of digital marketing the following:

– increasing the effectiveness of communications between various functional departments and between performers and consumer;
– ensuring compliance with all desires of the advertisers and the possibility of changing and improving the plans in the process of execution of the marketing project;
– preparing a competitive product at the digital platform;
– increasing effectiveness of works on promotion of a product at the digital platform.

Application of the project management system during promotion of a product in the digital market stimulates the increase of company's competitiveness, increase of the effectiveness of management and efficiency of works on achievement of the project goals, and attraction of new customers and investments.

The global practice shows that implementing the system of marketing projects management allows reducing project costs by 35% on average.

4 Conclusions

The necessity for formation of the system of marketing projects management in the activities of digital marketing is predetermined by several reasons. Digital marketing is a relatively new and specific sphere, which requires quick reaction to the changes of planned indicators, customer's expectations, and pricing and innovative policy of rivals and main partners. In order to increase quality and effectiveness of usage of resources and observation of the plans of project implementation, it is necessary to ensure high quality of management within the project and organization on the whole.

Preparation and implementation of projects in the sphere of digital marketing require managers of all levels of the system of organization management, with competencies in marketing, project management, and risk assessment.

The Russian system of education has higher educational establishments that prepare skilled managers. A special place belongs to State University of Management—the first managerial university with a history of more than 100 years, which has been training specialists of various levels in the sphere of project management and marketing for more than twenty years.

Acknowledgements The authors would like to express their gratitude to the management of State University of Management, Rector Ivan V. Lobanov, and Director of the Institute of Sectoral Management of State University of Management V. I. Tinyakova for the support during preparation of the paper.

Smart Department: Designing Digital Applications for Smart Organizations

Irina Z. Kogotkova, Gregory Ya. Soroko, and Mariya N. Guseva

Abstract The changes in the intellectualization of information processes of business and organizations that have occurred in recent years require the adequate transformation of modern educational environment. Information processes in educational organizations have a number of features, which have a significant impact on their automation. This is primarily due to the fact that in them the main "production" process—the learning process, is an information process that is intimately intertwined with the information management processes of the organization. The article analyzes the existing digitalization experience of educational and managerial processes, and the possibility of their integration. The analysis revealed the lack of interconnection between the parameters of the existing university management automation systems and the department-level information processes, which in recent years have endured very significant changes in the direction of complicating and increasing the volume of information. Meanwhile, the educational process and educational process management are integrated at the cathedral level. The university departments rightly classify the number of so-called intellectual organizations, the effective activity of which in modern conditions should be based on the maximum possible using of the capabilities of modern digital technologies. Based on the analysis, a new methodological approach to the formation of a fully functional digitalization system of the chair activity of Russian universities was developed and presented. This approach is considered in the context of the concept of a "smart department", which is proposed by the authors, that is, a department, whose activities are supported by an integrated automation system for all information processes at the department level. Consideration is given to the concept of "smart department" on the basis of creation of digital applications, which cover all areas of its information activity. The authors

have described the conceptual model of a "smart department", that is, a department whose activities are supported by the totality of modern digital applications.

Keywords Digitization · Smart organization · Digital technologies · Educational technologies · "smart department"

JEL Classification A22 · I23 · M15

1 Introduction

SMART technologies determine the modern strategy of development of the information society. Their use is intended to improve all aspects of the socio-economic existence of a man. Main trends of digital transformation: development and introduction of cross-cutting digital technologies; digital platform distribution; a growing imbalance of opportunities and needs in the labor market; heavy need of society for lifelong education and improvement of digital literacy—are the main challenges for the educational environment of Russian higher education [1].

SMART society and SMART business present universities with a global task—making it possible to acquire professional competencies through education that is relevant to modern requirements. The content of the concept of SMART universities and departments is interpreted differently in each country. But the main emphases are on the flexibility of learning in an interactive educational environment, personalization and adaptation of learning; free access to content around the world [2].

2 Background and Methodology

The main purpose of the research, which is presented in the article, is developing a methodological approach to the design and implementation of modern SMART technologies, focused on the integrated automation of information activities of managers, teachers and employees of departments of Russian universities.

The methods of system analysis, modelling, comparison, and abstraction were used in the research.

The scientific novelty of the study is the fact that, based on an analysis of information processes at the department level and the existing technologies for their automation, a methodological approach to the formation of a fully-functional digitalization system for the department's activities for the integration of the educational process and educational process management processes at Russian universities has been proposed for the first time.

In the process of the study, an analysis of the content and structure of information processes at the department level, an analysis of practical implementation experience,

methodological approaches and trends in the development of digital technologies in order to improve various areas of activity of Russian universities were made.

On the basis of experimental research and the introduction of a number of applications in order to test the developed concept, a functional structure of the conceptual model of the digital department (SmartDepartment) has been developed, which allows outlining the range of basic computer applications necessary for its effective operation.

The concept of smart organization has emerged and has been widely used in recent years [3]. The main distinguishing feature of such organizations is their ability to generate new knowledge. The emergence of organizations mainly related to intellectual activity is stipulated by the trends of development of the information society.

Today, the volume of knowledge processed by smart organizations has reached a level where their performance critically depends on digital technologies of information processing they use.

This fully pertains to university departments that are a perfect example of smart organizations [4].

Effective operation of a modern department is impossible without the support of advanced digital applications. However, the main focus today is on the automation of activity of administrative units, e-learning and SMART–campus. And the tasks solved at the departments are touched upon to a minimum extent. To solve an ever-expanding range of tasks, department employees have to use a variety of unrelated applications [5].

At the same time, changes in education that have occurred in recent years cardinally changed the content of information processes at the departmental level [6]. In order to ensure their efficient implementation, it is necessary to create digital applications that would establish control over all information activities of the department.

The design and introduction of a set of such applications will make it possible to use the concept of "smart department" in its contemporary fullest interpretation.

Development and implementation of digital applications for the "smart department" of a university requires using a system-wide approach [7–14].

The development of the process conceptual model of a "smart department" is an essential prerequisite for creation of digital applications to ensure its functionality.

The development of the conceptual model under consideration is also based on a descriptive (descriptive) methodology for building automation systems, the main principle of which is an orientation towards an individual approach to the formation of the functionality of each element of the model, depending on the needs of end users.

Digital applications of an organization are organizational management systems. Their functional subsystems require constant and continuous changes and development. This is due to constant changes, both in the organization as such and in the environment in which it has to function. Legislation is changing, novel technologies emerge, new requirements of decision-making structures arise, etc.

In this regard, the choice of computer technologies, which is used to implement the developed conceptual model, is extremely important. Its capabilities to a large extent determine the effectiveness of its practical implementation. The stack of digital technologies used should provide quick adaptation of the system to changes, both in the content of organizational processes and in the development of development technologies themselves.

3 Discussion and Results

In accordance the research conducted by the authors (2017–2019), we have identified the functional structure of the automated system which will make it possible to provide information support for the learning activity of university departments to the fullest extent possible.

The use of such a system which has been designed and implemented taking into account the capabilities of modern digital technologies, will allow to hold out the department using it as a "smart department". The conceptual model of a "smart department" may be represented by a number of digital applications. Digital applications (subsystems) of the integrated automated system referred to as "smart department" must include the following:

1. Computer knowledge base (CKB) of the department.

The concept of the departmental CKB can be used to express various meanings.

In a broad sense, such a basis can be understood as the entire integrated information system of the department, since all its subsystems are associated with information that facilitates departmental activities.

The concept of the departmental CKB is used in a more narrow sense here. This is a computer database which contains knowledge of the subject-matter area in which the department is specialized.

Computer-based knowledge base can be considered as the model of the subject-matter area that will be formed from all traditional sources of knowledge. It is expedient to take the content of special disciplines taught at the department as the basis for the formation of its structure. The set of these disciplines should form professional competencies of a student; therefore, these disciplines should cover the entire set of issues related to the training of a corresponding professional.

It is expedient to conveniently divide the computational model of the subject-matter area into three levels.

The first level should include its thesaurus – that is, a dictionary of concepts of the subject-matter area (glossary) and the relations between them, as well as knowledge of the subject-matter area, structured in the form of computer-based encyclopedic dictionary and (or) encyclopedia.

It is the core of the knowledge base, which is a computer-generated hypertext, linking all its elements into a single whole.

Content elements of encyclopedias are referred to as articles. It seems correct to use this term to refer to elementary (further indivisible) objects of the knowledge base.

Topical review questions, presented in the work programs of special disciplines, should be regarded as the items of the departmental CKB.

Experts may have different, sometimes diametrically opposing opinions on the same issue. If this is the case, it is expedient to present all points of view in the departmental CKB supplying them with complete argumentation.

In the departmental CKB, it will be possible to post articles of various sizes on each issue by analogy with how articles are differentiated in encyclopedic dictionaries, encyclopedias and large encyclopedias.

The second level is the information environment of the core of the knowledge base, which is formed by computational models of all informational traditional sources of knowledge that are placed in it: books, articles, periodicals, scientific reports, reports on specific projects, etc.

The third level is the level of the so-called meta-information about sources, which will provide access to them in the information space which is external to the department. The information space of any subject-matter area is infinite. There will always be sources that are not presented in the computational model of the departmental database.

The offered approach to the formation of the core of the departmental knowledge base will provide flexible interaction with other digital applications of the integrated system for the automation of departmental activity.

2. Computational models of work programs of disciplines (WPD).

The computational model of work programs of disciplines (WPD) should be understood as a digital application which ensures processes of their creation, arrangement and usage.

If we focus on the above-offered approach to the formation of the core of the departmental knowledge base, then the content-related portion of WPD can be considered as a certain sample from the knowledge base, prepared by the teacher based on his ideas about the logic of the cognitive process. As a matter of fact, the teacher designs a model of the cognitive process, shaping its path and time parameters. Since WPD at the department have already been developed, formation of the computational model of WPD should be combined with the formation of the core of CKB.

In proportion to the development of the subject area, there will be a need for writing new articles for the CKB. This knowledge should also be included in topical review questions of departmental disciplines.

Development of the computational model of WPD is important in itself, without correlating it with the departmental CKB. However, the combination of these subsystems conceals a powerful reserve of intellectual capacity of the department.

3. Digital learning support system

The learning support system should be directly related to the computational model of WPD, since the object of study is a specific discipline, its sections, topics and topical review questions. The topical review question is an elementary unit of the departmental CKB and content-related portion of WPD. The topical review question is a direct object of cognition.

The computational model of WPD should provide access to the informative content of the discipline and each of its components.

It must be emphasized that the digital learning support system is not designed and suitable for the independent study of the discipline without the involvement of a teacher.

Today, smart education is generally understood to mean distance learning [15]. However, the leading top-rated universities use these technologies solely to complement traditional approaches.

The computer support system for the education process should complement the computational model of WPD, which presents all methodological aspects of mastering the discipline, and the support system provides the students with the information content on the subject and allows for self-assessment of knowledge gained.

4. Educational process planning system at the level of departments

The most important document for the organization of the educational process is the curriculum of the education program. It is prepared by the educational departments of higher educational establishments through the use of automated systems at the university level. Such systems provide departments with access to view and print out curricula.

The functionality of such systems for the departmental level is actually restricted to this.

But since the curriculums are the basis for the implementation of the education program, they are needed for solving a wide variety of tasks at the departmental level. They determine the composition of special disciplines for which WPDs are formed, planning and accounting of academic workload at the departmental level, scheduling of departmental activities in general, since several curricula are simultaneously implemented at the department, etc.

The existing automated systems at the university level are largely focused on supporting the activities of administrative units and are poorly adapted to solving the tasks at the departmental level. Similar remarks can be made for a set of tasks of planning and accounting of academic workload, timetables etc.

In this regard, it is necessary to have a scheduling system at the departmental level, which would integrate all areas of its activities and ensure smooth systematic work.

5. Document management at the department

The existing workflow systems in higher educational establishments are also classified as the systems at the university level. The departments have interfaces for entering certain documents: administrative notes, group orders, etc.

The introduction of the workflow system makes it possible to significantly reduce the amount of time required for solving many operational issues. However, some functionality is accessible to the department in strict time intervals, and does not provide the proper quality of preparation of documents, thus they require numerous amendments in the future.

A great variety of documents circulate in the department, which are not pertaining to the university workflow system and are made through the use of standard office programs. That said, the size of File Register at the Department has almost doubled over the past few years, and the number of planning and reporting documents has dramatically increased. In this regard, when the conceptual model of an integrated system of digital applications at the departmental level is formed, one should include a workflow system in it.

6. Regulatory management system of the department

At present, the level of complexity of information processes has become so high that it necessitates a system that would contain the model of the regulated functional processes of the department and providing the management of the department on this basis in order to achieve efficient management of these processes within digital applications.

Many processes at the departmental level are well regulated and should not involve any difficulty in their implementation. However, many education programs that run in parallel, numerous requirements for teachers specified in effective contracts, increased workflow, an increase in the number of students, and a significant increase in the number of spontaneously arising tasks results in the loss of manageability and reduced quality of training of graduates.

In this regard, there is a suggestion to create a complex regulatory management system of the department which should ensure the implementation of all regulated processes, that is, processes with meaningful, organizational, informational and temporal definiteness.

Within the scope of the regulatory management system, efficient interactive communication between the teacher and the student is made possible.

The proposed system will make it possible to systematically monitor the work and make this process transparent to the administration of the department, which will allow it to exert timely managerial influences.

In addition to the regulated tasks, the employees of the department have to participate in the implementation of various temporary projects and perform many spontaneously arising works.

These processes cannot be regulated in advance, yet they account for a considerable part of work effort of employees of the department. In order to achieve efficient implementation of these processes, the departmental automation system should

include the project management subsystem and the scheduling subsystem which would integrate all categories of departmental processes: regulated, scheduled, and unscheduled.

7. Project management system of the department

Except fairly well-defined tasks that are directly related to the educational process, other activities are also carried out at the department; the processes of these activities have no functional well-established nature, but depend on a wide variety of factors.

For example, the processes associated with research activities at the department should be generally classified as the project activity, which is characterized by specific distinctive features. First of all, it is the uniqueness of the result and the limited time frame for implementation.

To date, many systems have been created that focus on managing various types of projects. However, the selection of an adequate system of automation of project management often becomes an insoluble problem.

The thing is that a considerable part of such systems is focused on management of major construction projects and other projects on a similar scale, and is poorly adapted to solving the tasks at the departmental level.

Another part of the systems that are currently positioned held out as systems of flexible project management, are not such systems in their nature and relate more to scheduling systems based on time intervals, which are usually referred to as operational management tasks in management.

The purpose of such systems is the rational distribution of works among specified short time intervals. That said, it does not matter what category of processes these works belong to, functional or project works.

They can be successfully used in the implementation of a purely functional regulated activity with due consideration of randomly arising unforeseen problems.

The main advantage of such systems is their simplicity and fairly low cost. However, since such systems are successfully used not only in project management, it would be more correct to hold them out as a separate class of systems.

Such a distinction should bring more clarity to the possibilities and purpose of both project management systems and scheduling systems.

It is necessary to include subsystems that are classified both among the project management systems and among the scheduling systems, in the integrated management system of the department.

8. Operational management system of the department.

A considerable part of departmental activity can be presented in the form of predictive defined processes and long-term processes of the project nature, for which an efficient plan can be developed, and which will be implemented in accordance with this plan.

The relevant subsystems referred to above will be used for the management of these processes.

However, in practical activities of a modern department, it is often necessary to solve many unforeseen and spontaneously arising tasks.

This is due to the ever-increasing complexity of environment of the department.

Today, the number of accidental external effects on departments has become so large that they should be regarded as a fixed factor that determines the department's operation. The management system of the department must provide for the tools intended for the regulation of these impacts and their coordination with the main processes at the departmental level.

9. Individual work stations for students and staff members

Most subsystems described above imply continuous interaction between students, teachers and the administration of the department.

In order to achieve organization of such interaction, the integrated management system of the department should include a subsystem within which a set of individual computer work stations of all categories of system users (or personal user accounts) will function.

It is planned to develop work stations for all categories of users as part of the designed system: student; teacher; Head of Department etc.

The student's workplace should provide the opportunity for him to apply to the departmental knowledge base, work programs of the disciplines he studies, content, assessment tools for self-examination, etc.

An important function of a student's workplace consists in providing an interface for posting student works and documents confirming any form of student activity.

The workplace of a teacher at the department will also provide the opportunity to solve many diverse tasks. The following priority tasks should be considered: formation and development of the departmental knowledge base; formation and adjustment of work programs of disciplines; formation of the content of the departmental support system of the educational process, etc.

The information contained in the teacher's personal account will be used to establish the teacher's rating in accordance with the requirements of the effective contract.

The functionality of other work stations should be gradually tried and tested.

4 Conclusions

Due to the proliferation of SMART ideology in modern education, changes in the structure of information processes in university departments can be observed at present. Moreover, there is an ongoing rapid increase in the volume of the information content in all fields of knowledge.

Increasingly more complex educational activity of the department requires the creation and continuous development of digital applications that would support all areas of activity of the department.

The implementation of a set of such applications will make it possible to justifiably use the concept of "smart department", the activities of which are supported by a comprehensive range of modern digital technologies.

Research allowed substantiating the composition and the content of the conceptual model. It should include the following components:

1. Computer knowledge base (CKB) of the department.
2. Computational models of work programs of disciplines (WPD)
3. Digital learning support system
4. Educational process planning system at the level of departments
5. Document management at the department
6. Regulatory management system of the department
7. Project management system of the department
8. Operational management system of the department
9. Individual work stations for students and staff members

Evaluation of the Top-Priority Directions of Development of the Program "Digital Economy" in Regions of the Russian Federation

Marina R. Efimova, Tatyana A. Pershina, and Ekaterina A. Dolgikh

Abstract Social and economic development of any country depends largely on digitization. The digital form of information replaced informatization—in the form of Big Data—which influenced the economic processes of each country and its subjects. This paper is devoted to the global issue of digitization, which is very important for development of each country's economy. The authors consider the position of regions in the conditions of digitization and development of the program "Digital economy in the Russian Federation" and built an integral indicator for evaluating the technological readiness of regions for the digital economy, based on which groups of regions with similar values of the aggregated index are distinguished. Special attention is paid to multi-criterial groups for evaluating the level of development of own program of development of the digital economy for federal districts. Structural analysis is used for evaluating the main barriers for development of the program "Digital economy" in regions and country on the whole. The obtained results could be used by statisticians, economists, and sociologists for studying the top-priority directions of development of each group of regions.

1 Introduction

Based on the data of the International Telecommunication Union (ITU), the authors calculate the indicator "Index of development of information and communication technologies", which shows achievements of countries from the position of development of information and communication technologies. Russia is ranked 44th (among 167 countries), which shows insufficiently high level of development of its technological potential. For achieving higher positions, it is necessary to evaluate the development of subjects of the Russian Federation within the program "Digital economy". This program is aimed at creation of a developed eco-system, in which Big Data will play an important role in all spheres of the socio-economic activities. It is important to assess regions' readiness for digitization and development of certain programs within each subject of the Russian Federation [1].

The key aspects of development of the program are training of personnel for the digital economy, development of digital security, implementation of digital technologies in all spheres of activities, and development of state management in the conditions of digitization.

2 Methodology

Development of the program "Digital economy" is directly connected to regions' technological readiness. An important stage in analysis of the subjects is integral evaluation of the "Index of region's digital readiness" [2]. Multi-criterial evaluation with the help of this index covers a lot of indicators, which are grouped according to the aggregate characteristics: readiness for the digital economy of population, organizations, and state management [3].

The aggregated indicator of region's digital readiness allows determining the position of each region in the ranking by the indicator, determining the ranking of the subjects by each group of the indicators, and grouping the regions by similar values of the indicators of readiness for the digital economy [4].

For each group of the indicators (component), the authors calculate the index of digital readiness. Calculation of each large group of the indicators of readiness of regions for the digital economy is based on calculation of direct average from the normed values that are included in the corresponding blocks of the indicators [5–7].

Linear scaling [8] is used for norming the values—a normed private indicator is calculated by dividing the difference between the current level of the indicator and the minimum/maximum value in total, depending on the influence of the indicator, by the scale of variation in total.

The values of the index vary from 0 to 1—the higher the indicator, the higher the region's readiness for the digital economy.

Determining the values of large groups of the indicators for each region allows performing a general evaluation of the subjects' distribution by the value of aggregated indicators of technological readiness for the digital economy of population, organizations, and state management [9].

Aggregated evaluation of regions' technological readiness for the digital economy is calculated with the help of direct average of the normed values of integral values of the groups of indicators, which are readiness for the digital economy.

As a result of evaluating the integral indicator, a typologization of regions by technical equipment is created, with division of regions into three groups: "Low level", "Medium level", and "High level". This grouping allows evaluating the regions of the Russian Federation for further preparation of the differentiated measures for their development.

Having evaluated the technological readiness regions for the digital economy, it is necessary to analyze each federal district in view of analysis of the indicators provided by the analytical center under the Government of the Russian Federation in the statistical report that was prepared based on a survey "Current development of projects in the field of digital economy in the regions of the Russian Federation" [10].

Main point of the survey:

- Regional program of development of the digital economy;
- Region's top-priority end-to-end digital technologies, which are to be implemented;
- region's top-priority spheres of activities, in which digital technologies are to be implemented.

Based on the results of the survey of the level of development of the program of digitization in regions, grouping within the federal districts is performed. 79 regions have provided reports on top-priority spheres of activities and end-to-end digital technologies that are to be implemented.

The results for the following end-to-end digital technologies are provided:

- Big Data;
- Wi-Fi;
- blockchain;
- industrial Internet;
- neurotechnologies and AI;
- new production technologies;
- components of robotics and sensors;
- technologies of virtual and alternate reality;
- Internet of Things.

These indicators and their values are presented in the form of multi-criterial grouping for federal districts.

Based on the survey, groups are built for the top-priority spheres of digitization, with distribution by federal districts, and their ranking is performed with the help of direct average by ranks for each federal district.

Also, structural analysis of a group of barriers is performed for determining the main problems that hinder the development of the program "Digital economy" in Russia.

3 Results

Indicators of readiness of the subjects for the digital economy are shown in Table 1.

Based on the distinguished components, the leaders and outsiders among regions by the values of enlarged components in 2017 are determined (Tables 1 and 2).

Moscow and St. Petersburg are the leaders by readiness of organizations and population for the digital economy. St. Petersburg is the leader by the first components, and Moscow is the leader by the second component.

Analysis of the subjects with low values of the aggregated indicator for the groups that characterize readiness for the digital economy showed that the outsider is the Republic of Dagestan (Table 3).

Based on the obtained values of integral evaluation of region's readiness for the digital economy, a typologization of the subjects of the Russian Federation is performed. It allows determining regions with high, medium, and low levels of readiness for the digital economy (Table 4) [11].

Table 1 Indicators that characterize the subjects' readiness for the digital economy (Federal State Statistics Service)

Group of indicators that characterize readiness for the digital economy	Indicator
Readiness of state management	Share of population which interacts with government bodies and local administration via Internet (using official web-sites and portals of state and municipal services) (%)
	Share of population which uses Internet for obtaining state and municipal services (%)
Readiness of organizations	Share of organizations that use PC's (%)
	Share of organizations that use Internet (%)
	Share of organizations that have web-site (%)
	Number of PC's per 100 employees
	Share of organizations that use specialized software (%)
	Share of organizations that use electronic document turnover (%)
Readiness of population	Share of households with PC (%)
	Share of households with Internet access (%)

Position in the ranking	Readiness of state management	Readiness of organizations	Readiness of population
81	Zabaykalsky Krai	Saratov Oblast	Tomsk Oblast
82	Kostroma Oblast	Samara Oblast	Kurgan Oblast
83	Magadan Oblast	Republic of Buryatia	Republic of Mordovia
84	Jewish Autonomous Oblast	Sevastopol	Chechen Republic
85	Chukotka Autonomous Okrug	Republic of Dagestan	Republic of Dagestan

Source Compiled by the authors

Eleven subjects of the Russian Federation have "High level" of readiness for the digital economy by the aggregated index. This group includes two subjects of the Central Federal District, three subjects of the Volga FD, one subject of North Caucasian FD, one district of Siberian FD, and two districts of Ural FD. This group is the smallest of all groups.

The group with low level of readiness for the digital economy by the aggregated index includes 11 subjects, which represented all Federal Districts. Republic of Dagestan confirms its low position by the aggregated index, as by two out of three components it is the last one in the ranking by the indicators that characterize technological readiness of regions for the digital economy.

Table 4 Distribution of regions by the aggregated indicator of readiness for the digital economy

Level of readiness for the digital economy	Subjects
High (11)	Republic: Ingushetia, Bashkortostan, Tatarstan, Tyva, Moscow, St. Petersburg Oblasts: Voronezh, Moscow, Orenburg Autonomous Okrugs: Khanty-Mansi, Yamalo-Nenets
Medium (55)	Republics: Karelia, Komi, Adygea, Kalmykia, Crimea, Kabardino-Balkar, Karachay-Cherkess, North Ossetia-Alania, Mari El, Udmurt, Chuvash, Altai, Khakassia Oblasts: Belgorod, Bryansk, Vladimir, Ivanovo, Kaluga, Kursk, Lipetsk, Ryazan, Smolensk, Tambov, Tula, Yaroslavl, Arkhangelsk, Vologda, Kaliningrad, Leningrad, Murmansk, Novgorod, Astrakhan, Volgograd, Rostov, Nizhny Novgorod, Penza, Samara, Saratov, Sverdlovsk, Tyumen, Chelyabinsk, Omsk, Amur, Magadan, Sakhalin Krais: Krasnodar, Stavropol, Perm, Altai, Krasnoyarsk, Kamchatka, Primorsky, Khabarovsk; Nenets Autonomous Okrug
Low (19)	Republics: Dagestan, Chechen, Mordovia, Buryatia Sevastopol, Zabaykalsky Krai, Jewish Autonomous Oblast, Chukotka Autonomous Okrug Oblast: Kostroma, Orel, Tver, Pskov, Kirov, Ulyanovsk, Kurgan, Irkutsk, Kemerovo, Novosibirsk, Tomsk

When working on the differentiated measures of development of regions in the digital economy, it is possible to use the results of analysis of rankings of separate regions.

Within development of the program “Digital economy” in regions of the Russian Federation, a survey was conducted in regional executive authorities; it aimed at studying implementation of regional programs of digital technologies (30.04.2019 to 17.05.2019).

Based on the regional survey, a grouping of the values for the federal districts is performed (Table 5).

Out of 79 regions in the survey, only 32 regions (40%) have a regional program of development of digitization (finished or in the process of development).

Let us consider the structure of distribution of federal districts by the state of development of the digitization program (Fig. 1).

Analysis of the structure shows that the highest share of regions that have already developed or are in the process of development of their own program of digitization is in the Siberian Federal District (56%), the North Caucasian Federal District (50%), and the Ural Federal District (50%).

Evaluation of the top-priority end-to-end technologies in the federal districts is shown in Table 6.

Table 5 Distribution of regions in federal districts by the level of development of the digitization program

Federal district	Respondents	Development of the program	
		In development	Absent
Central FD	16	6	10
Northwestern ΦO	11	4	7
Southern FD	8	3	5
North Caucasian FD	6	3	3
Volga FD	13	5	8
Ural FD	6	3	3
Siberian FD	9	5	4
Far Eastern FD	10	3	7
Total	79	32	47

According to the regions, the top-priority directions of implementation are as follows: Big Data (66.7–100% of regions for certain federal districts); industrial Internet (12.5–88.9%); neurotechnologies and AI (20–83.7%); wi-fi (37.5–77.8%).

A special role in analysis of the digital economy in Russia is evaluation of the spheres that are ready and use digital technologies (Table 7).

According to the survey, the top-priority sphere of digitization is healthcare (60 regions out of 79). There are differences in selection of priorities in the regions of the Russian Federation. Thus, in the North-Caucasian Federal District, the necessity for digitization of healthcare is noted by 3 subjects (60% of the respondents), and in the Siberian Federal District—9 subjects (100%).

In the Central Federal District, the top-priority sphere of digitization, apart from healthcare, is urban environment—11 regions (68.75%).

Most of the respondents of the North-Western Federal District named the following spheres: healthcare, transport, and housing and utilities sphere (81.8% of the regions of the Federal District).

The same spheres are important for the subjects of the Southern Federal District (62.5% of the subjects). The top-priority sphere of digitization is "personnel and education" (75% of the studied regions).

For most of the subjects of the North-Caucasian Federal District, the most important spheres of digitization are transport, urban environment, healthcare, personnel, and education (60% of the subjects).

As for the Volga Federal District, the top-priority spheres are healthcare and personnel & education (84.6%).

In the Ural Federal District, the leading sphere by importance of digitization is urban environment—as noted by all regions.

All studied subjects of the Siberian Federal District see healthcare as the top-priority sphere.

In the Fast-Eastern Federal District, most of the subjects see urban environment and healthcare as the top-priority spheres (80% of the respondents).

It should be noted that subjects of the most federal districts do not consider digitization of the ecological sphere to be necessary. It is of top priority only in one subject of the Ural FD and three subjects of the Central FD.

As a result of evaluation of federal districts, ranks for the top-priority spheres of digitization were assigned—with the help of direct average (Table 8).

The top-priority sphere is healthcare, then comes urban environment. The energy sphere has the lowest share of digital technologies (14th position). The sphere of education, which is the basis for training of personnel with digital competencies, is ranked 3rd by priority [12].

In August–September 2019, there has been conducted an analytical survey among regional authorities regarding the issues of barriers in development of the digital economy in regions of the Russian Federation. Regional authorities of 70 regions participated in the survey (Table 9).

Table 8 Ranks of the top-priority spheres of digitization

Top-priority spheres of digitization	Ranks
Healthcare	1.00
Urban environment	2.00
Personnel and education	3.00
Transport	4.00
Housing and utilities sphere	5.00
Culture and tourism	6.00
State management	7.00
Agriculture	8.00
Construction	9.00
Industry	10.00
Other	11.00
Ecology	12.00
Communications	13.00
Energy sphere	14.00

Table 9 The structure of barriers in development of the digital economy in 70 regions in August–September 2019, %

Groups of barriers	% of the total number of answers
Training of personnel for the digital economy	18.8
Normative and legal barriers	17.3
Administrative and managerial barriers	16
Level of development of the information infrastructure	13.9
Information barriers	11.1
Barriers in the sphere of end-to-end digital technologies	6

According to the regional executive authorities, the biggest problem is training of personnel for the digital economy (18.8%) and normative & legal barriers (17.3%). The lowest barrier is the one in the sphere of end-to-end digital technologies (6%).

4 Conclusions/Recommendations

The performed research allowed determining groups of regions that are homogeneous by the level of readiness for the digital economy. The compiled rankings by the integral indicator of readiness for digitization allowed determining the leading countries. Evaluation of the state of development of own regional program "Digital economy" allowed evaluating federal districts with the highest potential for digitization. Readiness of the regions of the Central FD in 2017 coincides with the level of development of own program "Digital economy". Based on the results of evaluation of the most popular end-to-end digital technologies, most of the subjects note that Big Data play an important role in the analytical methodology that is necessary for substantiating the directions of development of the country's economy on the whole.

The most developed spheres of activities use digital technologies, which allows evaluating the opportunities for applying the additional measures for increasing the positions of other spheres—in particular, education. Training of personnel with digital competencies allows strengthening the positions of other spheres of digitization, in view of the barriers on the path of achievement of complex development of the program "Digital economy" in Russia.

The government of the Russian Federation should use experience of countries that are leaders in this sphere during development of the policy in the sphere of digitization.

Objective Changes in Business in the Conditions of Economy Digitization

Larisa S. Shakhovskaya and Galina D. Kamaeva

Abstract This article introduces business changes due to the development of the digital economy. The differences between the digital economy of today and the pre-digital era are identified and justified, the main business models are reviewed and classified, and the main drivers of changes in modern business are highlighted. The analysis showed that in all definitions of the concept of a business model, it is common that the authors use a process (rather than a functional) approach to management, and include in the business model the key factors by which the company creates value for the client and provides most competitiveness, relying mainly on environmental factors. If you look at the digital economy from the point of view of new business models, the main idea is the transition from a product to a service model, in which the object of sale and consumption becomes not only and not so much the product itself, but the services provided to the user in connection with this product. In traditional business models, there are factors that limit the ability of effective interaction between market participants. From which we can conclude that the transition to a digital economy model throughout the world and, in particular, in Russia and the Volgograd region is accompanied by fundamentally new, qualitative changes in socio-economic relations at the level of business structures. Traditional businesses have to change and learn to use modern technology to remain competitive and survive. Indeed, using digital technologies, enterprises will be able to achieve increased labor productivity, reduced production costs, improved quality, accelerated the process of new products entering the market.

1 Introduction

Topicality. The invention of the Internet led to large changes in the world—which are called informatization. It covered almost all spheres of human activities, including economy and led to emergence of the digital economy, which, in its turn, changed the traditional business. New production models appeared which do not limit the possibility of effective interaction of market participants. **Expedience** studying this issue is justified by the necessity for determining perspective models of the digital economy formation.

The study of the problem. The problems of business, digital business, and business models are very important for development in Russia and abroad. Bill Gates was one of the first to speak about development of business in the digital environment. Others include Henry Chesbrough, Alexander Osterwalder, and Yves Pigneur. Digitization and the digital economy were studied, among others, by B. Garifullin and I. Strelkov.

Novelty of this research consists in substantiating the necessity for creating new forms of organization of business due to digitization of economy; thus, it is possible to distinguish criteria for comparing the platform and traditional business models and determine the examples of platform models at the regional level.

The purpose of this paper is to analyze digital business and the approaches to classification and comparison of the advantages of various models of doing business in the conditions of digitization of economy.

The following tasks have to be solved for this:

1. Distinguishing the main drivers of the change of business in the conditions of economy digitization;
2. Determining and analyzing the history of development of the term "digital business";
3. Analyzing and comparing business models of the modern and pre-digital economies.

Theoretical significance consists in developing the unified methodological approaches to formation of criteria for comparing the platform and traditional business models.

Practical significance consists in the possibility to apply the proprietary theoretical approaches in practice when distinguishing the platform and traditional business models at the regional level.

2 Main Part

In 1999, Bill Gates, an American business magnate, software developer, investor, and philanthropist, specified the ideas of the information revolution in his book "Business @ the Speed of Thought". He thought that development of IT and Internet,

in particular, influences all aspects of society's life—especially business, which has to react to the changes in economy instantaneously. He wrote, "In the future, two types of companies will remain—companies that are present on Internet and companies that are out of business" [1].

It is hard to argue with this, especially now—in 2020. Global expenditures of companies for digital transformation continue growing by 16–18% annually, according to the international analytical agency IDC. As of year-end 2017, their volume exceeded USD 1.3 trillion, and it will reach USD 2.1 trillion in 2021. A large share of expenditures for digital transformation (USD 662 billion) will account for technologies that support new or expand the existing operational models. The second largest sphere of investments (USD 326 billion) will be technologies, which will transform the interaction with customers, allowing for loyalty management and creation of individual offers [2].

The main difference between the present-day digital economy and the pre-digital age is that customer is actively involved in the life cycle of a product that is built based on the digital model. This is due to the fact that a product or service that is sold to the customer is equipped by electronic and devices of initial information reading. Besides, it the digital economy is considered from the point of view of new business models, the main idea is transition from the product to the service model [3].

What is the product and service models? The product model of any company envisages that company manufactures and develops its products, which are then sold to a large number of customers without any change – as a final product [4]. The service business model is based on service contracts. Service contract is a complex offer of a product and connected services, which creates additional value in the moment of sale and in the course of the product's life cycle. The object of sell and consumption in the service model is not so much the product as the services that are provided to the customer for this product—maintenance and repairs, as well as others (the purpose is not vacuum cleaner, the purpose is cleanliness after it). Thus, Rolls-Royce does not sell aviation engines—it offers a TotalCare service, within which only hours of exploitation of each engine are paid for [5].

Thus, three drivers of changes are obvious:

1. Involving customer in the process of exploitation at all stages of the life cycle of product/service;
2. Using information as a commercial object;
3. Transition from the product model to the service model.

3 History of Appearance of the Term "Digital Business"

A research and consulting company Gartner defined "digital business" as a new model of business that covers people/business/things and is spread around the world by means of using IT, Internet, and all their features, with effective personal services "any time any place". Experts of Boston Consulting Group think that digitization is usage of the opportunities of online communication and innovative digital technologies by

all participants of the economic system—from individuals to large companies and states [6]. However, this term appeared even before this 2014 definition.

In 2000, J. Linder and S. Cantrell focused on the main method of creation of value, which could be represented in different ways: through components of business model, operational model, or model of change. The model of change is the main way of company's changing in time, in order to remain profitable. Thus, the authors presented a classical business model as a static scheme, which describes the current state of a company, which has to be supplemented by a model of changes that ensure preservation of the achieved level of profitability in the future. The main driver of these changes is digital transformation of business based on technological innovations.

In 2006, Henry Chesbrough introduced probably the widest notion of a company's business model. He defined it as a "method used by a company to create value and obtain profit". In 2008, company's business model was defined by H. Werthner and R. Mustafa: "conceptual description of company's buying and selling goods and services and making money". Unfortunately, such general description fits any description of a company, including the one that does not convey its essential features and does not form a model. Such general approach probably envisages unjustified refusal from using the theory of management in favor of generalization and dissemination of the practical experience of entrepreneurial activities. In this case, there are no chances for an effective combination of the theory and practice of management—and the above definitions need to be clarified.

The most popular business model is the one offered by Swiss business analysts Alexander Osterwalder and Yves Pigneur—Business Canvas Model, within which the authors distinguished two groups of the main factors that form value and ensure competitiveness of a modern company. The first "incoming" group includes resources, partners, and processes.

The second group ("outgoing") describes customers: target groups of consumers, distribution channels, and technologies of interaction with customers.

Business Canvas Model includes also two groups of the most important financial indicators of company's activities—structure of expenditures and flows of revenues, which largely determine the company's competitiveness.

Alexander Osterwalder and Yves Pigneur defined business model as a conceptual tool that contains a "set of object, notions, and their interconnections aimed at expressing a specific company's business logic" (Rozeia Mustafa, Werthner 2011); thus, the authors' model is based on a detailed business idea, with the emphasis on the company's external environment. According to them, harmonious "involvement" of the company in its external environment (not factors of the internal environment—culture, structure, etc.) ensures the company's competitiveness. However, any model should distinguish the most important elements of the system and ignore the insignificant ones, and the modern theory of strategic management states that the company's destiny is determined not only by external but also by internal factors (strategy, culture, structure, etc.), and in the situation of high uncertainty and turbulence of the economic environment success is also predetermines by flexibility of reaction to unpredicted treats and new opportunities. That's why the issue of supplementing

the Alexander Osterwalder and Yves Pigneur's business model with the models of company's internal environment (McKinsey 7S, PEST atom, etc.) becomes very topical; also, when developing a new business model, it is necessary to use the method of real options, which allows setting the possibility of flexible reaction to unexpected events of the future in the strategic solutions [7].

In 2008, researchers from Brunel University defined organization's business model as an "abstract presentation of organization—conceptual, textual and/or graphic—from all interconnected structural, operational, and financial mechanisms, developed by the organization, and all products and/or services that the organization offers based on these mechanisms and that are necessary for achieving the strategic goals and tasks" [3].

In all the above definitions of business model, the authors use the process (not functional) approach to management and include in the business model the key factors, which are used by the company for creating value for the customer and ensuring its competitiveness, based primarily on the factors of the external environment, which changes—in the modern conditions of economy's globalization—acquire more turbulent character.

4 Comparative Analysis of Business Models

At present, old and ineffective business models in a range of spheres (banking, telecommunications, insuring, and logistics) are replaced by new models, which conform to the demands of modern consumers. Thus, appearance of mobile devices and development of mobile apps led to growth of popularity of so called "platform" business models.

There are different approaches to classification and comparison of various models of doing business. However, for the purpose of comparative analysis, business models in the modern economy should be divided into traditional and platform. Platform business models create value for customers by means of usage of digital technologies, which allow for interaction of various participants of the economy in real time, with usage of electronic & digital channels of communication, which ensure equal access of all participants to information and which ensure information's correctness. Thus, opportunities for misuse of monopolistic position and unfair competition are reduced, and trust in economy grows.

A vivid example of a platform model in Volgograd, Russia is YandexTaxi. Local dispatch services became unprofitable, as most of orders are covered by Internet aggregators and federal networks. Certain dispatch services survive by reducing the personnel and using the services of outsource call centers.

In order to create value, the traditional business model used a link between customer—taxi passengers, and the person providing a service—taxi driver. This link was a call center, which accepted and processes the orders and feedback. The platform business model eliminated the medium link—call center—replacing it with

Table 1 Comparison of companies' business models in the digital economy

Criteria of business models	Traditional business model	Platform business model
Method of interaction of the market relations' participants	Chain (via intermediaries)	Direct (direct contact with consumer)
Additional limitations	Yes	No
Expenditures required for starting business	Medium	High
Buyers' trust	Low	High

a new and more effective tool—mobile app, which allows reducing saving time and money and which thus adds value for all participants of these relations.

It is necessary to distinguish criteria for comparing the platform and traditional business models.

The criteria of companies' business models in the digital economy:

1. Method of interaction of participants of market relations;
2. Additional limitations;
3. Expenditures required for starting business;
4. Buyers' trust (Table 1).

There are factors in the traditional business models that limit the possibility for effective interaction of the market participants. For example, customs limitations did not allow ordering an item to Russia from China with minimal expenditures. The expenditures would be so high that the purchase became inexpedient. However, AliExpress allowed lifting up the territorial limitations and made the trade mutually profitable.

The digital model of economy will allow implementing the following:

1. Development of completely new types of business that are parts of the international production chains.
2. A new model of attraction of investments in economy.
3. A more effective model of management in the healthcare and social and educational spheres.
4. Increase of effectiveness of state management [8].

5 Conclusions

Thus, transition to the model of the digital economy in the world, and in Russia and Volgograd Oblast, in particular, is accompanied by new qualitative changes of the socio-economic relations at the level of business structures. Traditional companies have to change and learn to use modern technologies, in order to preserve their competitiveness and to survive in a very turbulent and aggressive competitive external environment. Using digital technologies, companies will be able to increase labor

efficiency, reduce product cost, improve quality, enter new markets, and forecast their activities in the current market segment.

The performed research allows forming and analyzing the gathered information, which allows determining the differences between the traditional and platform business models.

Characteristics and Causes of Commission of Crimes by Foreign Nationals Who Served a Custodial Sentence

Olga A. Vetrova, Petr K. Dolzhikov, Sergei A. Bukalerov, and Bakitkul R. Sembekova

Abstract *Purpose*: the purpose of research is to examine the legal status of foreign nationals who are released from imprisonment, in respect of whom decisions are made by a competent federal executive body on the undesirability of their stay (residence) in the Russian Federation, with a view to improving legislation on the legal status of foreign nationals. *Design/methodology/approach*: the goal of research was achieved through the use of general scientific and specific scientific research methods, comprehensive, complete and objective analysis of statistical data, as well as domestic and foreign statutory regulations existing in the law enforcement practice. *Findings*: the conclusions about the uniform trends in domestic legal thought and law-making practice in respect of criminal activity of ethnic groups conducting their activities both in and outside Russia have been formulated. The need to reintroduce the concept of "recidivist" into penal legislation, and, accordingly, enhance legal measures against foreign nationals who served a custodial sentence, has been justified. *Originality/value*: The poorly elaborated migration policy allows international crime to invade our state, which is the main external cause of the increase in crimes committed by foreign nationals. Studying quantitative and qualitative characteristics of recidivism of foreign nationals contributes to the development of a crime prevention system, which exerts significant influence on the decrease in recidivism, reduces the burden on the penal system, prevents the criminalization of an individual and ultimately contributes to a decline in crime in society.

1 Introduction

The criminological experimental study of foreign crime finds that the scale of illegal activities of ethnic groups allows classifying them among the multifunctional criminal gangs that implement their criminal intentions both in and outside Russia. Taking into consideration the ever-increasing competences of members of the organized criminal group from among foreign nationals, their high degree of conspiracy, their privacy from the public eye, the presence of language barriers, it may be concluded that ethnic organized criminal groups appear to be fairly closed to law enforcement agencies. Therefore, a decrease of 7.9%, say, in the number of crimes committed by foreign nationals for the period from January till May 2019, as compared to the same period in 2018,[1] with a multiple increase (from 1.5 to 7 million or more) in the number of illegal immigrants, is not realistic, and thus, is mainly indicative of the ineffectiveness of fight against crime committed by foreign nationals.

2 Materials and Method

The authors of the research used traditional methods of legal analysis and legislative techniques.

Based on elaborated criteria, the authors assessed the quality of Russian statutory regulations providing protection from sexual information disseminated through the use of information and communication technologies. They gave a definition of the social dependence of legal prohibitions of certain activities in a virtual environment. The available methodological and analytical tools are a result of the development of well-known and time-tested research techniques in legal science.

3 Results

In this regard, we emphasize the following criminogenic factors that exert enormous influence on the criminological characteristics of crimes committed by foreign nationals:

[1] URL: https://xn--b1aew.xn--p1ai/reports/item/17236961/ (Accessed: 15.10.2019) [1].

- political and domestic causes, such as aggravation of international controversy, aggravation of migration situation, lowered passport and visa requirements, forced migration of enormous flows of refugees, uncontrolled movement of illegal migrants and, eventually, high rate of criminal migration within Russia; lack of focus on stabilization of Migration Policy in our country and adoption of legislative provisions regulating the legal relations in migration;
- economic causes: establishing connection between the economies of different countries and, in this regard, the emergence of organizations from other countries, carrying out criminal activity, including with the aim of legalizing illicit money capitals in the economic space of our country; growth in demand for cheap foreign labor force, which results in uncontrolled increase in the migration stream, including from the CIS countries (Uzbekistan, Tajikistan, Moldova, Kyrgyzstan, etc.);
- demographic and social causes: prolonged social and economic restructuring in the CIS countries, which eventually resulted in the emergence of citizens who lost their jobs and live in poverty, which often urges people who are trying to find some means of living, to commit a crime, and to repeat crimes; this leads to a decline in morality; concentration of a vast number of foreign nationals in major built-up areas of the Russian Federation;
- low efficiency of law enforcement agencies: poor professional qualifications of employees of various services of police agencies; lack of methodological scientific research results, regulating the activity of operational subdivisions of offices of internal affairs bodies in this area; the lack of proper interaction for the detection and prevention of migration crimes between public authorities of various states.

In our opinion, the intensification of illegal activities of international criminal gangs, activity of terrorist organizations in the international arena, related to the aggravation of ethnic conflicts, strengthening of positions of terrorist organizations in the international political arena, international controversy, creation of profitable crime business in the field of illegal migration, and, eventually, inability of antiterrorist organizations to stand up against transnational crime and terrorism, are the main criminological factors that influence an increase in the number of crimes committed by foreign nationals arriving in our country as refugees and migrants.

We shall give consideration to general state of affairs of convicts in the problem under study in arrears—2018, and in general for the past five years based on statistics of the Judicial Department under the Supreme Court of the Russian Federation. It has been established that no increase in the number of crimes committed by foreign nationals and stateless persons has been observed in our country over the recent five years.[2] According to statistics, men commit much more crimes than women. Thus, for example, in 2018, there were 23,164 men (see Fig. 1), and 2157 women out of the total number of convicted and sentenced migrants (see Fig. 2).

[2]Official website of the Judicial Department of the Supreme Court. Overview of activities of general jurisdiction courts and magistrates in 2018 (Accessed: 15.10.2019) [2].

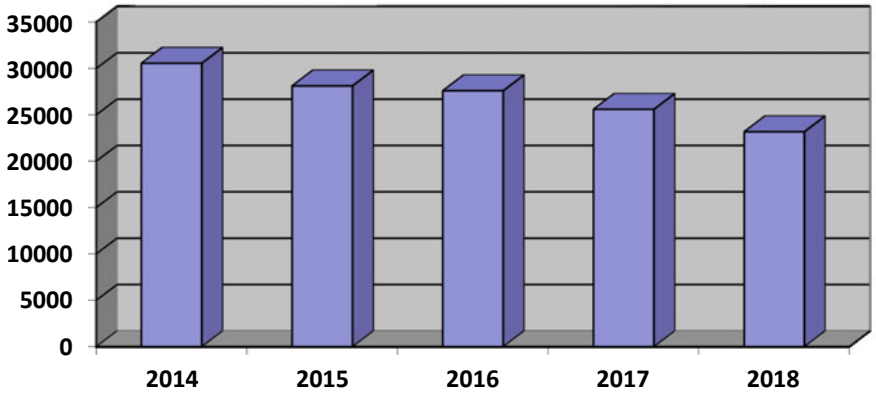

Fig. 1 Total number of foreign nationals convicted in Russia for the period from 2014 till 2018 (thousand people)

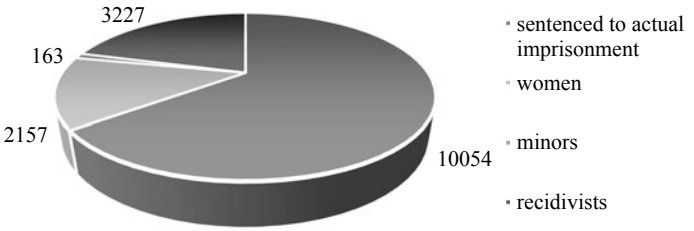

Fig. 2 Quantitative characteristics of foreign convicts for 2018, through the example of certain categories of persons

Main types of crimes committed by foreign nationals:

(1) crimes against person—2076 people sentenced in 2018; moreover, such crimes as murders, willful infliction of grievous bodily harm, willful infliction of minor bodily harm, infliction of severe bodily injury or moderately severe bodily injury, were committed by the majority of foreign convicts;
(2) crimes against public security and public order in 2018—388 people. Crimes against public health over the past 2018 year—3192 people (17.8% of the total number of foreign convicts). Crimes related to illegal trafficking in narcotic drugs and psychotropic substances, as well as illegal arms trafficking, are the most numerous crimes committed by foreign convicts in Russia. The statistics of the Judicial Department under the Supreme Court of the Russian Federation states that migrants are divided into three categories: citizens of the CIS states, foreign nationals, and stateless persons. Most convicts are from the former

Table 1 Ratio of the number of foreign convicts to the total number of convicts in the Russian Federation (people) during the period from 2014 till 2018

Years	The total number of foreign convicts	Total number of convicts in the Russian Federation	In percentage ratio of the number of foreign convicts to the total number of convicts (%)
2014	30,558	719,305	4.25
2015	28,115	733,607	3.83
2016	27,589	741,329	3.72
2017	25,586	697,054	3.67
2018	23,164	658,291	3.52

CIS countries—2152 people, stateless persons—245 people, while the rest are foreign nationals from countries outside the CIS.

(3) crimes against property (assaults with intent to rob, robberies, fraud and blackmail, as well as larceny)—7370 people, representing 31.8% of the total number of foreign convicts;

(4) economic crimes (illegal use of trademark, illegal business operations, smuggling, illegal trafficking in precious metals, fabrication and use of false money or securities and illegal use of trademark)—224 people for the past period.

(5) crimes against the public order, such as falsification, fabrication or use of forged documents, national awards, stamps, seals and forms, as well as official bribery and management of illegal migration—1139 people, representing 4.9% of crimes committed by persons belonging to the category under consideration.

A total of 23,164 foreign nationals were sentenced in 2018 (see Table 1).

Statistical data confirm that foreign nationals commit the largest number of crimes in the Central Federal District of the Russian Federation. This is due to the fact that there is a majority of lending and financial institutions in these regions of our country, hence, enormous monetary funds are concentrated there.

Thus, although the rate of increase in the number of convicts is currently going down according to the statistics of the Judicial Department under the Supreme Court of the Russian Federation, the situation is different with recidivism. Compared to 2014–2017 and 2018, we might as well say that recidivism has been stable, except the last two years (see Table 2).

When we formulate quantitative and qualitative characteristics of recidivism of foreign nationals, it seems that currently there is a need to identify and carry out preventive registration of foreign nationals committing crimes in our country, and, primarily those persons who have no permanent source of income and are inclined to commit a crime, previously convicted persons, with Internal Affairs Agencies, as well as to enter information about such persons in other special investigative, criminological, and preventive registration records and information records.

Table 2 Quantitative characteristics of foreign convicts in 2014–2018 in the Russian Federation (people)

Years	The total number of foreign convicts	Out of the total number of foreign convicts			
		Women	Minors	Recidivists	Sentenced to actual imprisonment
2014	30,558	3,054	231	3,918	12,757
2015	28,115	2,696	204	3,822	12,166
2016	27,589	2,746	260	3,661	12,476
2017	25,586	2,368	205	3,352	11,305
2018	23,164	2,157	163	3,227	10,054

In our opinion, the dissolution of the Soviet Union, the implantation of the market economy in our country coupled with poorly elaborated migration policy, as a consequence of which transnational crime strongly invades our state, are the main external causes of the increase in crimes committed by foreign nationals. The market economy has emerged relatively recently in Russia, since the collapse of the Soviet Union in 1991, unlike European and American countries, where it has already proven its right to exist through the development of free competition and support of private business by the governments of these states. However, the secession of many republics from our multinational state was followed by the economic instability, which urges certain categories of citizens of currently foreign states to earn a living in the English Federation, including through crime. Migration flows which are scarcely ever properly monitored, also contribute to this state of affairs.

It must be admitted that the mechanisms of regulation of foreign labor force and migration management systems in general should be adequate and internally consistent. Iwakhniuk, I.V. believes that "the abolition of employment quotas for citizens of the CIS countries in favor of a reasonable combination of the competitive market of migrant labor and an organized recruitment of labor force for large and medium-sized enterprises through the conclusion of direct contracts with countries of origin and development of the infrastructure of the labor market could provide more flexible involvement of the resource of foreign labor force in the mechanism of the Russian labor market. The necessary control could be exercised through monitoring of the labor market and objective indices of employment and unemployment in the local community".[3]

In addition to the abovementioned causes of the increase in the rate of crimes committed by foreign nationals in our country, Balykov, V. N. points out the reasons that influence the increase in the crime rate related to migration, such as economic recession and decline in production, rising living costs, inflation, mass unemployment; privatization, growth of private enterprise, expansion of commerce, real estate market; formation and intensification of differences between new states which are former republics of the USSR, mediated by political and economic conditions, living

[3]Information and Analytics on the Migration Situation within the Russian Federation by Federal Districts [3].

standards, social instability, as well as negative population processes, for example, extinction and "ageing" of native population.[4]

The increased rate of the so-called ethnic crime is also promoted by visa free regime of entry of foreign nationals into the Russian Federation from the countries belonging to the Commonwealth of Independent States—Azerbaijan, Armenia, Belarus, Kazakhstan, Kyrgyzstan, Moldova, Tajikistan, Uzbekistan and Ukraine. On February 29, 2000, "Agreement between the Government of the Russian Federation and the Government of the People's Republic of China on visa-free party travels" was adopted, which in our opinion does not contribute to the anti-terrorist protection of the Russian Federation. At present, the Prime Minister Dmitriy Medvedev has approved the project of a new Intergovernmental Agreement between Russia and China on visa-free party travels. It appears that this agreement may facilitate the unimpeded entry of Chinese nationals into the Far Eastern District, which shares borders with China, for purposes of exporting English hardwood and unhampered introduction of genetically modified products in our consumer's market. How much longer can we make our country a springboard for world-scale experiments?

According to Article 6 of Federal Law No. 182-FZ of 23.06.2016 "About Bases of System of Prevention of Offenses in the Russian Federation",[5] prevention of offences occurs in the following areas: prevention of offences; development of the system of preventive registration of persons who are inclined to commission of crimes; countering illegal migration; increasing the level of legal literacy and development of legal awareness of citizens. In accordance with Part 2 of Article 6 of the abovementioned Federal Law, the primary areas of prevention should be implemented through identification, assessment and forecasting of criminogenic factors; detection and elimination of causes and conditions that contribute to antisocial behavior and commission of crimes, including resulting from social, racial, national or religious discord, etc.

In this regard, it should be mentioned that prevention of recidivism by persons who served a custodial sentence is not adequately developed in the law enforcement system of the Russian Federation. Thus, the "Instruction for the management of activity of Police Commissioners",[6] which defines the primary areas and management of activities of the Police Commissioner, refers providing assistance to institutions and agencies of the correctional system in the search for and apprehension of persons who have escaped from custody, persons who have evaded serving a criminal sentence (Paragraph 37.14), to the duties of a local police officer. In addition, in accordance with Paragraph 37.16. of Section VI "Duties of a Police Commissioner" of the specified Instruction, the Police Commissioner must be involved within the scope of his competence in exercising control (administrative supervision) over compliance with prohibitions and restrictions by persons released from detention that were

[4]Balykov [4].

[5]Federal Law of the Russian Federation No. 182-FZ of 23.06.2016 "About Bases of System of Prevention of Offenses in the Russian Federation". Rossiyskaya Gazeta, No. 139, 28.06.2016.

[6]Order of the Ministry of Internal Affairs of the Russian Federation No. 1166 of December 31, 2012. Moscow "Issues related to managing the activities of Police Commissioners". Rossiyskaya Gazeta, No. 65, 27.03.2013.

imposed on them by court in accordance with Federal Law No. 64-FZ of 06.04.2011 "On Administrative Supervision over Persons Released from Detention".[7] The Police Commissioner shall be obliged to check the persons belonging to this category at least twice a month, as well as at night time, if this is established by court order.

As for the changes in current legislation in respect of the legal status of foreign nationals in general, we would like to mention the positive changes in respect of definition of citizenship of persons staying within our state, and legal grounds in accordance with which foreign nationals have the right to stay and reside within our state. Thus, persons who fall within the scope of Chapter VIII.1 "Adjustment of the legal status of certain categories of citizens situated within the Russian Federation" of Federal Law No. 62-FZ of 31.05.2002 "On Citizenship of the Russian Federation"[8] (as amended and supplemented on 17.10.2019), who will not file an application for receiving recognition as citizens of the Russian Federation or conferment of citizenship of the Russian Federation until January 1, 2025, will have to leave Russia by April 1, 2025. Persons who fail to comply will be subject to deportation. This being said, the conditions and procedure of the conferment of citizenship of the Russian Federation are specified in Article 41.1 of this Law, Paragraph "e" of which reads: persons specified in Part 1 of this Article, can regulate their legal status based on the declaration of will to confer citizenship of the Russian Federation or to be granted a residence permit in accordance with Federal Law No. 115-FZ of July 25, 2002 "On the Legal Status of Foreign Nationals in the Russian Federation".[9] In accordance with Paragraph "e" of the Law, persons who received Russian Passport until January 1, 2010, whose citizenship of the Russian Federation was subsequently not ascertained by the authorized body in charge of affairs on citizenship of the Russian Federation, who possess nationality of a foreign state provided that they have no valid document certificating their right to reside in a foreign state, may qualify for the citizenship of the Russian Federation.

We would like to note that the legislator in the English Federation has so far not developed any special sanctions against foreign nationals who are released from imprisonment, in respect of whom decisions are made by a competent federal executive body on the undesirability of their stay (residence) in the English Federation. According to Paragraph 2 of Article 28 of Federal Law No. 114-FZ of 15.08.1996 "On

[7]Federal Law of the Russian Federation No. 64-FZ of 06.04.2011 (as amended on 29.07.2017) "On Administrative Supervision over Persons Released from Detention". Rossiyskaya Gazeta, No. 75, 08.04.2011.

[8]Federal Law of the Russian Federation No. 62-FZ of 31.05.2002 "On Citizenship of the Russian Federation" (as amended on 26.07.2019). Rossiyskaya Gazeta, No. 100, 05.06.2002 (as amended and supplemented, came into effect on 17.10.2019).

[9]Federal Law of the Russian Federation No. 115-FZ of 25.07.2002 "On the Legal Status of Foreign Nationals in the Russian Federation" (as amended on 19.07.2018). Rossiyskaya Gazeta, No. 140, 31.07.2002.

the Procedure for Leaving the Russian Federation and Entry into the Russian Federation",[10] the right to leave the Russian Federation may be restricted to foreign nationals from foreign countries if they were sentenced for commission of crimes within our territory until the serving (execution) of a sentence or until their release from punishment, except foreign nationals who were conditionally released from custodial sentence, if they had no material obligations to the injured party in accordance with the court's decision.

4 Conclusion

In view of the above, in order to control the recovery of funds by the service of court bailiffs, a suggestion has been made to establish a legislative administrative supervision over foreign nationals, against whom the administration of the penitentiary facility commences actions with judicial authorities for compensation for material damage, and to include this suggestion in Paragraph 5 of Part 2 of Article 3 of Federal Law No. 64-FZ of 06.04.2011 (as amended on 29.07.2017)[11]: "2. Administrative supervision shall be established… in respect of a person of majority age who is or was released from detention and has unexpunged or unspent convictions for the commission of the following offences: 5) causing material damage to citizens, public or private enterprises, institutions, organizations or their associations, or the property of a penitentiary facility in which a person who had been sentenced to imprisonment served his/her sentence".

Furthermore, in order to exercise control over foreign nationals released from detention, in the face of a steady increase in the rate of recidivism which indicates increased threat constituted by this category of citizens, as well as in order to exercise temporary restrictions of their rights and freedoms pursuant to court orders, we deem it necessary to bring back the concept of "recidivist" in penal legislation and, accordingly, enhance legal measures against foreign nationals who served a custodial sentence.

Concerning the Boundedness of Solutions of a First-Order Linear Implicit Volterra-Stieltjes Integro-Differential Equation

Samandar Iskandarov, Abdibait M. Baigesekov, Zhoro O. Tolubaev, and Gapar A. Dyikanov

Abstract Sufficient conditions like a sign of functions of boundedness of solutions of a first-order linear implicit Volterra-Stieltjes integro-differential equation on the semiaxis if the derivative of the increasing function in which integration is performed, may have discontinuities in certain points of the semiaxis. The method of rearrangement of equations, the method of weight functions and cutoff functions, and the method of integration by parts are explicated. An illustrative example is made.

Keywords Volterra-Stieltjes integro-differential equation · Derivative of the increasing function · Boundedness · Weight function · Cutoff function

All functions presented below and their derivatives are continuous and the ratios are valid at $t \geq t_0$, $t \geq \tau \geq t_0$; $J = [t_0, \infty)$; VSIDE is the Volterra-Stieltjes integro-differential equation; $g(t)$ is the increasing function in J; conditions like a sign of functions shall be regarded as the following conditions using signs $>, \geq, \leq$.

Problem To establish sufficient conditions like a sign of boundedness functions on perpetual half-interval J of all solutions of a first-order linear implicit VSIDE of type

$$x'(t) + a(t)x(t) + \int_{t_0}^{t} K(t,\tau)\, x'(\tau)\, dg(\tau) = f(t), \quad t \geq t_0 \tag{1}$$

if function $g'(t)$ can have points of discontinuity of the second kind [1, p. 220] in some points of the half-interval J, where $dg(t)$ is understood in the sense of definition given by Asanov [2].

As far as we know, this problem has never been studied before. In order to solve this problem, we shall explicate the method of rearrangement of Volterra equations [3, pp. 194-217], and the method of weight functions and cutoff functions [4]; in addition, the traditional method of integration by parts has been increasingly developing and largely used similar to Article [5].

We shall now proceed with achieving the main result.

Let us assume that [4]: $0 < \varphi(t)$ is a certain weight function,

$$K(t,\tau) = \sum_{i=1}^{n} K_i(t,\tau), \qquad (K)$$

$$f(t) = \sum_{i=1}^{n} f_i(t), \qquad (f)$$

$\psi_i(t)$ $(i = 1 \ldots n)$-certain cutoff functions,

$$R_i(t,\tau) \equiv \varphi(t)\, K_i(t,\tau)\, (\psi_i(t)\, \psi_i(\tau))^{-1},$$
$$E_i(t) \equiv \varphi(t)\, f_i(t)\, (\psi_i(t))^{-1}$$

$(i = 1 \ldots n)$; $c_i(t)$ $(i = 1 \ldots n)$—certain functions.

In a similar way to [6, p. 25] we shall say that condition (R) is met if:

I. $R_i(t,t_0) \geq 0$, $R'_{ig(t)}(t,t_0) \leq 0$, there are such functions $c_i(t)$ that $(E_i(t))^2 \leq R_i(t,t_0)c_i(t)$, $\left(E'_{ig(t)}(t)\right)^2 \leq R'_{ig(t)}(t,t_0)c'_{ig(t)}(t)$ $(i = 1 \ldots n)$;

II. $R'_{ig(\tau)}(t,\tau) \geq 0$, $R''_{ig(t)g(\tau)}(t,\tau) \leq 0$ $(i = 1 \ldots n)$.

We shall note that derivative of the increasing function $g(t)$, as well as partial derivatives $R'_{ig(t)}(t,t_0)$, $R'_{ig(\tau)}(t,\tau)$, $R''_{ig(t)g(\tau)}(t,\tau)$ of function $R(t,\tau)$ are regarded in the sense of definitions from [2], such as:

$$\lim_{\Delta t \to 0} \frac{b(t+\Delta t) - b(t)}{g(t+\Delta t) - g(t)} = b'_{g(t)}$$

is the derivative of function $b(t)$ in $g(t)$;

$$R'_{ig(t)}(t,\tau) = \lim_{\Delta t \to 0} \frac{R_i(t+\Delta t,\tau) - R_i(t,\tau)}{g(t+\Delta t) - g(t)} \quad (i = 1 \ldots n)$$

(if there is a limit),

$$R'_{ig(\tau)}(t,\tau) = \lim_{\Delta\tau\to 0} \frac{R_i(t,\tau+\Delta\tau) - R_i(t,\tau)}{g(\tau+\Delta\tau) - g(\tau)} \quad (i = 1\ldots n)$$

(if there is a limit),

$$R''_{ig(t)g(\tau)}(t,\tau) = \frac{\partial R_{ig(t)}(t,\tau)}{\partial g(\tau)},$$
$$R''_{ig(\tau)g(t)}(t,\tau) = \frac{\partial R_{ig(\tau)}(t,\tau)}{\partial g(t)} \quad (i = 1\ldots n);$$

in addition, it is assumed, that

$$R''_{ig(t)g(\tau)}(t,\tau) = R''_{ig(\tau)g(t)}(t,\tau) \quad (i = 1\ldots n).$$

We shall note that if we denote $\frac{dx(t)}{dg(t)} \equiv x'_{g(t)}$, then [7, p. 50]:

$$x'(t) = \frac{dx(t)}{dt}\frac{dg(t)}{dg(t)} = \frac{dx(t)}{dg(t)}\frac{dg(t)}{dt} = g'(t)\,x'_g(t). \tag{2}$$

With provision for ratio (2) and integration by parts, in a similar way to [6, p. 40; 7, p. 51] we obtain the following:

$$\begin{aligned}
&\int_{t_0}^{t} a(s)\,x(s)\,\varphi(s)x'(s)dg(s)\\
&= \int_{t_0}^{t} a(s)\,\varphi(s)\,g'(s)x(s)\,x'_g(s)dg(s)\\
&= \frac{1}{2}\int_{t_0}^{t} a(s)\,\varphi(s)\,g'(s)d_g(x(s))^2\\
&= \frac{1}{2}a(t)\varphi(t)g'(t)\,(x(t))^2\\
&\quad - \frac{1}{2}a(t_0)\,\varphi(t_0)g'(t_0)\,(x(t_0))^2\\
&\quad - \frac{1}{2}\int_{t_0}^{t} \left(a(s)\,\varphi(s)\,g'(s)\right)'_g\,(x(s))^2 dg(s).
\end{aligned} \tag{3}$$

where $d_g(x(t))^2 \equiv \frac{d(x(t))^2}{dg(t)}\,dg(t)$ is the differential of function $(x(t))^2$ in function $g(t)$.

In the following, we proceed in a similar way to [5] for the second-order VSIDE.

For any solution of $x(t)$ we shall multiply VSIDE (1) by $\varphi(t)\,x'(t)$ [8], integrating in increasing function $g(t)$ within the range from t_0 to t, including by parts; concurrently, we introduce conditions $(K), (f)$, functions $\psi_i(t)$, $R_i(t,\tau)$, $E_i(t)$, $c_i(t)$ $(i = 1 \ldots n)$ [4, 9] and apply lemma 1.2.1 [6, pp. 21–23]. Then, with provision for ratio (3) we shall obtain the following identical equation:

$$
\begin{aligned}
&2\int_{t_0}^{t} \varphi(s)\,(x(s))^2\,dg(s) + a\,(t)\,\varphi(t)g'(t)\,(x(t))^2 \\
&-\int_{t_0}^{t} \left(a\,(s)\,\varphi(s)\,g'(s)\right)'_g\,(x(s))^2\,dg(s) \\
&+\sum_{i=1}^{n}\Big\{R_i(t,t_0)(X_i(t,t_0))^2 - 2E_i(t)X_i(t,t_0) + c_i(t) \\
&-\int_{t_0}^{t}\left[R'_{ig(s)}(s,t_0)\;(X_i(s,t_0))^2 - 2E'_{ig(s)}(s)X_i(s,t_0) + c'_{ig(s)}(s)\right]dg(s) \\
&+\int_{t_0}^{t} R'_{ig(\tau)}(t,\tau)\,(X_i(t,\tau))^2 dg(\tau) \\
&-\int_{t_0}^{t}\int_{t_0}^{s} R''_{ig(s)g(\tau)}(s,\tau)\,(X_i(s,\tau))^2\,dg(\tau)\,dg(s)\Big\} \equiv c_*,
\end{aligned}
\tag{4}
$$

where $X_i(t,\tau) \equiv \int_{\tau}^{t} \psi_i(\eta)\,x'(\eta)\,dg(\eta)$ $(i = 1 \ldots n)$,

$$
c_* = a\,(t_0)\,\varphi\,(t_0)\,g'(t_0)\,(x(t_0))^2 + \sum_{i=1}^{n} c_i\,(t_0).
$$

Theorem *Let us assume that (1) $g(t)$ is the increasing function, $\varphi(t) \geq 0$; conditions of $(K), (f), (R)$ are met; (2) $a\,(t)\,\varphi(t)g'(t) \geq 0$, $\left(a\,(t)\,\varphi(t)g'(t)\right)'_g \leq 0$.*

Then, for any solution of $x\,(t) \in C^1(J, R)$ with any initial data $x\,(t_0)$ the following assertions are valid:

$$
\int_{t_0}^{t} \varphi\,(s)\,\left(x'(s)\right)^2 dg(s) \;\leq\; c_*, \tag{5}
$$

$$a\,(t)\,\varphi(t)g'(t)\,(x(t))^2 \le c_*. \tag{6}$$

In accordance with conditions of the theorem, the correctness of conclusions (5) and (6) follows from identical Eq. (4). Yet we shall note that due to I) from condition (R), the fulfillment of the following inequality is achieved:

$$R_i(t,t_0)\,(X_i(t,t_0))^2 - 2E_i(t)X_i(t,t_0) + c_i(t) \ge 0,$$
$$R'_{ig(t)}(t,t_0)(X_i(t,t_0))^2 - 2E'_{ig(t)}(t)X_i(t,t_0) + c'_{ig(t)}(t) \le 0 \quad (i = 1\ldots n).$$

The theorem suggests the

Conclusion
If all conditions of the theorem are met and $a\,(t)\,\varphi(t)\,g'(t) \ge a_0 > 0$, $(x\,(t))^2 \le a_0^{-1}\,c_*$, i.e. any solution $x(t) \in C^1(J,R)$ with any initial data $x(t_0)$ is constrained by J.

We shall give a simplest

Example For VSIDE

$$x'(t) + \frac{t+2}{t+1}\,x(t) + \int_0^t \frac{e^{t\,(\sin t)^{1/3}+\tau\,(\sin\tau)^{1/3}}\,\sqrt{\tau}\,(t+1)^2(\tau+1)^2}{\sqrt{t}-\sqrt{\tau}+5}x'(\tau)\,d\sqrt{\tau}$$
$$= -\frac{e^{t(\sin t)^{1/3}}(t+1)^2}{\sqrt{t}+6}, \quad t \ge 0$$

all conditions of the theorem and conclusion are met at $\varphi(t) \equiv \sqrt{t}$, here $t_0 = 0$, $g(t) \equiv \sqrt{t}$, $\varphi(t)g'(t) \equiv \frac{1}{2}$, $a(t)\,\varphi(t)\,g'(t) \equiv \frac{t+2}{2(t+1)} \ge \frac{1}{2}$, $n = 1$, $\psi_1(t) \equiv \sqrt{t}(t+1)^2 e^{t\,(\sin t)^{1/3}}$, $R_1(t,\tau) \equiv \frac{1}{\sqrt{t}-\sqrt{\tau}+5}$, $E_1(t) = -\frac{1}{\sqrt{t}+5}$,

$$c_1(t) \equiv \frac{1}{\sqrt{t}+5}.$$

In this example $g'(t) = \frac{1}{2\sqrt{t}}$, has a point of discontinuity of the second kind $t = 0$. However, $\varphi(t)\ g'(t) \equiv \frac{1}{2}$. This is what the introduction of weight function $\varphi(t) \equiv \sqrt{t}$. can be justified by.

As can be seen from the above, it has been demonstrated that the above-formulated problem is solvable.

Comment
Using the similar method that was explicated for VSIDE (1), we can examine the boundedness of solutions of a first-order weakly nonlinear implicit VSIDE on half-interval J of the following type:

$$x'(t) + a(t)x(t) + \int_{t_0}^{t} K(t,\tau)\, x'(\tau)\, dg(\tau) = f(t)$$

$$+ F\left(t, x(t), x'(t), \int_{t_0}^{t} H\big(t, \tau, x(\tau), x'(\tau) dq(\tau)\big)\right), \quad t \geq t_0 \tag{7}$$

where functions $F(t, x, y, z)$, $H(t, \tau, x, y)$ are continuous at $t \geq t_0$, $t \geq \tau \geq t_0$, $|x|, |y|, |z| < \infty$ and meet the conditions of "weak nonlinearity":

$$|F(t, x, y, z)| \leq f_0(t) + g_0(t)|x| + g_1(t)|y| + g_2(t)|z|, \qquad (F)$$

$$|H(t, \tau, x, y)| \leq h_0(t, \tau)|x| + h_1(t, \tau)|y| \qquad (H)$$

with non-negative $f_0(t)$, $g_k(t)$, $h_j(t, \tau)$ $(k = 0, 1, 2;\ j = 0, 1)$; $q(t)$ is the increasing function. In this situation, lemmas 1.2.1, 1.2.2 [6, pp. 21–23] are used and the method of integral inequalities is explicated with the use of lemma 1.2.3 [6, p. 23, 10] and the Cauchy–Bunyakovsky–Schwarz inequality is also used if functions $G_1(t, \tau) \equiv g_2(t)\, h_1(t, \tau)$ and $\varphi(t)$ have common zeros.

Geodigital Interests of Russia in the Twenty-First Century

Alexey V. Savchenko, Sergey A. Antonov, and Mariya Yu. Katalkina

Abstract The paper presents an analysis of geopolitical interests of Russia in respect of the conditions of digital economy development throughout the world and identifies the measures for maintenance of national security at the level of state policy, which include: (1) The theoretical and methodological block that proposes the introduction into the scientific circulation of the new concept of "geo-digital interests", which allows to define them in relation to the strategy of public administration in Russia. The authors proposed the basic principles for identifying Russian geo-digital interests, and also considered measures to correct the development strategy of the Russian digital economy in terms of supporting the domestic digital industry based on a synthesis of foreign experience and their own scientific, technical and strategic developments. (2) The organizational and economic block, within the framework of which it's recommended to provide in state programs of socio-economic development of Russia targeted funding for the training of digital consultants, aimed at improving the innovativeness and efficiency of managerial, supporting and production processes in organizations, through the targeted implementation of digital tools. One of the original solutions proposed by the authors to increase the competitiveness of Russian industrial enterprises is the organization of "living offices", units that rely on the effectiveness of their activities on human potential. (3) Support for positive social and creative trends emerging in Russia in recent years, which include increased investment in the educational and technological areas, stimulation of publication and patent activity, and support for the Russian socio-cultural space. One of the main results of the work is the scientific position that in order to protect Russia's geo-digital interests during the transformation of the global economy, financial assistance at the level of state programs is necessary for the socio-economic development

1 Introduction

Modern international challenges necessitate an adequate conceptual and theoretical underpinning. In particular, the peculiarities of geopolitical concepts of confrontations emerging in the digital international economic arena, necessitate the improvement of terminology describing these concepts, while the scientific hypothesis for the content and the structure of geopolitical interests of Russia in the digital economy requires comprehensive discussion among politicians, academic researchers and experts of the digital sector.

The concept proposed by the authors—geo-digital interests is a reflection of the geopolitical interests of the state in the international space of the digital economy. Geodigital interests of Russia (hereinafter referred to as GDIR) as the type of geopolitical interests related to the position of the state in the digital economy, are increasingly becoming one of the key factors of national security in the twenty-first century, and the definition and development of strategic measures to protect these interests appears to be a critical task in the era of digital wars both at the microlevel and microlevel. Our research is aimed at developing measures aimed at strengthening competitiveness and efficiency of Russian companies through the use of digital solutions with a view to maintaining national security of Russia.

It seems to us that development of human potential that is strongly supported by several state-run projects and programs is the main factor that determines the performance of project measures. For example, Federal Project "Personnel for the Digital Economy" or "The Program of Promotion of Scientific, Scientific-Technical and Innovative Activities". We should also mention the initiatives of private companies (in particular, Google's "20% of time" strategy, which gave rise to the emergence of such services as Gmail, Google Maps, Google News and also scientific exhibitions for personnel held by Microsoft, etc.). On the other hand, in the context of the modern COVID-19 pandemic, we are witnessing the using of digital technologies in order to limit and control the movement of the population, which creates a contradictory perception of their focus on improving the quality of life.

2 Background and Methodology

The currently existing geopolicy theory combines global processes occurring in the modern world using the concept of domination in civilizational development based on economic and military potential. In particular, the United States are constantly attempting to demonstrate the application of this concept in their policy.

On the other hand, geopolitical theory distinguishes the following aspects as strategic cause success factors: geographical position, size of territory and population, climate, natural resources and mineral deposits, scientific and educational potential, etc. Geopolitical theory is primarily aimed at ensuring the possibility to explain the world processes of delimitation and redistribution of areas of influence between the leading states across the globe, geographic position of which determines economic factors and creates certain political interests, driving interstate conflicts and transformation of spheres of influence in the modern international political arena. In its development, this theory led to the emergence of many new concepts, such as cold war, color revolution, trade war, demographic war, information and communication war, etc.

Since 1973, after the release of Daniel Bell's book "The Coming of Post-Industrial Society" [1], the term "postindustrialism" permanently established itself in the geopolitical dictionary. Bell believed that postindustrial development is determined by the preponderant position of knowledge, which will lead to "flow production of information", just as industrial revolution and conveyor production have given rise to a mass consumption society. In parallel with post-industrial ideas, the concept of the information society has evolved. These ideas have prompted many authors to develop scientific hypotheses for the domination of information as a geopolitical factor, giving rise to terminological development, and, eventually, theory and practice of distribution of digital goods and services led to the emergence of a new concept—digital economy, hence, the emergence of national geopolitical interests related to the digital economy.

The digital economy, which represents the vast scope of application of relevant technologies, relies heavily on industrial enterprises. The innovative development of it depends on the effectiveness of the interaction of the basic elements. Based on institutional theory, it's through the creation of certain living units that the sustainable development of an industrial enterprise is possible.

At the same time, it must be understood that each enterprise, especially its "living cells" (units) is, first of all, the human potential considered by the authors through the category of human capital, which includes innate (acquired) talents and abilities that can be enhanced by appropriate investments [2].

Human potential is defined as the social quality of the development of potential opportunities of a society or its individual social group [3] and consists of a combination of the physical and moral health of the population, the accumulated amount of professional and general cultural competencies and the civic, entrepreneurial, creative initiative that are manifested in different areas of activity and the structure of needs, both individual and social [4].

Human potential, in its entirety, becomes the basis of living units that ensure the competitiveness of enterprises in the national economy, which in the context of geodigital interests is a factor in Russia's social and economic security in the context of the digital transformation of world systems and processes.

Thus, the main reference materials for the research were Russian and foreign learned treatise, information and analytics from the public mass media, and statistical data of public authorities. The basic methodological techniques of research were the formulation of scientific hypotheses, aggregated analysis of problems, and designing original solutions.

3 Discussion and Results

Digital transformation of society requires the government to have a clear and unambiguous strategy for the development of digital environment, and this requires an understanding (vision) of its geopolitical stance. What we mean is not the marks on the interactive geographic map, but the correlations of power between the national digital economy and digital resources of suspected opponents (allies). Designing a geopolitical map of the global digital economy, just as carrying out a comprehensive comparative analysis of main leaders is a tricky business. Yet we should begin with the introduction of a new concept of geodigital interests into scientific practice. These shall be understood to mean a variety of geopolitical interests that determine a country's political stance in the global digital market. Realizing the controversy surrounding this provision, the authors are aimed at focusing not so much on the identified entity as on the need to define it in the course of discussions in the academic community, the public, and government authorities (identifying a scientific problem). This is because the absence of a term does not render these interests irrelevant.

Thus, the International Telecommunication Union reported that more than half of the world's population [5] had become Internet users by 2018. It took only eight years since 2010 to double the number of subscribers using the Internet. In 2010, the Internet was used by less than 30% of the global population. In the meantime, in addition to the information technology and economic components of such development, the social and political components of trends of development of digital technologies must be taken into consideration as well. So, the picture of the current situation in macrosystems, which is formed by Internet users and viewers, are often too tendentious and divorced from reality, resulting from the "millions of repetitions" of false facts (in fact, a deception) posing a direct threat to public security.

The key points that have been highlighted inevitably leads us to a reflection on the need to develop the Geodigital Strategy of the Russian Federation and to define the respective interests based on the following principles:

1. Reliance on existing geopolitical interests of Russia.
2. Achieving the objectives of the social and economic development of Russia.
3. Strengthening political stability and traditional Russian moral values.

4. Guaranteeing security of Russian citizens, organizations, and the Russian Federation in general.
5. Human development in Russia.
6. Consistent transformation of Russian conceptual creative and inventive opportunities into improved competitiveness of domestic sectors and companies.
7. Introduction of Artificial Intelligence technologies.
8. Guaranteeing the achievement of one of the leading positions in the global digital economy by Russia.

It is necessary to understand the structure and content of GDIR for the improvement of development of the digital economy of the Russian Federation and, consequently, foreign economic policy, the concept of economic security and similar aspects of the government of the Russian state. It seems to us that the GDIR should be based on the development of the domestic digital industry and it also should stimulate an increase in the fruitfulness of scientific and technical developments of Russian scientists and specialists.

The policy documents of the state under consideration, in particular: The Decree of the President of the Russian Federation No. 203 "On the Strategy for the Development of the Information Society in the Russian Federation for 2017–2030" of May 5, 2017 [6]; the Government Program "Digital Economy of the Russian Federation" [7]; the Decree of the President of the Russian Federation No. 490 of 10.10.2019 "On the Development of Artificial Intelligence in the Russian Federation" [8] remain the subject of national conversation. However, it seems to use that a common shortcoming of the Russian digital strategy is the lack of a preliminary definition of domestic geodigital interests as a basis for choosing priorities for the development of the national strategy in the digital field, and lack of attention to measures aimed at developing and unlocking the potential of Russia in the innovation sector.

As has already been noted, the exceptional strengthening of military and political power in the era of informatization and globalization does not provide a reliable protection of economic interests of the state. For this reason, the authors consider it necessary to focus the national state-run programs of support of social and economic development on the production of domestic digital products and services, developed with reliance on Russian scientific-technical reserves, and if there are no such reserves, share the work results of partners from the CIS countries and foreign know-how.

The data from Strategic Partners (hereinafter referred to as SP) show that as little as 17% relatively large enterprises are involved in pilot digital projects according to the roadmap. And this is not due to the failure to grasp the importance of this area, since almost half of Russian industrial companies (48%) agree about the topicality of the issue, but rather the lack of organizational forms and professionals who would be able to carry out digital transformation aimed at organizational development. This being said, there is another opinion, according to which 17% companies do not consider these projects as top-priority at all [9].

One way or another, the using of information technology today is an urgent task, but the question remains: to what extent will it be really useful to an industrial enterprise. As noted in the article earlier, on the one hand, information services facilitate the work, and on the other, create some kind of barrier between the leader and the real processes. Lack of knowledge of the features of modern goods and services existing on the digital market of Russia and conditional understanding of the capabilities of certain software solutions, their advantages and disadvantages, technological characteristics, put enterprise managers in a situation of intuitive choice, which reduces the quality of labor results and increases unproductive expenses.

It is obvious that implementation of this service requires involvement of specially trained professionals—digital consultants, who, on the one hand, should be competent in the existing hardware and software, their price and functional characteristics, while on the other hand, understand the peculiarities of the productive-economic and organizational-management activity of a particular company. Under the circumstances, we believe it would be reasonable to create a service of digital consulting as an activity aimed at enhancement of efficiency of all main groups of processes in the organization: basic (production, operation), supporting (commercial, economic) and management (organizational, innovative) due to existing digital solutions in the market. The same service could assist in the development of the terms of reference as well as in the implementation of a digital solution.

Public authorities have already begun work in this direction. So, by order of the Ministry of Labor of the Russian Federation on October 31, 2018, a new professional standard was approved "Digital Literacy Development Advisor (Digital Mentor)" was approved pursuant to the Order of the Minister of labor and social protection of the Russian Federation No. 682N of 31.10.2018 [10]. However, this profession deals with counseling the population, which doesn't solve the problems of innovative development of industrial enterprises in Russia and local authorities.

It's noteworthy that among the organizations involved in the digital transformation process, Russian state higher education institutions are in the forefront. According to the Federal State Statistics Service (Rosstat), in 2017, it is they that were ranked first among organizations using electronic document management (77.6%) [11]; however, as noted by the Special Representative of the President of the Russian Federation for the digital and technological development Dmitry Peskov, "emergence of a software program which is used for keeping accounting records, making the electronic timetable, and conducting online courses—all of this is not a digital university. The main thing is how teaching and learning activities are conducted, how they influence the quality of the educational outcome" [12]. It seems that in a similar way the question should be raised in terms of improving the efficiency of operational activities and enterprise management, i.e., clearly see the purpose of the software and hardware solution and the expected result (saving resources, improving the quality of work).

Despite the fact that today there are consulting services in the area of digital transformation of business and public authorities; however, the cost of these services in the market is quite high. In particular, a one-time, three-hour consultation on a project in the Digital Economy Development Fund for the Digital Economy costs

99 thousand rubles for business, and assistance in preparing digital transformation plans for government agencies costs 499 thousand rubles [13].

In addition, the effectiveness of consulting in the area of information technology is limited by the following circumstance: a consultant can continuously deepen his knowledge in the area of digital technologies, and only a few have the ability to immerse themselves in the characteristic features and problems of a particular enterprise. Therefore, most often, consulting comes down to improving the enterprise on the basis of standard solutions of a consulting agency, which is expensive and relatively effective for the customer.

In this regard, the authors propose to organize a living office at each medium and large industrial enterprise a special development institute, which would ensure the full-time employment of consultants-specialists in the operational and tactical development of the enterprise, including in the field of information technology.

The formation of a special atmosphere for this category of specialists in a living office is designed to contribute to a deep insight into the processes taking place in the external and internal environment of the enterprise, and also to develop solutions for its development, taking into account the need and sufficiency of digital tools.

If a specialist consultant can be a full-time unit in the headquarters staff of the managerial office in small enterprises, then an organizational unit (department, unit) is required in medium and large enterprises. Using the adjective "living", we emphasize the need to rely on the formation and implementation of national human potential in the interests of the innovative development of industrial enterprises in Russia.

Thus, Norway (0.95) has been the leading country in the Human Development Index for quite a while already, and Russia is ranked 49th with a score of 0.816, which is above the average world-wide value of this indicator (0.728). It is comforting to realize that by this indicator we belong to the leaders of the world ranking. It seems to use that the results of the Global Innovation Index [14] are interesting from the perspective of assessment of human potential. So, in 2019, Russia preserved its 46th position in the overall ranking, including due to its high rating with respect to the parameter "Human Capital and Scientific Research" (23rd position). In addition, the following items are noteworthy:

- high rating in terms of the number of patent applications for a discovery—20th position;
- 33rd position in terms of research and development expenditure;
- 45th position in terms of the use of information and communication technologies;
- a fairly low rating—72nd position on the whole block "Results of creative work", including
- intangible assets—71st position;
- creative goods and services—88th position;
- as well as the 47th position in terms of online activity parameter (mobile application development, generic and country code top-level domains, etc.) which stands out from the others.

All of the outcomes listed above resulted in a significant gap between innovation inputs and innovation outcomes (41 as compared to 59).

In accordance with the information published on the Rosstat website for 2018 [15], the scientific and creative potential and its results can be characterized as follows:

- the number of students—16,173,300 people;
- the number of graduated bachelors, specialists, magisters—933,200 people;
- the number of organizations that carried out research activities—3,950 (there is an overall increase by 0.02%, yet the number of design organizations has decreased by 7%, and the number of pilot-producing plants has decreased by 33%);
- the number of personnel involved in research and development activities (exclusive of auxiliary and other personnel)—405,576 people (a decrease by 4% compared to 2017);
- advanced manufacturing technologies that are being developed—1,565 pcs (an increase by 11.6%);
- advanced manufacturing technologies that are being used—254,927 pcs (an increase by 6%);
- the amount of finance provided to science out of federal budget has been annually increasing in volume terms by 5–10% for the last three years; moreover, this value has been decreasing against GDP for the last six years, and was 0.4 at year-end 2018;
- the percentage of innovative goods, works, and services in the total volume of goods shipped, work performed and services delivered is 6.5% (decreased by 0.7%);
- the number of patent applications submitted and copyright protection documents granted: applications submitted—37,957, patents granted—35,774; moreover, we can observe an interesting trend that has been developing over the last 5 years—the number of patents granted on average increases by 3–5%, while the number of applications submitted decreases by 10–12% annually.

Thus, the share of researchers in the total economically active population of Russia is about 0.5%, which is significantly lower than the share of the entire European Union—0.842 and its individual countries, in particular: Czech Republic—0.761, Germany—0.999, France—1.028 etc. [16]. Of course, it may be noted that there has been a positive trend in the development of human potential over the last several years, yet there are several indicators according to which Russia lags behind developed countries, which necessitates the correction of strategic priorities of Russia (its national programs) towards ensuring high scientific-technical human potential of our country [17–21].

4 Conclusions

The novelty of the study is confirmed by the introduction into scientific circulation:

1. Concepts—geo-digital interests that allow you to take a fresh look at the effectiveness of applying the conceptual and theoretical criteria used in the development,

monitoring and correction of the development strategy of the digital economy of Russia.
2. Conceptually determined criteria and principles necessary for determining the geo-digital interests of Russia.
3. Initial provisions for organizing a scientific discussion on the issue of increasing the competitiveness of the development processes of the Russian digital economy, by clarifying Russian geo-digital interests in the national security system of the Russian Federation.

Summing up the main results, we can emphasize the following:

1. The lack of public discussion on Russian geodigital interests does not mean that there are no such interests. On the contrary, as time goes by, the relevance of their definition increases, but is not yet obvious to everyone. As for our opinion, it appears that taking into account the potential modern geopolitical trends, it is necessary to make comprehensive amendments in the national programs aimed at improving support to the domestic digital sector and developing Russian scientific and creative potential.
2. In order to protect national geodigital interests, innovative transformation of Russian organizations should be supported at the level of state-run programs of social and economic development through special-purpose funding of creation of Institutes for Development (digital offices), at the first stage, allocating it to state-owned enterprises, and subsequently supporting the introduction of these institutions in the private sector.
3. It appears to us that ability to generate new ideas, which is reflected in fairly high publishing, patent activity, is a strength of human domestic potential in the digital sector. The weak side is the low efficiency of the dissemination (implementation) of knowledge in the operational and tactical activities of industrial enterprises, and their impact on changing the structure of the country's economy and improving the quality of life of society. As a result of this, the main areas of development could be: increasing investment in education and technological modernization; increasing the priority of social development; creation of mechanisms to identify socio-cultural interests and support for children and youth.

The Use of Mathematical Apparatus Data Envelopment Analysis for the Rating Analysis of Companies in a Digital Economy

Nikolay V. Kuznetsov, Ksenia V. Ekimova, and Elena V. Polyakova

Abstract The paper deals with special aspects of the use of mathematical apparatus Data Envelopment Analysis (DEA) for the analysis of relative performance of activities of companies operating in the digital economy sector. The DEA algorithm was implemented using the MATLAB math package. It was used for the analysis of the 11 major companies from the United States, China and Russia operating in three different sectors: production and delivery of equipment and facilities, provision of telecommunication services, and provision of various digital services. The performance of companies was assessed from the perspective of their ability to use the resources at their disposal to generate profit and cash flow for shareholders (i.e., profit and cash flow per share). It has been demonstrated that currently companies providing various digital services and facilities demonstrate the highest performance. The second position in terms of performance, far behind from the leaders, is held by telecommunication carriers. The lowest efficiency is demonstrated by companies whose activities are focused on the manufacture of equipment and facilities. This fact may be attributable to the high costs of research, development and production modernization emerging from the need to update the product line on a continuous basis. The dividend yield of company shares has been analyzed versus their market-value appraisal. The most attractive companies in terms of investment attractiveness have been identified. It has been established that the performance of English companies fully corresponds to their foreign competitors, despite the much smaller range of activity, capitalization and market-evaluation value. This makes them sufficiently attractive investment projects in the medium and long term. The strengths and shortcomings of this approach have been analyzed. It has been concluded that simplicity

1 Introduction

The digitalization of the economy and public life gave rise to emergence and development of digital companies. While some of them are traditional manufacturers producing digital equipment or infrastructure elements, others focus on the provision of digital services and services. High speed of ingression of modern technologies into all fields of activities of society, in turn, determines also the high rate of development of these companies. Thus, the top 20 positions in the rating of fast-growing high-technology companies, prepared by Deloitte in 2018, were held exactly by companies from the digital sector. Their average growth rate for the period from 2014 till 2017 was 969% [8], which is significantly higher than the growth rate of even those companies that deal with basic materials.

Such growth promotes the formation of own ecosystems around digital companies consisting of enterprises and facilities providing services to these digital companies, ensuring new job formation and development at a regional scale [14]. Some of these systems eventually turn into giant clusters which become the face of the national economy. Thus, in the assessment of the economic achievements of Finland, scholars from Helsinghin Teknillinen Yliopisto attribute 50% of the country's GDP growth to the extraordinary success of Nokia Corporation, which managed to achieve almost a five-fold increase in revenue over the years of its prosperity [1]. Even after the decline of Nokia, 23 other companies related thereto continued to increase their sales volumes, which allowed Finland to fairly successfully withstand the world recession [10].

It is fair to say in this day and age the mere development of companies in a digital economy can provide the rapid economic development of the country in the global space, when a certain national economy grows at a rate that exceeds the overall growth rate of the international economy [15]. That said, according to the analysis, this growth turns out to be little dependent on the world market conjuncture [17].

All of the above accounts for the focused attention to such companies by analysts working for both public and private institutions.

However, when researching companies in a digital economy, the analysts far too often face significant lack of information. On the one hand, this is due to the

strict non-disclosure regime in effect in such companies—to ensure their competitiveness digital companies often conceal not only their current advanced development and strategic plans, but also existing internal business processes, management system, operating decision-making rules and logic, etc., and on the other hand—high dynamics of activity, when information published in public sources after a very short period of time turns out to be irrelevant as a result of changes [12]. Thus, analysis is often carried out in a situation when public sources provide only most general and highly limited information on the resources consumed by the company (material, human, financial, time etc.) and the results it produces (material or financial), but information on the internal business environment is virtually lacking or is extremely inconsistent at that.

It is apparent that in the present context standard methods of financial and economic analysis and auditing are ineffective [9]. This poses a challenge to search for new approaches to the analysis of activities of companies operating in the digital economy sector.

2 Methodology

The comparison of company under consideration with similar companies according to several known criteria is one of possible approaches that can be used by an analyst in the context of scanty information. That is, in point of fact, the assessment of performance of a company as compared to the activities of its competitors.

One of the methods of analysis which allows receiving the assessment of relative performance economic systems in the context of information shortage is the "DEA" (Data Envelopment Analysis). This method was first discussed in the late 1970s and early 1980s in the works of Charnes et al. [5], and Banker et al. [2]. Originally designed for comparison of complex engineering systems, it has thus far proved to be useful for economic, social, political and other systems.

At present, the DEA methodology covers much wider range of issues than a mere comparison of efficiency of complex objects. Its mathematical apparatus has been most fully and fundamentally described in the works of such scholars as Cooper et al. [6] and Ray [16]. Nevertheless, in this work, we will examine it in the simplest basic setting.

The DEA approach allows assessing the efficiency of objects under study relative to each other. In addition to the above, every object is treated as a "black box", which transforms input parameters (X) into output parameters (Y) in accordance with the unknown function (f). In respect of economic entities (companies) this can be formulated as follows—"a company consumes a certain amount of resources and converts them into its performance results in a manner unknown to us" (see Fig. 1).

Suppose we have Q companies operating in a competitive environment, each of which is characterized by a set of n input parameters that characterize the resources consumed by the company $(X_1, \ldots X_n)$ and m output parameters that characterize the performance result generated by the company $(Y_1, \ldots Y_m)$. We shall assume that

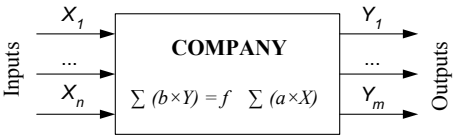

Fig. 1 DEA representation of the economic system (compiled by the authors)

outputs (Y) and inputs (X) are in some unknown way related to each other. Then the ratio of the total weight of the entire result (sum of outputs) to the total weight of all resources consumed (sum of inputs) will be the characteristic of performance of an object (characteristic of performance of the transformation of inputs into outputs). This statement may be written as follows:

$$\theta = \frac{b_1 Y_1 + b_2 Y_2 + \cdots + b_m Y_m}{a_1 X_1 + a_2 X_2 + \cdots + a_n X_n} = \frac{\sum_{i=1}^{m} b_i Y_i}{\sum_{j=1}^{n} a_j X_j}$$

where a and b are weighting factors for input and output parameters respectively.

The simplest economic counterpart of this equation is the profitability index which is calculated as the ratio of ultimate outcome to costs. In this case, performance of a company depends on how much profit it can generate at minimum cost. However, when the DEA method is used, we obtain a multifactorial and non-dimensional indicator (it should be pointed out that the DEA method avoids the need to bring all indicators to the same units of measurement). Another economic counterpart of the DEA approach is the production function, which represents the quantitative ratio between production output values (result or outputs) and factors of production (costs or inputs).

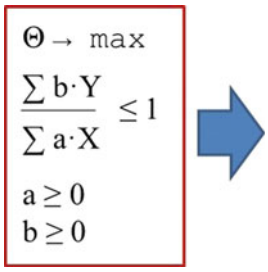
Then the relative efficiency of each company in the set Q can be determined by solving the linear programming problem (shall be solved for the entire set of objects simultaneously):

$$\theta \rightarrow \max$$

$$\begin{cases} bY/aX \leq 1 \\ a \geq 0 \\ b \geq 0 \end{cases}$$

The solution is searched under the condition that the overall maximum is achieved provided that efficiency of each object is ≤ 1 and coefficients a and b cannot be below zero. That said, the following solving algorithm is used [7]:

- one company is selected from the set Q, and such values of weighting factors a and b are picked for it at which performance indicator Θ will have the maximum value;



```
clear all;
% initial values
X = [ ]; % Outputs
Y = [ ]; % Inputs
% Calculatio
[n,m] = size (X);
[n,s] = size (Y);
Z = zeros (n,n+m+s);
f = [zeros(1,n)- ones(1,s+m)]          % Target function
lboutput = zeros(s,1);                 %The lower bound for outputs
lbinput = zeros(m.1);                  % The lower bound for inputs
lb = (lboutput; lbinput);
for j = 1:n
Aeq = [Y', -eye(s,s), zeros(s,m); -X', zeros(m,s),-eye(m,m); ones(1,n), zeros(1,s+m)]
Beq=[Y(j,:)'; -(X(j,:)';1];
Z=linprog(f,[ ],[ ],Aeq,beq,lb);
Z(j,:)=z;
end
Z
```

Fig. 2 Implementation of the DEA model using the MATLAB math package (compiled by the authors)

- the values found *a* and *b* are assigned to all other companies from the set *Q* and their performance indicators *Θ* are calculated and compared with those of the selected company;
- if the selected company seems to be just as attractive as any other companies from the set, its performance is assessed as maximum;
- if any other company from the set seems to be much better than the company that was initially selected, its performance is assessed as below maximum.

Thus, the DEA model allows identifying the most efficient (best) object of the set and comparing all other objects with it. As a result, all companies in the set *Q* are ranked in the range of 0–1 (where rank = 1 for the most efficient company).

The algorithm presented above was implemented using the MATLAB math package. Figure shows a fragment of solution of the DEA model (See Fig. 2).

3 Findings

In order to give an example of practical application of the DEA model, we shall rank several largest foreign and Russian companies in a digital economy (see Table 1). The data are taken from the public financial statements of companies for 2019. The value of assets (TA—Total Assets) and liabilities (TL—Total Liabilities) of the companies were taken as input parameters, and the revenue (R/S—Revenue/Share) and cash flow (CF/S—Cash Flow/Share) per share taken as the output parameter. As can be seen from the above, we will assess the performance of companies judging from their ability to use the resources at their disposal to generate profit and cash flow for shareholders. The financial indicators of Russian companies were brought to the

Table 1 Financial performance of the leading companies in a digital economy (in million USD except shares)

Company	Ticker	Country	TA	TL	R/S	CF/S
Apple	AAPL	United States	338,516	248,028	58.58	15.21
Amazon	AMZN	United States	225,248	163,188	557.14	66.32
Google	GOOG	United States	275,909	74,467	231.70	65.84
IBM	IBM	United States	152,186	131,345	86.41	17.53
IT&T	T	United States	551,951	367,730	24.66	5.88
Alibaba	BABA	China	170,193	80,617	10.11	24.18
Cisco	CSCO	United States	92,492	58,069	11.90	3.15
Xiaomi	1810	China	24,686	12,953	8.95	0.57
MTS	MTSS	Russia	14,797	13,742	4.61	1.55
Beeline	VEON	Russia	14,102	10,432	5.06	1.55
Yandex	YNDX	Russia	4174	1284	7.59	1.44

Compiled by the authors according to figures from Bloomberg [3]

single monetary base at the exchange rate of 61.9057 RUR/USD (fixed by the Central Bank of the Russian Federation on 31.12.2019 [4]).

From the analysis of financial statements one can see that Russian companies generally are greatly inferior to their foreign competitors in terms of scale. Thus, the asset value of the largest Russian mobile carrier, MTS, is 37 times lower than that of the American operator, AT&T, and the asset value of the Russian search engine, Yandex is 66 times lower than that of Google. Moreover, their relative performance cannot be clearly assessed from their financial statements.

The results of calculation of the relative performance rating obtained through the use of suggested approaches are shown in Fig. 3.

Three categories of companies can be clearly identified in the block diagram. "Stars"—companies that are characterized by the maximum performance under current conditions (Amazon, Google, Yandex). The "average performers"—companies whose performance is almost twice as low as the leaders' performance (Alibaba, Beeline, MTS, AT&T, IBM)—follow far behind them. And "underperformers"—companies whose performance is lower than the leaders' performance by 6–8 times (Xiaomi, Apple, Cisco).

Moreover, if we analyze the companies in relation to certain kinds of their activity in the digital economy sector, three clusters can be distinguished here as well.

Cluster 1—"Digital Services", is represented by Amazon, Google, Yandex and Alibaba. It is the companies of this cluster that demonstrate the highest performance today. Moreover, it should be noted that despite much smaller range of activity and capitalization, the current performance of Yandex is in fact on a par with that of Google. At the same time, Alibaba, a Chinese company focused on the development of the electronic trading platform Aliexpress, is not only far inferior to its US competitor Amazon, but also demonstrated the smallest performance among all the

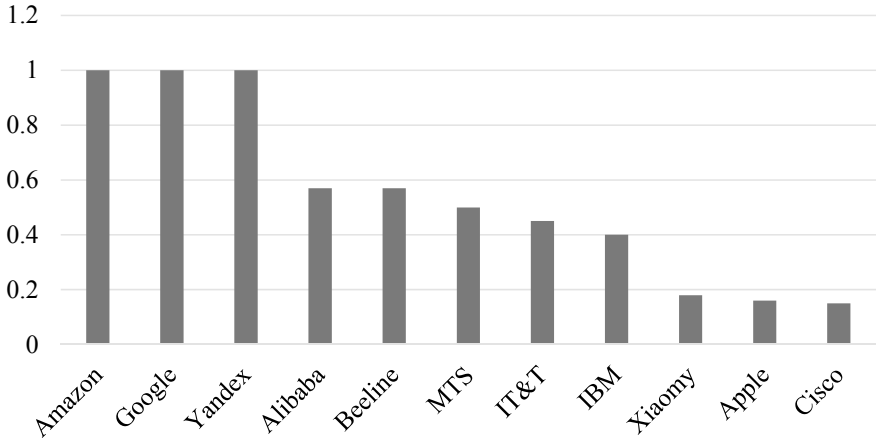


Fig. 3 Relative performance rating of companies in a digital economy (calculated by the authors)

companies in the cluster in 2019. This may have partly been caused by the reciprocal claims between the United States and China in 2019 which threatened to escalate into a full-scale "trade war".

It is also important to note that the companies in this cluster pay virtually no dividends to their shareholders; tending to prefer to channel the profit earned into their further development [3].

Cluster 2—"Telecommunications", is represented by Beeline, MTS and AT&T. It may be pointed out that the performance of Russian mobile carriers (Beeline and MTS) is slightly higher than that of the leading American telecommunication carrier AT&T. This can be partly explained by the fact that AT&T had experienced a sharp increase in the number of subscribers a few years earlier and is currently operating in a glutted market [11].

Companies in this sector have consistently paid out handsome dividends (see Table 2) over the last year. This dividend-related behavior is probably due to the need for companies to maintain their investment attractiveness. This fact applies not only to foreign companies, but also to Russian companies, the market-value appraisal of which is currently significantly lower than that of competitors (for example, the

Table 2 Dividend yield of telecommunication carriers (payouts in 2019)

Company	Dividend yield				P/E
	1st quarter (%)	2nd quarter (%)	3rd quarter (%)	4th quarte r(%)	
IT&T	6.50	6.19	5.46	5.32	20.26
Beeline	9.27	–	11.49	–	7.86
MTS	–	–	8.23	8.86	9.89

Compiled by the authors according to figures from Bloomberg [3]

Table 3 Dividend yield of equipment manufacturers (payouts in 2019)

Company	Dividend yield				P/E
	1st quarter (%)	2nd quarter (%)	3rd quarter (%)	4th quarter (%)	
IBM	4.50	4.31	4.78	4.67	14.37
Cisco	2.76	2.61	2.85	3.19	17.98
Apple	1.43	1.47	1.27	1.00	25.4

Compiled by the authors according to figures from Bloomberg [3]

current value of P/E coefficient of Russian telecommunication carriers is 2.0–2.5 times lower than that of US companies).

Cluster 3—"Hardware" is represented by IBM, Xiaomi, Apple and Cisco. IBM is a definite leader in this sector in terms of performance. Moreover, Xiaomi, the Chinese manufacturer of handheld devices, demonstrates higher performance than such a colossus as Apple, which may be primarily explained by high dynamics of development of this company, which has managed over a 10-year period (from 2010 to 2020) to rise from startup to the 4th company in the world in terms of mobile phone sales and is still increasingly growing.

IBM is characterized by significant dividend payout in this cluster. Its dividend yield comes close to the companies from the telecommunications cluster. That said, the current market-value appraisal of IBM is lower than that of other companies from the cluster of equipment manufacturers (see Table 3). In the aggregate, that makes it attractive from the perspective of investment.

In our opinion, the lower performance of equipment manufacturers among the companies in a digital economy under consideration is attributable to the high costs of research, development and production modernization emerging from the need to update the product line on a continuous basis. Thus, direct sales of each new model on the market of handheld devices take place over a short run (1–6 months), then the model either loses ground and becomes an ordinary product whose sales are based on efficient marketing operations rather than on the leading positions of the model itself, or is completely replaced by emerging new products with superior characteristics [12].

When we analyze the performance of Russian companies in a digital economy, it is fair to conclude that they have good potential for their further development. However, under current economic conditions, there is a need to take a set of expansionary actions for the implementation of this potential. In particular, public policy aimed at increasing the availability of financial resources for such companies will have a beneficial effect [13]. Moreover, it is necessary to make sure that this financial backing is mainly directed to the implementation of digital business development programs (advance research, capital expenditure, etc.) and not only to business operations.

4 Conclusion

The rating analysis of companies in a digital economy we have carried out using the mathematical apparatus DEA, has made it possible to discover that currently companies providing various digital services and facilities demonstrate the highest performance. The companies whose activities are focused on telecommunications are the second most efficient, lagging way behind. The lowest efficiency is demonstrated by the companies producing equipment and handheld devices which are burdened with high material and financial costs. It is apparent that this situation is an overall trend.

In addition to the above, the performance of Russian companies, despite economies of scale, is on a par with their foreign competitors. In this regard, a considerable interest of international investors in the evolving sector of the Russian digital economy becomes quite comprehensible. The prospects for further development of Russian digital companies coupled with their low current value make them an attractive object of medium-term and long-term investment.

The DEA method we have used allows us to simply and quickly assess the relative performance of parties to economic relations with minimum information about their functioning. However, it is characterized by two significant shortcomings at that. First, the resulting estimates are relative (comparative). As a matter of fact, it is impossible to achieve the absolute assessment of performance using this method. The DEA method can demonstrate how well the company functions compared to competitors, but not compared to the theoretical maximum. Second, an expert who uses DEA will always face a problem of justifiability of selection of input and output parameters. In this case, the main mathematical and algorithmic advantage of the method is its tolerance to the indicators under consideration and their dimensions—turns into its shortcoming, since it necessitates that the expert present a clear definition of what he/she currently means by "business performance".

Thus, the approach under study is not self-sufficient, yet it can be used as an efficient tool of preliminary analysis or benchmarking. When we have the minimum of available information, it allows for efficient ranking of companies, distinguishing their apparent leaders and outsiders, and identifying the most significant factors influencing the outcome, in order to better select the area for further in-depth study and more precisely formulate the task of subsequent analytical study.

Implementation of Electronic Document Turnover as a Factor of Increasing the Management Effectiveness in the Digital Economy

Elena Yu. Kuzmina, Aigul B. Alibekova, and Irina V. Soklakova

Abstract *Research goals*: This paper studies the possibilities of using the potential of digitization for increasing the effectiveness of a modern organization management. A lot of organizations still use paper carriers of information, which slows down the speed of making of managerial decisions and reduce its effectiveness. The authors consider information and communication technologies that ensure a lot of processes in an organization without usage of a document, allow systematizing information in view of the set tasks, and allow transferring it between the users, tracking its correctness. *Methodology*: The research was performed with the help of the basic economic methods, based on logical description of the components of electronic document turnover and with application of the systemic approach, which ensures the necessary depth of elaboration of the scientific problem. It is offered to use the advantages of electronic document turnover in combinations of various programs for increasing the effectiveness. Advantages and drawbacks of various programs are analyzed. The program *Diadoc*, which fully conforms to the requirements of the studied logistical company, is analyzed. Effectiveness of implementing electronic document turnover for the studied company and its customers is studied, and the indicators of effectiveness before and after implementation of *Diadoc* are compared. *Results*: Scientific and practical significance of the work consist in studying the tendency of influence of digitization on growth of GDP and organization's activities' effectiveness. The authors analyze the advantages of electronic document turnover for a modern organization, determine the effectiveness of its implementation for a specific organization, and perform evaluation of the time requires for transferring the invoice to a customer, dynamics of loss of invoices, satisfaction of customers

1 Introduction

A common problem for most of the regions of the Russian Federation is incomplete implementation of the digitization potential. The main cause of this, according to the authors, is underestimation of the possibilities of digital technologies and their influence on effectiveness, sustainable growth, and potential of development of certain companies and spheres on the whole.

Digitization has a large potential for long-term growth of all spheres of economy [14]. The effect from implementing digital technologies in the main spheres in the Russian Federation could be compared to the federal budget's revenues from the oil & gas sector. However, even in Moscow the use of the basic digital products—e.g., the systems of electronic document turnover—does not exceed 24%, and in regions—8%.

For accelerating the digital transformation of the Russian economy, a program "Digital economy of the Russian Federation" [10] was adopted; in it, the digital economy is considered to be economic activities which key factor is data in the digital form [9]. It is emphasized that data should become a new asset, which is used for new purposes, for implementing new advantages—increase of economic growth and competitiveness of country, improvement of accessibility and quality of services, and development of new opportunities for creation and development of companies [6].

According to the consulting company McKinsey [7], digitization of the Russian economy will ensure 19–34% of GDP growth by 2025; the share of the digital economy might account for 8–10% of GDP. As of now, its share is 3.9%, which 2–3 times lower than in countries that are leaders in this sphere—e.g., the USA, Singapore, and Israel. However, the positive tendency is that the volume of this market in Russia grows. Thus, Russia's GDP grew by 7% in 2011–2015, while the volume of the digital economy grew by 59%. Thus, the contribution of the digital economy in the total growth of GDP constitutes 24%. The leading countries already face stagnation of the rates of this growth.

McKinsey developed a digitization index, according to which the Russian economy is an active participant of digital transformation, by means of active

investments in development of the infrastructure of information and communication technologies.

The main technological trends of development of the digital economy are as follows: digital platforms, public cloud, multi channels, marketing integration, digital doubles, and digital education.

The main sources of growth of Russia's GDP by means of digitization are optimization of the production and logistical operations and increase of labor efficiency [8]. Thus, improvement of the process of information resources management—e.g., digitization of management in the modern business environment—is one of the most important problems. Companies constantly look for various innovative solutions for optimizing the circulation of information. The digital economy ensures a lot of processes in an organization without usage of documents. The process of economy digitization expands constantly and quickly, and that's why modern organizations have to reconsider the very notion of electronic document turnover.

Information resources management is an important component of company management. The result of insufficient effectiveness of this process could become old, incorrect, and incomplete information, which is unfit for use for the managerial purposes.

The larger the company, the more information resources it has, and the more complex their management are; so large companies often have several programs of information management [11].

These programs allow storing information, systematizing it in view of the set tasks, transferring it between users, tracking its correctness, etc. Programs allow for quick transformation of information in the required forms, which are convenient for analysis (various managerial reports). Thus, it is no wonder that demand for such systems grows [2].

Effectiveness of managing a modern organization and its competitiveness depend on the speed of information transfer between departments, timeliness of processing of documents, and reliability of the information component on the whole [12]. Readiness of the management and personnel for implementing changes is also very important.

Thus, most companies see a large potential in application of various programs for managing their information resources. More and more companies pay special attention to this type of resources – as information is the initial point of development and making of managerial decisions at all levels of the hierarchy, and its correctness, topicality, and quality influence further development. Each company wants to choose a high-quality and convenient system for managing the information flows.

As a matter of fact, implementation of the systems of electronic document turnover into the practice of organizations led to transformation of the processes of documents and tasks management. The authors [5, 13] distinguish the following advantages from implementing the systems of electronic document turnover:

- simplicity and transparency of the process of processing and storing of information;

- instantaneous search for necessary data, free transition along the chain of ties between the documents;
- quick access to any documents according to the level of level of user rights;
- possibility of usage in the form of a cloud service;
- business rules for various directions of work with documents;
- integration with chat bots for coordinating documents in smartphone;
- increased speed and quality of provision of services;
- increase of responsibility, possibility to monitor employee's workload, and transparency of business processes.

2 Methodology

For evaluating the effectiveness of management, modern companies use the key indicators of effectiveness—KPI. Each organization has its own system of indicator, and so the process of calculation of these indicators is not automatized. QA managers perform the calculations manually, using data from various programs. That's why there is a necessity for implementing electronic document turnover for authomatization of the calculation of KPI and bonuses for the employees.

Let us consider authomatization of calculation of the indicators by the example of a logistical company (Table 1).

There is a lot of software for electronic document turnover. An overview of the programs for electronic document turnover is shown in Table 2.

A detailed analysis of all pros and cons of various systems led to selection of Diadoc—as it meets the demands of the logistical company.

Reasons for selecting Diadoc:

1. It allows users to work with all existing accounting systems, unifying the company's business processes.
2. Integration with Neogenic (HEO)—the leading program of information resources management in a logistical company. Employees must be able to send document directly from HEO.
3. The legislative guarantee of the legal effect of electronic documents. The principles of work of Diadoc are transparent, are within the legal norms, and do not require paper copies.

For the test period, several large customers, who work with the company on a constant basis, were selected. Negotiations and discussion of the terms of transfer to electronic document turnover were performed. The project group studied the systems in which the customers work, installed Diadoc, and integrated the programs.

The customers were as follows:

1. Customer 1—a machine-building enterprise.
2. Customer 2—the world leader in production of automatized equipment and reactive chemicals for clinical laboratory diagnostics and biomedical scientific research.

Table 1 List of KPI indicators and their calculation for automatization

KPI indicator	Calculation
Customers with overdue accounts receivable	Calculation by the planned date of payment
Sum of overdue accounts receivable	Sum of all invoices. Calculation by the planned date of payment
Orders with overdue terms	Calculation by the difference between the factual and planned dates of execution of the order
Invoices with overdue terms of transfer	Calculation by the planned date of transfer
Invoices with overdue terms of transfer, sum	Sum of all invoices. Calculation by the planned date of transfer
Invoices with overdue term of transfer (%)	Calculation by the planned date of transfer
Contracted orders (%)	Calculation by the planned date of start
Applications from customers (%)	Calculation by the type of document
Timeliness of entering dates for operations of services provision (%)	Calculation by the one who entered (manager entered - the date was entered with a delay)
Correctness of planning of orders (%)	Difference between the plan and factual execution is no more than three days
Absence of errors on connection of mandatory documents to invoices (%)	By the marks of the control group
Surveys performed	Number
Customer's complaints	Calculation by the criteria
Customers' desires (specification for the issues)	Calculation by criteria
Document turnover	Number
Queries	Number
Informing	Number
General impression of the personal manager	Number
Meeting the terms	Number
Fully satisfied customers (%)	Calculation by the number of customers
Satisfaction of customers (average score)	Average score on general evaluation, by customers
Execution of the plan on training hours	Number of hours
Execution of the plan on training hours (%)	%
New customers, number	Customers who work less than six months, calculation by the first date of act
New customers, profit	Customers who work less than six months, calculation by the first date of act
New customers, profit (%)	% of the total number
New new customers (1 date of act), number	By first orders
New new customers (1 date of act), profit	By first orders
New new customers (1 date of act), profit (%)	By first orders

Table 2 Pros and cons of the systems of electronic document turnover [1, 3, 4, 15]

System	Pros	Cons
1C: Document turnover 8	Working with general document turnover and its archive. Possibility to work with documents from various sources. Possibility to expand the functions	No internal e-mail. No creation of tasks for one or several groups. No module for managing the company's projects. Registration from MS Office is not available. No administration function
Diadoc	Electronic signature, convenient and accessible interfaces. Secure storing of documents. Convenient filter for finding documents of any date. Provision of documents in any regulating bodies. Possibility of creation of a hierarchical structure of departments and distribution of resources between them	Integration with selected systems
Directum	Expanded catalog of business solutions. Three types of storages: for operative work, for archive storing, and for storing large data. Convenient reminders	No page form of documents in the part of description of documents and search results; no additional styles in description of documents. Overloaded interface

3. Customer 3—a company that specializes in manufactures of polymer products for plumbing and heat supply.

3 Results

Let us consider the effectiveness of implementing the system of electronic document turnover.

After the test period, the results were evaluated by the following parameters:

1. Dynamics of the period from issue of invoice to acceptance of invoice by the customer.
2. Dynamics of the period from issue of invoice to acceptance of invoice by the customer in view of corrections in the invoice.
3. Dynamics of loss of invoices.
4. Customers' satisfaction with the system of electronic document turnover.
5. Evaluation of convenience of Diadoc by company's employees and customers.

The indicator "dynamics of the period from issue of invoice to acceptance of invoice by the customer" was studied by measuring the work days from the date of issue of invoice to the date of acceptance of invoice by the customer (in case of standard document turnover, the last date—date of delivery of the documents by a

courier, in case of electronic document turnover—date of customer's acceptance of invoice in Diadoc). Table 3 shows the data of the research of the indicator.

Thus, there is a clear difference between the average indicator on transfer of invoices in the period of use of standard document turnover and in the period of test of electronic document turnover. The terms reduced to one day—i.e., invoice is delivered to customer in the day of its issue. Based on the results, it is possible to speak about effectiveness of the project and about the correspondence of the system of electronic document turnover to the set tasks.

Detailed study of the results shows that though indicators of June are lower than in previous months, they do not achieve the target value (one day). This is due to the fact that June was the first test month, as company's employees and customers required time for adapting to a new form of document turnover. The results of two last months reached the set goal.

Dynamics of the period from the moment of issue of invoice to acceptance of invoice by the customer, in view of corrections in the invoice, are shown in Table 4.

This indicator was calculated from the moment of issue of invoice to the moment of acceptance of the correct invoice by the customer (issue of invoice—transfer of invoice—verification of invoice by customer—feedback regarding an error—correction of invoice—transfer of correct invoice—acceptance of invoice by customer).

During standard document turnover, the risk of loss of documents grows, and transition to electronic document turnover should have fully solved this problem. Table 5 presents the results of evaluation of this indicator.

The data of Table 5 clearly show the positive results of implementation of electronic document turnover. Loss of invoices is overcome.

Customers' satisfaction with the system of electronic document turnover is one of the key indicators. The project group conducted monthly surveys of customers and determined their satisfaction with Diadoc; also, it collected costumers' feedback and implemented their offered. A ten-point scale was used for convenience of evaluation.

The surveys among customers showed that all three customers gave the highest score. There were certain problems during synchronization of Diadoc with the customers' programs. The drawbacks dealt with, and the customers were satisfied with the program in the end.

Evaluation of convenience of Diadoc by employees of a company that strived for optimization of its employees' work time: Diadoc made the employees' work easier. After the test period, a survey among the employees regarding the program's convenience and its effectiveness was performed. All employees who worked with Diadoc noted that it made working with invoices easier and were satisfied with the novelty.

Transfer to the system of electronic document turnover allowed minimizing the expenditures for document turnover and improving control over the transfer of invoices and documents to customers and correctness of the documents. Employees' KPI became more objective and precise.

Table 3 Dynamics of the term of invoices' transfer

Customers	Term of invoice transfer									
	Standard document turnover						Electronic document turnover			
	January	February	March	April	May	Average time	June	July	August	Average time (electronic document turnover)
Customer 1	4	5	4	4	7	5	2	1	1	1
Customer 2	3	3	5	6	4	4	3	1	1	2
Customer 3	2	4	4	7	3	4	2	1	1	1

Table 4 Time of transfer of invoice in view of an error

Customers	Time of invoice transfer (with an error)									
	Standard document turnover						Electronic document turnover			
	January	February	March	April	May	Average time	June	July	August	Average time (electronic document turnover)
Customer 1	7	10	6	6	8	7	3	2	1	2
Customer 2	5	8	7	4	5	6	3	1	2	2
Customer 3	4	6	6	8	12	7	2	1	1	1

Table 5 Lost invoices

Customers	Number of lost invoices									
	Standard document turnover						Electronic document turnover			
	January	February	March	April	May	Average time	June	July	August	Average time
Customer1	12	6	3	2	5	6	0	0	0	0
Customer2	3	0	0	2	1	1	0	0	0	0
Customer3	1	3	0	1	0	1	0	0	0	0

4 Conclusions

Thus, a tendency of digitization's influence on growth of GDP and effectiveness of organization's activities was determined; advantages of electronic document turnover for a modern organization were analyzed; effectiveness of implementation for a specific organization was determined.

Implementation of a new information system led to positive results. Thus, the following decisions were made:

1. Working in the system of electronic document turnover on a constant basis with the customers who passed the whole test period.
2. Offering ten customers of the organization to work in the system of electronic document turnover.
3. Transferring the work with invoices and other documents to the new information system.

Thus, successful implementation of electronic document turnover is one of the significant factors of increasing the effectiveness of organization's activities in the conditions of the economy's digital transformation. It is obvious that electronic document turnover will be increasing its dissemination and will ensure a breakthrough in increase of speed and effectiveness of company management.

Cyber Security in the Era of COVID-19: Threats to Digital Platforms Stability and Cyber Hygiene Rules

Vyacheslav V. Burlakov, Evgeniy V. Skubriy, Lyubov N. Orlova, Gilyan V. Fedotova, and Aleksandr V. Sukhinin

Abstract **Purpose/objectives**: the article is devoted to a study of the public life reshaped in the era of COVID-2019 that has become a developmental milestone for the modern world. The COVID-19 is called a Black Swan event that is hard predicted and rare, but has significant consequences for the world economy and other spheres of human life. The authors investigated situations of social distance, self-isolation, quarantine, as well as digital interaction platforms being developed, and their cyber resistance. **Methodology**: the work applied methods of regulatory analysis and assessment of the current situation of broken virus infection chain to avoid a peak in COVID-19 cases and prevent overloading the public health system affected by the pandemic; comparative and trend analysis of statistical data; content analysis methods; formalization and analogue methods; and datasets of the Institute of Scientific Communications. **Results**: the analysis of the implemented information

1 Introduction

According to the report "Digital 2020" on the development of the Internet prepared by the Wearesocial agency and the SMM Hootsuite platform, by 2020, the number of Internet users had amounted to 4.54 billion people in the world, including 118 million people in Russia. In January 2020, there were 5.19 billion mobile users in the world; the mobile penetration in Russia made 163% of the total population. Wearesocial and Hootsuite counted about 70 million people in social networks in Russia.

In the era of COVID-19, the Internet is turning from a pleasant addition to social interaction into the major provider of interpersonal contacts for the vast majority of the population isolated. Deprived of opportunities for personal communication, we use software tools for establishing interaction, i.e., video conferencing systems, instant messengers, social networks, and other digital platforms. This cannot but affect the increasing role of the global Internet, information technologies, and digital platforms in our daily lives. They manifest themselves, in particular, in a considerable increase in Internet traffic.

There are following reasons for the substantial increase in Internet traffic:

- the switch to remote working for all staff, which involves Internet interaction;
- the switch to distance learning for schoolchildren and students via the Internet;
- an increase in supply and demand for food and non-food delivery services, as well as for services provided remotely (payment services, educational services, and services of state and municipal authorities);
- an increase in demand for entertainment video and game contents hosted on digital streaming platforms (Netflix, Disney, Amazon, Tvitch, etc.); and
- forced expansion of interpersonal interaction in the virtual space of social networks and instant messengers (Facebook, Instagram, VK, Whatsapp, Viber, etc.).

As follows from the NOKIA press release dated March 20, 2020, after quarantine measures enforced by Western European states, the traffic in the networks of Western European providers grew by 30–45% compared with previous annual indices. Unprecedented growth was demonstrated by video conferencing that made 300% of the previous values and the gaming industry with 400% of the previous values.

According to thebell.io, the self-isolation regime and an increase in distance jobs and distance learning caused the growth of the Internet traffic of major providers by 10–30% in Russia. MTS recorded an increase in traffic of video files by 40% in the metropolitan area, of instant messengers and social networks four times, and the game traffic doubled. The Internet traffic is mostly growing in fixed broadband Internet access networks in the daytime in residential areas.

Thus, the peculiarity of the Internet used in the era of COVID-19 is the redistribution of information flows in favor of fixed broadband networks intended for private rather than corporate consumers. Experts are of the opinion that considerable load on broadband access networks in residential areas and an increase in mobile Internet traffic in the suburbs of Moscow and St. Petersburg can lead to a decrease in Internet connection speed in these cities.

Moreover, according to experts of the World Economic Forum, the COVID-19 pandemic has exposed the "digital inequality" between poor and rich states and communities. Douglas Broome—Senior Writer of Formative Content—pointed out in his article, that about 3.7 billion people in the world do not have access to the Internet. In the richest countries in the world—the USA and Australia, 6% and 13% of the population, respectively, do not have access to the broadband Internet. In the United States, it makes 21 million people. Meanwhile, according to some political activists, access to the broadband Internet networks is an inalienable human right.

In Russia, some elements of the law of access to the Internet were proposed by President of the Russian Federation V. V. Putin in January 2020. He offered a program "Accessible Internet" that implied the right for unhindered and free access to socially important Internet resources for all inhabitants of Russia. According to the head of the Ministry of Communications of the Russian Federation M. Shadayev, in the current situation with COVID-19, the availability of Internet access for people in self-isolation is a basic need. The pilot project "Accessible Internet" was launched by the Ministry of Communications of the Russian Federation from April 1, 2020 to July 1, 2020.

2 Materials and Method

The high demand for digital interaction platforms, including social ones, forced us to look for qualitatively new solutions of the problem of preserving private information transmitted through networks. Increased hackers' attacks on all systems of interaction, both official and social, do not allow the information environment to function effectively. The measures taken by the state to maintain the integrity of servers and

databases are often declarative in nature, which makes companies and private users search for solutions of the issues by themselves.

The authors [1–7] dealt with the issues of the information economy, economy of knowledge, and intelligent platforms being developed in this environment.

Russian scientists [8–18] addressed the issues of digitalisation and modernization of public life and various sectors of national economy in the current pandemic and crisis environment.

The world community is concerned about the current situation in the world and problems associated with the quarantine measures and social disunity. A large number of publications on this topic prove current interest and concern of the scientific community. Increasing epidemiological threats are an irreversible process that can only be partially controlled and restrained by the efforts of all world powers.

3 Results

In the context of the coronavirus pandemic, an increase in cybercrime is recorded. According to the Organized Crime and Corruption Reporting Project (OCCRP) by reference to Europol and the US Cybersecurity and Infrastructure Security Agency (CISA), cybercriminals may use phishing attacks and misinformation due to the population's concern about the coronavirus epidemic.

According to the FBI's Internet Crime Complaints Center (IC3), as of March 20, 2020, the IC3 reviewed more than 1200 complaints of cybercrime related to COVID-19.

In Russia, cybercrimes increased by 84% in I Quarter of 2020 compared with I Quarter of 2019 and made 20% of all crimes committed.

The most common cybercrimes related to COVID-19 are

- sending phishing letters on behalf of supposedly public authorities that propose state funding and demand the recipient's personal data and bank card data;
- sending letter viruses or ransom ware viruses on behalf of supposedly authorities that inform about the COVID-19 pandemic and offer to follow the link or upload files;
- creation of scam sites that mimic existing popular services for video conferencing (Zoom, Webex, and GoToMeeting), misinform the population about the spread of COVID-19, treating, and preventing this disease, and offer fake or non-existent products to combat COVID-19, such as protective masks, medicines, or personal protective equipment;
- dissemination of unverified or untruthful information about COVID-19 disease and fraudulent offers on testing, treatment, and prevention of coronavirus on social networks;
- hacking video conferencing systems and remote work using vulnerabilities, including zero-day vulnerabilities for receiving personal and other sensitive data;

- hacking the Internet resources of healthcare institutions to purloin personal data, including medical records, social security numbers, insurance policies, and patient records;
- DDoS that are attacks on the Internet resources of state authorities, local self-government bodies, and international organizations in connection with the electronic pass system imposed, financial resources distributed in healthcare, and a wide range of issues related to the COVID-19 pandemic;
- creation, issuing, and sale of fake digital passes, medical certificates, and other digital and analog official documents to avoid being held liable for violation of self-isolation and quarantine; and
- ransom ware used against health facilities for complex automated patient care systems, including Artificial Lung Ventilation, being destroyed.

The explosive growth of cybercrime in I Quarter of 2020, in our opinion, is due to a number of reasons, including

- telework of a considerable number of employees;
- Internet technologies expanded to maintain social connections (social networks and instant messengers);
- the online stores supply increased during the period of self-isolation, including services for the sale and delivery of personal protective equipment, medicines, and consumer goods;
- increased number of Internet users for work purposes, public services, and entertainment;
- population unprepared for work on the Internet and the lack of basic knowledge in the field of Internet security or critical perception of information from the Internet; and
- extraordinary nature of the COVID-19 event that caused a sharp increase in Internet users and inability of state actors to protect citizens from cybercriminals' attacks, provoked general panic among the population, and made citizens search for any opportunity to ensure health and well-being during this period.

However, as cyber threats associated with COVID-19 increase, awareness of the problem is also rising, and measures to counter cybercrime are being developed.

State authorities of various countries and international organizations issued recommendations on protection against cyber threats.

For example, the Australian State Cybersecurity Center (ACSC) recommended the following rules of working remotely:

- critically treat received letters, messages, and phone calls and not open letters from unverified sources;
- be wary of any requirements for the rapid information about personal data, bank cards, passwords, etc.;
- use different passwords for different Internet resources, as well as multi-factor identification;
- update software and track automatically updating operating systems;
- use a VPN and verified Wi-Fi networks;

- not allow other people to use personal gadgets;
- avoid using an external storage medium; and
- use proven sources of information.

The European Union's Emergency Cybersecurity (ENISA) provided similar advice for companies that organize telecommuting jobs. The ENISA recommended using corporate hardware (computers, laptops, and tablets) and securing corporate networks to organize remote work, if possible.

In the Russian Federation, only the Central Bank of Russia developed measures to ensure cyber resistance and information security in the context of the new coronavirus infection (COVID-19). In the Information Letter no. IN-014-56/17, the RF Central Bank recommended banks and non-banking financial organizations to ensure the VPN technologies, multi-factor authentication, and terminal access in organizing remote access to financial transactions and remote work and provide monitoring remote mobile users.

Unfortunately, by the time the article was prepared, neither the Ministry of Digital Development, Communications and Mass Media of the Russian Federation nor the Government of the Russian Federation had made any recommendations for citizens and organizations on cybersecurity in distance work and study during the period of self-isolation.

This is all the more depressing because of an increase in cybercrime, including fraud using personal data of Russian citizens against the background of the COVID-19 pandemic.

Meanwhile, we believe it is advisable to widely inform Russian residents about the risks in the field of cybersecurity precisely in the current period, when many people use the Internet in remote work through insecure home broadband access networks on home computers or laptops without professional spam filters and not supported by a full-time system administrator. Government bodies should inform Russian citizens and organizations, especially those related to micro-enterprises and small businesses, about cyber threats that have increased due to the COOVID-19 pandemic, and about the need to follow recommendations in order to prevent and stop the massive spread of computer viruses and other malware.

It seems necessary to introduce elements of "cyber hygiene" into everyday practice of people and organizations and disseminate them at the national level. The cyber hygiene implies Internet behaviour patterns that provide effective protection against malware and malicious acts of cybercriminals.

The cyber hygiene was first voiced by Vinton Gray Cerf—the father of the Internet—in his speech to the US Congressional Economic Committee in 2000. In his opinion, the vast majority of vulnerabilities arise, when companies, government agencies, academic institutions, and people use the Internet, but do not apply good cyber hygiene. In the context of security, the openness is both a blessing and a curse for Web at the same time.

Best practices in cyber hygiene include

- antivirus programs, spam filters, and brandmauers installed and properly configurated;

- proper functioning of routers and firewalls ensured;
- operating systems, software applications, web browsers, and corporate programs updated with the latest security patches;
- regular Whitelist updating for every new application and strengthened isolated user permissions for authorized users;
- a strong password or multi-factor authentication; and
- physical segmentation of computer networks ensured through secure routers and active firewalls.

We believe that the cyber hygiene rules are a pressing necessity in the period of COVID-19 pandemic and growing cybercrime. These rules and practices are partially formalized in the Russian regulatory system related to information security, for example, GOST R IEC 62443-2-1-2015 "Industrial communication networks. Network and system security." The rules however need to be simplified and adapted to an ordinary person, since in their current form they are difficult to understand for the average Internet user.

We believe that the cyber hygiene practice disseminated in Russia should be monitored by a separate agency in the structure of the Government of the Russian Federation, similar to the Cybersecurity Agency of the European Union or the Cybersecurity and Infrastructure Protection Agency of the United States. Its competence would include issues of cybersecurity and enforcement rights of Internet users in Russia.

4 Conclusion

The need to maintain social distance and self-isolation regime required the state agencies to make decisions related to ensuring control over the behavior of the population. Many countries set fines for violating the self-isolation regime, refusing to wear masks, and leaving apartments and houses for no good reason. In Russia, the measures to exert the population's discipline were legalized by Federal Laws no. 98-FZ dated April 1, 2020 "On Amending Certain Legislative Acts of the Russian Federation on the Prevention and Response of Emergencies"; no. 99-FZ dated April 1, 2020 "On Amending the Code of the Russian Federation on Administrative Offenses"; and no. 100-FZ dated April 1, 2020 "On Amending the Criminal Code of the Russian Federation and Articles 31 and 151 of the Code of Criminal Procedure of the Russian Federation" that broadened the RF government's powers to put restrictions concerning the COVID-19 pandemic and imposed administrative and criminal responsibility for violating the extraordinary rules and norms provided for the isolation.

In order to provide automatic control over citizens' compliance with the restrictive rules in various countries, there are automatic fixation and identification systems, including street video surveillance systems and tracking systems for phones and smartphones. For example, in China, the Alipay Health Code software product was developed and implemented, when each registered resident of China received a color

code—green, yellow, or red—that determined his/her state of health. A green code person could move without restrictions, while the owners of the yellow and red codes had to be isolated for a week or two. Road video surveillance systems made it possible to track intruders traveling by road. The social networks WeChat and Weibo widespread in China opened their hotlines where users were suggested to report on violators of the regime.

Similar measures were introduced in other countries affected by the COVID-19 pandemic. For example, in France, the authorities ordered all residents to have a notification about reasons for going out. There were also QR codes introduced for the French to move outside the house or apartment. In Singapore, TraceTogether allowed establishing a circle of people who have contacted a patient and is used to track the contacts of coronavirus patients.

Some regions of the Russian Federation—Moscow, Tatarstan, etc.—introduced automatic systems to control the self-isolation regime. In Moscow, a system of digital passes was issued for all Moscow residents to travel around the city by car from April 13, 2020. This system is an alphanumeric code that can be received by a user authorized on the state resource mos.ru and is designed to track movements of Moscow residents during the period of restrictive measures. The Moscow authorities imposed administrative responsibility for violation of these rules and fixed these violations by means of visual road control.

All these measures allowed reducing the contacts between people, preventing the infection growth, and thereby decrease in the COVID-19 mortality during the peak of the coronavirus cases. The objectives of these events are more than good.

However, some experts and human rights groups expressed fears that all these technical means of monitoring the population can be used not only to combat COVID-19, but also to monitor citizens and their lives, collect personal data, and limit their rights and freedoms.

It seems extremely important to find a balance between the need to ensure compliance with the imposed restriction regime, the necessity to ensure human rights and freedoms, and the need to ensure cybersecurity in the broad sense in order to prevent the means of technical control of information about citizens and their personal lives from being illegally used.

Mergers and Acquisitions in the Russian Economy: Peculiarities and Patterns

Svetlana A. Varvus, Anzhelika P. Buevich, and Stanislav Yu. Buevich

Abstract Mergers and acquisitions play a dual role in the development of national economies. On the one hand, the quantitative and value assessments of transactions should directly affect the capitalization of the stock market, but the Russian economy is exposed to political risks than economic ones to a greater degree. On the other hand, concerning the impact of determining factors (GDP, interest rate, changes in law, taxation system) we can discover specific conditions of the M&A market in Russia. Over the past decade, the Russian M&A market has been multidirectional. Due to the imposition of sanctions, the devaluation of the ruble, and increased key interest rate in 2015, the M&A market demonstrated the worst indicators. In 2018, the Russian M&A market showed moderate growth, as far as the Russian economy managed to adapt to external challenges (unstable geopolitical situation, insignificant economic growth, and lower interest rates). These factors will have a lagged effect on the M&A industry as a whole. Most Russian companies do not place shares on the stock exchange, therefore the correlation between capitalization of the stock market and the total value of transactions is only 0.244. The structure of the M&A market indicates the prevalence of acquisitions in the Russian market. The Russian stock market is underdeveloped than in the West, and the Russian securities cannot be regarded in the long term as a liquid payment instrument.

Studies in Systems, Decision and Control 314,
https://doi.org/10.1007/978-3-030-56433-9_163

In the fast-changing conditions, the company often faces the challenge of working out new ways of business development. Thanks to the digital economy opportunities (blockchain technology, the Internet of things, virtual and augmented reality, artificial intelligence), corporate management can increase the efficiency of large firms and reduce transaction costs. In particular, the management can contribute to the decision on mergers and acquisitions (M&A) as an advantageous solution for business development.

Mergers and acquisitions allow companies to increment capital and respectively the profitability, expand the target markets where they supply products and enhance the competitive advantages in general. Today, at least one M&A transaction is effected every day. Entrepreneurs spend money not on the arrangement of new production, but the acquisition of financial assets of companies operating in the market [1].

The problems aimed at the further appreciation of the corporate value require the information on the processes occurring in this market, factors contributing to the merger of companies, measures for making successful transactions with regard to Russian peculiarities. That's why the analysis of arranging M&A transactions in Russia is of current importance.

Along with that, the ideas about mergers and acquisitions in the system of public reproduction are still split. The issues of the economic nature, reasons, and goals of transactions concerning modern Russian conditions have been underdeveloped. This concerns the qualitative and quantitative determination of corporate value.

1 Methodology

The relevance of the paper is in the role of mergers and acquisitions in the development of national economies. Therefore, the authors have attempted to explore the Russian M&A market, as well as the reasons for their occurrence. The authors have transactions with the theoretical points of the range of issues under study in view of the current state of the M&A market. For the study, the authors outline the following objectives:

1. to investigate the economic nature of M&A transactions;
2. to explore the reasons for mergers and acquisitions;
3. to carry out a comparative and industry analysis of M&A transactions in Russia;
4. to reveal the peculiarities of the international and Russian M&A markets and draw conclusions.

The information base of the paper was the reference and statistical data of Rosstat, Bloomberg Professional, the Emis information platform, reviews made up by AK & M information agency, periodical publications, and calculations of scientists and practitioners.

When studying the economic literature on this issue, the authors faced with the fact that there are several approaches to determining the economic nature of the M&A market. Thus, R. Brenley, M. G. Iontsev, A. D. Radygin, D. Depafilis in their

works distinguish between "mergers" and "acquisitions". The mergers mean the establishment of a large company through amalgamation, and the other companies cease their operation. The second group of economists (P. Gohan, S. Bragg, A. R. Lajou, N. B. Rudyk, A. E. Molotnikov) proceeds from the assumption that there is no difference between "merger" and "acquisition" and see them synonymic. In their opinion, mergers and acquisitions are considered in a broader context, including, inter alia, other forms of company restructuring: the acquisition of separate parts of the business, strategic participation in the corporate capital, loaned buy-out, and other forms [2–6].

2 Findings

Under the Civil Code, a merger is understood as a reconstruction of a legal entity with the approval of the founders. The rights and obligations of each of the companies are transferred to the newly established legal entity by virtue of a deed of transfer. Upon termination of a transaction, the new legal entity put in the books all company's financial obligations, as well as assets. A distinctive feature of the foreign practice is the non-establishment of a new legal entity in the merger. The transaction is effected by the institution of mediators who accompany the entire transaction until the end. In Russia there is no this kind of institution, only lawyers or top managers can perform their functions.

Upon acquisition, the control function is transferred from one company to another. In Russian practice, the stock buyout is prevailing. The two companies turn into single one through the acquisition: the purchasing company acts on the market as an independent legal entity, and the target company ceases to exist.

In the course of mergers and acquisitions emerge two economic agents: the purchasing company and the target company with various goals and causes of action. In foreign economic literature, there are over a dozen of motivational theories of mergers and acquisitions. They include both the theory of market power/monopoly, and transaction costs, and empire construction, and synergies, and agency costs of free cash flows, and false pride, and raiding, etc. Three main theories (false pride, agency costs of free cash flows and synergistic) prevail among Russian economists. According to the first theory (false pride), the management of the purchasing company acts in its interests, seeks to gain the highest possible profit at the expense of business owners. Such behavior is represented in the theory of agent relations and it results in a conflict of interests between the principal and the agent. In the second theory (agency costs of free cash flows), the management spends overage of money on the purchase of another company to increase the resource base, but not on payment of dividends to the principal. Finally, the synergetic theory implies that the reason for mergers and acquisitions is to increase the aggregate value of the merged companies from transferring control of the company's resources to the target company. Here, the company's management is acting in the interests of the principal (business owner).

A synergy effect can be achieved through the economies of production scale, higher market share, market power of the company and more efficient management [7].

It should be noted that acquisitions prevail in the Russian market. And this is no accident. It is often more advantageous and easier to buy the shares of the target company (if the value of these shares is not so high that it falls under the terms of a major transaction) and the decision on the acquisition can be considered only with the board of directors (a meeting of shareholders is not required), which greatly facilitates the process. Regardless of the transaction's value, the merger requires a general meeting of shareholders, and both companies must vote for the merger.

The economic consequences of mergers and acquisitions suggest savings from scale of production, high-cost innovation and investment; getting the synergy effect; diversification of the company's areas of activity. The disadvantages of mergers and acquisitions are the high financial costs for payment of bonuses to shareholders, company staff, the high risk of the wrong valuation of the company, complicated integration of companies specializing in different industries, etc. [8]. Now we will start to describe the mergers and acquisitions in developed countries (mainly in the USA).

Mergers and acquisitions in the United States have been existing over 100 years and a significant proportion of the resources are changing owners. The corporate capital market induces the flow of new investment in the economy. Such processes provide the greatest return for all investments, as well as the intensive redistribution of available resources between different sectors of the economy. The global M&A market is multidirectional. The record number of transactions was made in 2004. This is connected with the accelerated economic growth in the world, business confidence, and tax reform in the United States. Recently, we have been observing a positive trend both in the number and in the cost of M&A transactions (Fig. 1).

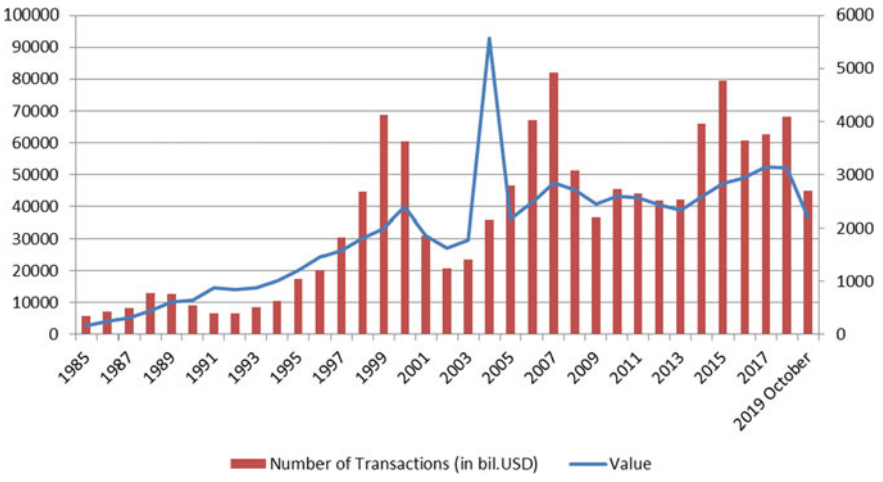

Fig. 1 The volume of M&A transactions in the global market in 1985–2019. *Source* Made up by the authors based on data from www.imaa-institute.org

The leader in the corporate M&A market is the United States (Fig. 2). Besides, the United States accounted for 56.5% of the global M&A market in 2018.

Due to the accomplishment of the goal set (conducting a comparative analysis of the American and Russian M&A markets in 2013 and 2018) we outlined the specific features of the markets. Thus, in the USA, 10,862 transactions of 1,186.201 US dollars were made in 2013 (Fig. 3). Over the same period, 533 transactions were effected in Russia, which is 20.3 times less than in the USA. Investigating the current state of M&A, we can note that in 2018 17,582 transactions were made in the USA against 948 in Russia. The value of transaction is 61 times less than in the United States, where the value appraisal is 2,053.7 billion US dollars [9].

Economists explain the fast-growing number of M&A transactions in the USA for the end of the twentieth century by various types of taxation both in the short and

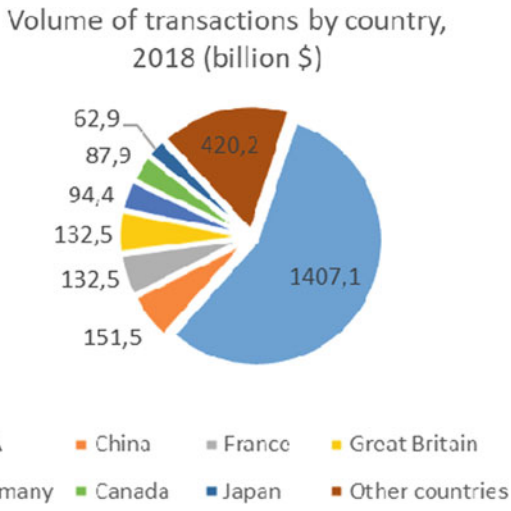

Fig. 2 The volume of M&A transactions in the global market in 1985–2019. *Source* Made up by the authors based on data from www.imaa-institute.org

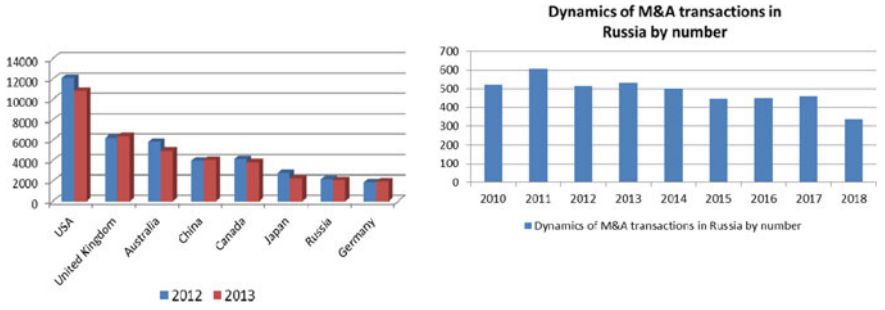

Fig. 3 The number of M&A transactions in the USA and Russia in 2013 and 2018. *Source* Made up by the authors based on data from www.imaa-institute.org

long term. This circumstance contributed to the rapid exchange of company assets in the short term under low transaction costs.

The Russian M&A market differs from the American one in the value of transactions, both in quantitative and in value terms. Companies under Russian jurisdiction preferred to close transactions in medium and small sectors, rather than large ones, on the one hand, to cement its position in the market when capturing it to a greater extent, on the other hand, to protect its financial assets from further devaluation of the ruble.

The next peculiar feature is the non-public nature of information. The business community is not always fully aware of all points of transactions: what are the sources of funds for mergers and acquisitions, what is the exact value of the transaction.

A specific feature of the Russian M&A market is the concentration of property with high state participation in various transactions because 2/3 of the M&A market accrue to the major shareholders. Thus, due to sanctions in 2018 Sberbank had to sell the Turkish subsidiary company Denizbank to the Emirates NBD banking group (UAE) for 3.2 billion US dollars, VTB-Capital bought shares of a large Russian retailer Magnit for 2.45 billion US dollars with subsequent resale, having brought its share to 18.2% of the Russian M&A market. Therefore, it can be stated that the behavior of Russian investors is aimed at the short term and profit-taking (Fig. 4).

As the chart analysis showed, the exponential growth in the Russian M&A market in 2013 can be explained by a major transaction when Rosneft acquired TNK-BP (the largest company in the fuel market). The transaction value amounted to 54.98 billion US dollars. It is obvious that this transaction completely has beaten the value of 2012 from the total number of contracts concluded (Fig. 5).

Let us highlight that the average value of the transaction in Russia in 2018 increased to 65.7 million dollars, which is 14.5% greater than the same indicator for 2013 and has been the highest value for the last decade. Decreased average

Fig. 4 M&A transactions in Russia in 1993 and 2018. *Source* Made up by the authors based on data from www.imaa-institute.org

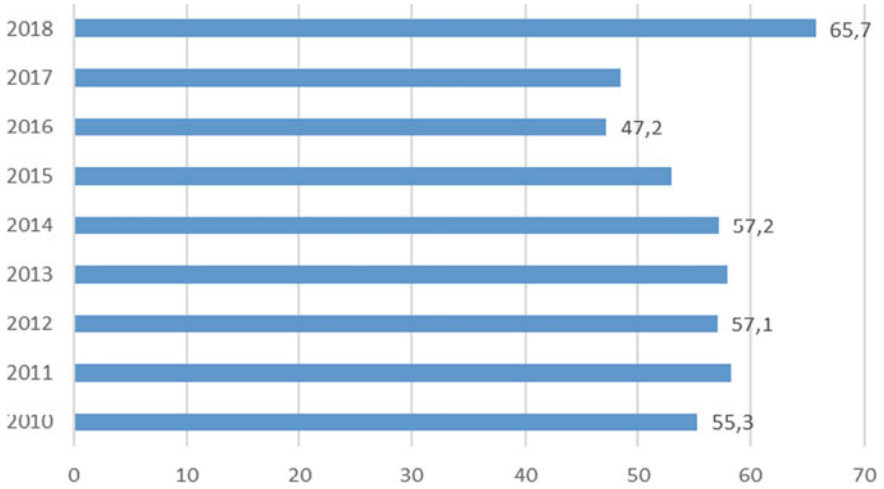

Fig. 5 Dynamic trend of the average value of M&A transaction in Russia since 2010–2018, million US dollars. *Source* Made up by the authors based on data from www.akm.ru

value of the transaction from 2013 to 2016 reflects demonstrates a lower number of mega-transactions.

The indisputable distinguishing feature of the Russian M&A market is the peculiarities of the industry. In 2013, transactions were prevailing in the fuel and energy sector (both by the number and value appraisal—65.386 billion US dollars), telecommunications and the electric power industry. Major transactions related to the company's entry into the Tele2 Russia market in the total value of 4.8 billion US dollars were made. In the electric power industry, Gazprom Energoholding acquired MOEK (Moscow United Energy Company), having bought out 90% of the shares, which gave it an opportunity to occupy the third position (transaction value is 2.7 billion US dollars).

In 2013, major M&A transactions in Russia were closed in the service and information technology sectors. Such a development is associated with the macroeconomic situation in the economy, i.e. economic depression, slowing down industrial growth from 0.7 to 0.1%. 2013 in Russia is characterized by a lower number of M&A transactions in industry and a higher number in infrastructure fields (finance, construction, communications). The reason is a decreased industrial production index, as well as investment flow in fixed assets by 7%. That is why this industry turned out to be unattractive for investment.

In 2013, domestic transactions with a share of over 80% of the total transaction volume prevailed on the Russian M&A market. The year 2018 is marked by own shares' buyout, which accounted for about 15 percent of the total value of M&A transactions. [10]. Investors prefer to invest in the domestic market since nobody wants to take risks both due to political factors (sanctions, the trade war between the USA and China, the Brexit repercussions), and economic factors (the US Federal

Reserve System's policy on the dollar exchange, international capital flows, etc.) (Fig. 6).

The US market was prevailed by sectors such as healthcare, power industry, high technology, financial institutions, etc. Major transactions in the United States include the purchase of Express Scripts Holding Co pharmacy network by the US insurer Cigna Corp for 67 billion US dollars, as well as acquisition share in RWE AG for 38.5 billion US dollars by German E. ON SE from Innogy (Fig. 7).

The differences revealed allowed the authors to identify the role of mergers and acquisitions in the Russian economy. They also stated a hypothesis on the dependence of the M&A market development and changes in the capitalization of the

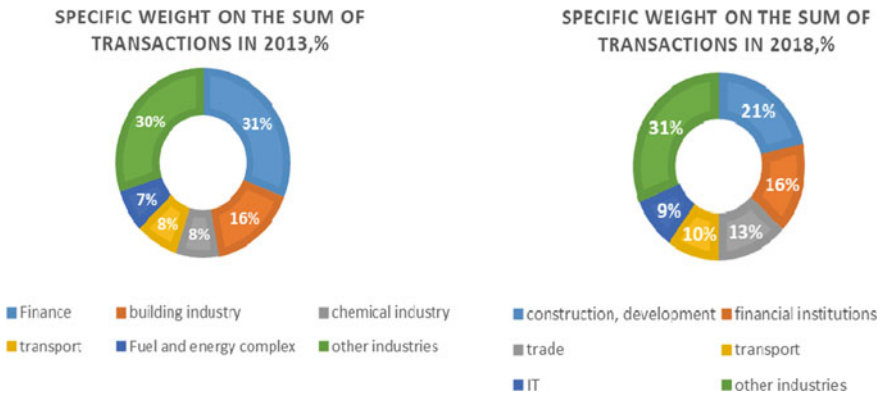

Fig. 6 Specific weight on the value of transactions in 2013 and 2018 (%). *Source* Made up by the authors based on data from www.akm.ru

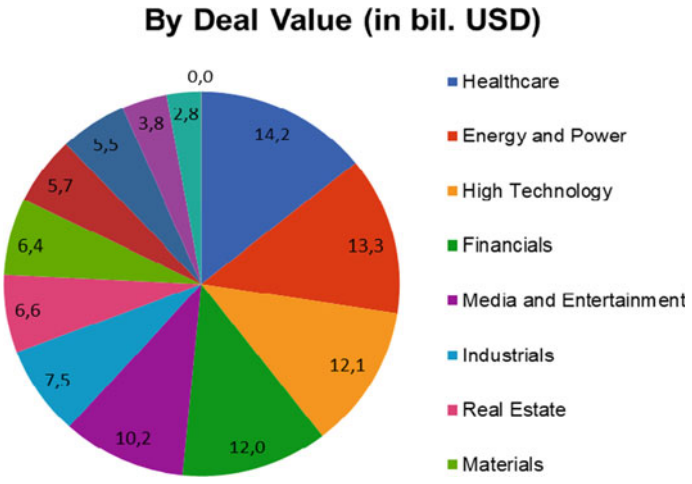

Fig. 7 M&A transactions by value in the USA in 2018 (%). *Source* Made up by the authors based on data from www.imaa-institute.org

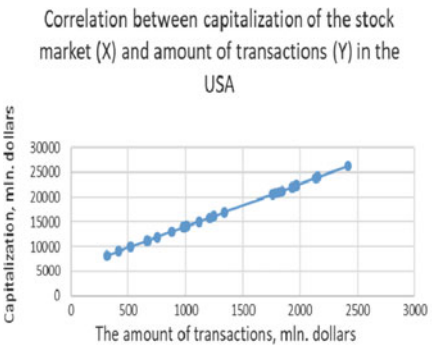
stock market, since the target company under acquisition is purchased via the stock exchange. Many experts uphold the principle of materiality between these indicators.

Based on the statistical data provided by www.knoema.com and www.imaa-institute.org, a sample was drawn up by stock market capitalization indicators and a value appraisal of M&A transactions for the Russian and US economies. The final correlation allows concluding that the value of transactions under M&A has an impact on the figure of the US GDP, while the correlation coefficient is 0.497. The US market is responding quickly to changes due to the widespread company's stock buyback strategy. As for the Russian model, currently, it's not much influenced by the transaction value and the stock market capitalization, since the correlation coefficient is 0.244.



CAP_{usa}=5,468,883+8,584M&A $_{usa}$

CAP_{rus}=103,176+4,067M&A$_{rus}$

3 Conclusion

In conclusion, we would like to note that mergers and acquisitions play a dual role in the development of national economies. On the one hand, the quantitative and value assessments of transactions should directly affect the capitalization of the stock market, but the Russian economy is exposed to political risks than economic ones to a greater degree. On the other hand, concerning the impact of determining factors (GDP, interest rate, changes in law, taxation system) we can discover specific conditions of the M&A market in Russia [11]. Over the past decade, the Russian M&A market has been multidirectional. Due to the imposition of sanctions, the devaluation of the ruble, and increased key interest rate in 2015, the M&A market demonstrated the worst indicators. In 2018, the Russian M&A market showed moderate growth, as far as the Russian economy managed to adapt to external challenges (unstable geopolitical situation, insignificant economic growth, and lower interest rates). These factors will have a lagged effect on the M&A industry as a whole. Most Russian companies do not place shares on the stock exchange, therefore the correlation between capitalization

of the stock market and the total value of transactions is only 0.244. The structure of the M&A market indicates the prevalence of acquisitions in the Russian market. The Russian stock market is underdeveloped than in the West, and the Russian securities cannot be regarded in the long term as a liquid payment instrument.

The Role of Factors for Development of Modern Socio-economic Systems in Evolvement of Value and Money Theories

Irina A. Guseva and Elena I. Kulikova

Abstract The purpose of the article is a modern view of the evolution of the theory of value and money. The main theories of value and money analyzed within the framework of the historical and genetic paradigm, the modification of the nature of money. The interrelation of productive forces and production relations determines the modern transformation of the quality of money. The factors of change in the content of the categories of value and money in each sotio-economic formation are revealed: concentration and centralization of capital, socialization of the economy, changing the nature of the product itself, financialization of the economy, Information Technology, new forms of organization of production and sotial activities. The transformation of the economy as a result of an objective global change in the world requires the development of a modern theory of money.

Keywords Value · Money · Monetary theory · The role of money · Modern theory of money

1 Introduction

The relevance of studying the nature of qualitative changes in the value and money theories is explained by deeper economic and institutional transformations, higher uncertainty in the development of complex socio-economic systems [1]. An analysis of the development of productive forces and production relations in the modern economy points at:

- decreasing role of money as a measure of social wealth and a means of exchange and distribution of benefits;

- distortion of the value of goods, as far as the intellectual component now plays a more important role in the labor costs for their production;
- new needs, relations, production mechanisms and technologies due to the economic digitalization, etc.

All these trends explain the transformation of the money quality and require the theory to be interpreted and evolved concerning the institutional factors influencing the economic and social systems.

2 Methodology

Monetary theory is a developing branch of economic science. Studying the patterns of money performance in practical terms lays the foundation for development of appropriate economic policy, elaboration of an effective monetary policy pursued by the Government and the Central Bank, building a modern market model of the economy on the back of international best practices [2, 3].

The scientific analysis of money was provided in the works of famous economists such as A. Smith, D. Ricardo, J. St. Mill, C. Marx, J. Keynes. The works by D. Hume served the base for the emergence of a quantitative theory of money. Basic research in this area is the writings by K. Menger, I. Fisher, A Marshall, A. S. Pigou, D. Robinson, M. Friedman, as well as of domestic economists like A. V. Buzgalin, A. S. Galchinskiy, V. P. Kazakevich, G. P. Solyus, G. A. Trakhtenberg, A. A. Khandruev et al.

B. Klein, F. von Hayek, O. Issing, as well as Russian economists M. Alekseenko, D. Kochergin, D. Lushchaev et al. examined in their proceedings the issues of non-state monetary emission that are of current importance for developing cryptocurrency regulation tools.

The authors employed a historical-genetic approach and classified key provisions of the money and value theories, which made it possible to trace the changes in the nature of money from ancient times till present.

3 Findings

(1) Attitudes to Money in the Era of the Ancient East

The money and the monetary form of wealth were investigated millennia ago. Each stage of the development of productive forces and production relations give rise to new theories. The groundwork for the emergence of value and money theories were laid in the period of manual labor and subsistence farming, in the era of the Ancient East (twentieth century BC to fifth century AD).

The laws of Hammurabi (eighteenth century BC) mention money and its substitutes. For example, one of the articles prohibits the sale of plot, house and a garden

belonging to the soldiers or servants of the king in exchange for silver. Restrictions regulating the annual interest rate in cash (20%) and kind (one third of the debt) are imposed on usurers, debt-serfdom is limited to 3 years" [4].

In ancient Egypt, the development of exchange trade leads to the emergence of equivalent goods, i.e. the value of goods is measured in weight units of copper and silver.

The heyday of commodity-money relations in ancient Greece and Rome leads to a philosophical and legal interpretation of the money phenomenon and related concepts. Xenophon of Athens (430–355 BC) describes some features of money in "Oeconomicus" and "Ways and Means". In the first work, he talks about the utility of money: "… money means nothing if you do not know how to use it… So if you do not know how, put it aside…to stop regarding it as property" [5].

Real and counterfeit money is already being considered in this period: "…if I asked you "is this silver coin real or not", could I make you believe that you can distinguish real money from counterfeit?" [5].

Xenophon pays attention to issues of growing government revenues, money augmentation (profit-making) and uses the category of capital: "As for the other possible incomes, I know that a certain amount of capital is required… On the contrary, only money paid by people on account of the required capital will bring them a huge benefit… Since one who pays one mine (an ancient coin of Greece) will gain almost two mines of income, and this takes place in city that is regarded the most reliable and durable of all the human inventions" [6] (from the investor's point of view, Xenophon correlates risk and return on investment).

Xenophon deems land also as a source of value: "…for people who know how to take care of business and cultivate the land hard, agriculture is the quickest way of enrichment" [6].

Plato (427–347 BC) represents the ideal state in "State" and "Laws". Plato calls agriculture the main source of wealth. Money plays an inferior role. It can be accumulated but cannot be used as a source of enrichment due to usury. Prices for goods are fixed by the state.

Aristotle (384–322 BC) suggested using a thing for own consumption and in exchange for another thing. The initial category is a human need. "There would be no relationship without exchange, as well as equalization—without exchange and commensurability—without equalization" [7].

The money (coin) occurs to replace the needs and make them commensurate. Aristotle outlines "Economy" (the field of material production, that is, agriculture and craft) and "Chrematistics" (from Greek "chremata"—the accumulation of wealth in trade and usury) condemned by him. Money facilitates trading.

In the Roman Empire (first century BC to fifth century AD), legal rules underlying the legal system for many modern states have been developed. They contain definitions of price, purchase, and sale, various types of loans and ways of securing them.

The first monetary reforms were introduced in Ancient Rome. Emperor Vespasian (ruled in 69–79s) levied taxes on public toilets to replenish the budget. Emperor

Diocletian (284–305) issued new full-weighted gold, silver and copper coins to prevent the depreciation of money.

(2) Nominalist Theories of Money: from Thomas Aquinas to Leon Walras

The development of trade, commodity-money circulation, and usury in the Middle Ages (fifth to sixteenth centuries) served a framework for the money theories. The nominalist one was the first. In the authors' opinion, the idea of nominalism lies in the provision that money is created by the state and their value is fixed and expressed in monetary denominations. The purchasing power of money depends on its face value, which is indicated on coins and banknotes.

The author of the nominalist concept of the money origin and nature is Thomas Aquinas (1225 or 1226–1274), who believed that the monarch establishes the value of the coin. Thomas Aquinas strongly disagrees with interest as a fee for money usage (with some exceptions).

In the seventeenth to eighteenth centuries, the nominalist theory of money was supported by the English economists J. Berkeley (1685–1753) and J. Stuart (1712–1780), and the German economist G. Knapp (1842–1926).

In Russia, the above-named theory appears in the eighteenth to nineteenth century. This was contributed by the establishment and reinforcement of the autocratic state, the development of the domestic market, and access to the world market. Entrepreneur Daniil Voronov (an associate of Peter the Great) believed that "it's necessary to issue wooden coins totaling 5 million rubles for 50 years instead of a metal one to encourage manufacturing industry" [4]. He reckoned that the purchasing power of money depends not on their value, but solely on the king's authority. N. M. Karamzin upheld extremely nominalist views: "If the monarch gave us branded chips and ordered them to use them instead of rubles, having found a way to protect us from counterfeit wooden coins, then we would have taken chips" [8]. The emergence of paper money in Russia in 1769 strengthened the nominalist positions.

The nominalist theory of money later declared itself in the theory of universal market equilibrium by L. Walras (1834–1910).

The main proceeding written by L. Walras is called "Elements of a pure political economy". It was him who applied for the first time mathematical methods to study economic processes. L. Walras explores the dependencies of economic phenomena as mathematical models using indicators of the volume of goods, various factors of production. L. Walras also developed the theory of general economic equilibrium as a "universal model of studying an integrated economic system. He defined general equilibrium as the state under which demand and supply in the markets of productive services and goods are equal, the price is stable, and the selling price of goods is equal to the costs expressed in productive services" [4].

In L. Walras's interpretation, "money is just a conversion factor for designation of developing exchange relations between goods on the market" [4].

(3) Bullionism (the Metal Theory of Money)

The idea of the metal theory is that the value of money depends on the value of the metal.

The purchasing power of money is estimated by the metal it is made of. The most expensive monetary units (coins) are made of gold or silver. Gold or silver establishes the great value of money due to its natural properties. The development of exchange is not related to the value of money. Such ideas were supported by the Professor of the Sorbonne Jean Buridan (1295–1358) and the royal counselor Nicolas Orezm (1325–1382).

In the eighteenth to nineteenth centuries, the commodity-metal concept of money as a means of fighting against Russian nominalism comes (V. N. Tatishchev, L. N. Radishchev, M. M. Speranskiy, and N. I. Turgenev were its proponents).

In the work "The Financial Plan" M. M. Speranskiy (1772–1839) presented to the fullest extent this concept, which became the theoretical foundation of the monetary reform of 1839–1843. N. I. Turgenev in "Essay on the Theory of Taxation" (1818) referred to the exchange of banknotes for low-quality coins as well as the existence of paper gold-unsecured money to as inflation factors. N. I. Turgenev followed the principles of state non-interference in market mechanisms and the independence of the national bank from the state. The metal concept had been the foundation for two monetary reforms in 1839–1843 (establishment of a silver monometallism system) and in 1895–1897 (resulted in a gold standard).

(4) Mercantilism

In the Age of Discovery, a global market is developing. Mercantilists have become the ideologists of the merchant class.

Mercantilism as a strand of economic thought proceeded from the identification of wealth with money. Mercantilists believed that silver and gold coins were a true wealth, and the wealth this was the money. In the period of early mercantilism, the idea of maximizing the cash flow from abroad into the country and preventing its export was prevailing. That is, the country needs an active monetary balance when the export of money should always be less than imports.

Florentine banker B. Davanzatti (1529–1606) is the author of one of the first writings on monetary circulation "The Doctrine of the Coin" (1522). In 1581, the English economist W. Stafford published the book "A Compendious or Brief Examination of Certain Ordinary Complaints of Diverse of Our Countrymen in These Our Days". He suggested to impose a ban on the export of gold and silver, effect state regulation of trade to prevent imports, support domestic manufacturers to combat the depreciation of money and consequently the deterioration of living standards.

A representative of late mercantilism Thomas Man (1571–1641) in his works reasoned that the export of money from the country is not always a negative occasion. It depends on the goals. If imports contribute to the development of the country's economy and the balance of foreign trade is positive, it is acceptable. T. Man regarded trade as the only source of enrichment and identified wealth with money.

In France, the concept of a positive trade balance was embodied in the policy pursued by J.-B. Colbert, Minister of Finance under the reign of King Louis XIV. The state encouraged the development of craft production to increase exports and employed protectionism.

(5) The Theory of Value and Money by K. Marx

K. Marx was one to enunciate the labor theory of value in detail, although the founders of the classical political economy like William Petty, Adam Smith, and David Ricardo suggested its various options.

Under this theory, the value of a commodity is estimated by the amount of socially-important labor expended for its production. The proportion of the exchange of one commodity for another depends on its value; it is reflected in the price through comparison with the equivalent commodity. Money acts as an equivalent commodity. The price of a commodity is a monetary expression of value displayed on the market in exchange (in a purchase/sale transaction). K. Marx studied the market economy in its most developed form at the time of research, the capitalist one that was based on private ownership of production means. K. Marx was trying to answer the question on the source of value and profit.

In K. Marx's opinion, wealth in the capitalist economy is represented by a huge accumulation of goods [9].

A commodity is a unity of value in use (utility) and value in exchange (characterizing the proportion of the exchange of one commodity for another). The value in exchange is based on the value that depends on the amount of socially-important labor expended on the production of this commodity. The production of commodities requires means, material, and supplies (fixed assets, which value is transferred to the goods manufactured), as well as workers (manpower). K. Marx understood labor as a commodity. Hiring workers, the capitalist pays a salary that is a converted form of the manpower value, i.e. capacity for work, but not payment for labor. During production, which is also a process of manpower consumption, the worker through his labor transfers the value of production means, materials, and supplies consumed to the goods manufactured as well as creates new value greater than the value of manpower itself.

K. Marx investigates the dual nature of labor. Any work is both abstract and certain. Also, labor is seen as simple and complex. The manpower value with advanced competencies (complex labor) is higher. Complex labor is a multiplied simple labor.

Thus, the value of the commodity manufactured in a capitalist production contains the surplus value created during the consumption of a special commodity (labor). Profit is a converted form of surplus value.

K. Marx stated the law of value, which idea lies in the fact that the proportions of the commodity exchange largely depend on the amount of socially-important abstract labor expended on the production. This is the basic law of commodity production working in any market economy. In a capitalist economy, the value of a commodity takes the converted form of the production cost.

The theory of money by K. Marx arises out of the theory of value. Money is a commodity, i.e. universal equivalent. Money has its own form transforming as commodity production is developing, and perform several functions.

The law of monetary circulation is the law regulating the amount of money in circulation. According to K. Marx's words, the amount of money in circulation

depends first and foremost on the sum of the prices for goods circulated in the market, the speed of circulation, loan value, and the amount of balanced out payments.

K. Marx assesses the manufacturing process from the perspective of the unity of productive forces and production relations, which act as a mode of production. Productive forces constitute the essence of the mode of production, and production relations (relations arising between people in the production, exchange, distribution, and consumption of material values)—its form. Commodity, value, money and other categories are examined by K. Marx in terms of production relations and property relations that have an impact on the means of production and products of labor. The development of these relations inevitably results in the emergence of its new forms.

(6) The Quantitative Theory of Money: from N. Copernicus to A. Marshall

Proponents of the quantitative theory of money address issues on changing purchasing power of money, its relative value, and amount in circulation.

N. Copernicus (sixteenth century) came to the conclusion that "money has become depreciated when their amount is far too much" [4].

The French lawyer J. Boden in 1568 in his work "Answer" proved that the overall price hike in Western Europe of the sixteenth century could not be caused by coin damage solely. The higher number of gold and silver coins in circulation evoked the price boom.

The mercantilist T. Mann put forward the idea underlying the quantitative theory of money: the amount of money in circulation depends on trade turnover, money is not only a treasure but also a means of exchange.

D. Hume (1711–1776) in the essay "On Money" cast the money in the role of exchange means. "Money is only a tool used by the common consent of people to facilitate the exchange of one commodity for another. This is not one of the wheels of trade, but oil making their movement smoother and easier" [10]. D. Hume first put forward and justified the statement on the "neutrality of money in the economy", and also examined the positive relationship between slowing prices (due to greater amount of money in circulation) and economic development.

D. Ricardo applied quantitative theory to paper money. "If instead of opening a mine in the country, the government established a bank (like an English one) which was able to issue banknotes as an exchange means, then issuing …a great number of banknotes, therefore, a significant amount of exchange means would result in the same situation as opening a mine. The means of circulation would fall in accordance with its value, and the goods would rise in price" [11].

J. S. Mill counted that monetary growth does not necessarily lead to a hike in prices since the commodity weight and reserves can also increase in the same proportion.

Representatives of the Neoclassical School based on marginalization supported the quantitative theory of money.

Marginalism as an economic theory is founded on the study of marginal values. The theory of marginal utility serves as an alternative to the labor theory of value. Following the above theory, the value of the commodity is determined by its marginal utility, i.e. one of the last commodity unit.

K. Menger (1840–1921) was one the first authors of the theory of marginal utility who proceeded from a personal approach to evaluation. K. Menger assessed the category of value, which is a personal judgment existing in the human mind. Labor costs are of no importance for the value. Marginal utility is seen as the utility of the last available unit of some good.

Researching the price setting of goods, K. Menger introduced the "demand price" and "supply price".

The American economist I. Fisher (1867–1947) published the work "The Purchasing Power of Money" in 1911. It gives the well-known equation of exchange: $MV = PQ$, where M is money supply; V is the speed of money circulation; P is price index; Q is the volume of transactions. For decades, I. Fisher has developed his theory of money, has published over 20 books and 170 articles, and has held many lectures. I. Fisher has dealt with the issues of money circulation of the macroeconomic level.

Representatives of the Cambridge School A. Marshall, A.S. Pigou, and D. Robinson proposed their version of the quantitative theory of money "cash balance theory", regarding monetary theory at the micro level. They assess the behavior of individuals who want to save or spend money. When analyzing the prices of goods, a professor at the University of Cambridge Alfred Marshall (1842–1924) proceeds from the ratio of supply and demand. Demand is calculated from the marginal utility of the goods for the consumer, and supply – from production costs that should be covered by the price of the goods. Thus, representatives of the Cambridge School view the price setting from the perspective of both demand and supply.

(7) Keynesian Theory of Money

J. M. Keynes put his reproductive model of the theory against neoclassical theory by A. Marshall and A. S. Pigou, since the neoclassical model initially comes from a state of supply-and-demand equilibrium under full exploitation of resources. Under the neoclassical theory, when the equilibrium under full exploitation is lost, it is restored thanks to competition and free pricing. Keynes reasons from a new reality after the First World War, where the market pricing mechanism has changed. In the economic field, there is large-scale unemployment, in industrial one—production capacities are underused, and agriculture is abandoned. Keynes explained the severe crisis by persisting shortage of effective (solvent) demand. The total savings of the population are a source of consumer and investment demand, the amount of which predetermines effective demand at the macroeconomic level.

The problem won't arise if savings are easily converted into investments, which contribute to full employment. However, if the tool of converting savings into investments is damaged, the situation entails a shortage of solvent demand and, as a consequence, an economic crisis.

Keynes explores the interest, which is a "reward for parting with liquidity" [12] and introduces a new term "marginal efficiency of capital investment", i.e. the expected rate of return on the last unit of capital invested in some business. If the marginal efficiency and the interest rate are equal, the investment process ceases, i.e. marginal efficiency of capital investments should be higher than the interest rate to prevent

crises. In these circumstances, the savings will be converted into investments. The market economy tool alone cannot provide this proportion on an ongoing basis; therefore, state intervention is needed. Keynes was the first of Western economists to reason state participation in the reproduction and the rejection of economic liberalism. Keynes offered measures of monetary policy (maintaining a low-interest rate threatening with a "liquidity trap"), as well as underfunding and creeping inflation.

(8) Monetarism

Monetarism as a modern version of the quantitative theory of money relies on the provision that the quantity of money in circulation plays a major role in economic development. The monetarism was founded by M. Friedman (1912–2006).

M. Friedman treats wealth as a combination of financial and physical assets: securities, human capital, tangible assets. Money also falls into this category. Wealth in any form can bring profit to the owner, therefore the demand for money is stable under permanent wealth pattern.

In the 1960s, a monetarist model of the cycle and national income was developed at the macro level. Studies by monetarists have shown high correlation coefficients between the trend of money supply and national income in the United States for almost a century, which evidences the monetarist provision on the leading role of money in the development of a market economy. Demand for money is a relatively stable quantity which depends on fundamental economic factors. The money supply is unstable, as far as it does not depend on the policy of the central bank issuing money.

The main conclusions made by M. Friedman are that the state as an economic regulator should only exercise control over monetary circulation. Expenses of consumers, including business, depend on the money supply in circulation. Its growth boosts production, but after some point results in higher prices and inflation. M. Friedman introduced the new term "stagflation" (the coexistence of high inflation and high unemployment). Inflation must be suppressed by any means, also by reducing the number of social programs.

Monetarism is opposed to Keynes's ideas about state intervention in the economy. In monetarist opinion, intervention entails a disturbance of natural economic development. The main factor affecting the economy is regular monetary emission since the shortage of money causes depression. Therefore, the state should continuously issue money following the growth rate of the commodity manufactured.

The principles of monetarism in practice ("Reaganomics", "Thatcherism", etc.), showed ambiguous results.

An analysis of ideas belonging to thinkers of the past on the question of wealth foundation, the tool of determining the value of goods, factors affecting the purchasing power of money, the means of estimating the money supply in circulation, shows that the theory of value and money is in direct dependence on maturity of productive forces in society and commodity exchange. Findings concerning the essence of commodity production and a market economy are relevant over the centuries.

As far back as ancient times, people pointed at the hazard of debt burden, paid attention to the ratio between profitability and risk, highlighted the production and financial sectors. Inflation as an economic phenomenon has been existing for millennia, as well as various methods to combat it.

The state as an institution interferes in the economy and finances from the time of its birth from setting denominations and values of monetary units (the nominalist concept) to state stimulation of investment demand.

The issue regarding the importance of precious metals as monetary stuff and a monetary asset (the metallic concept of money) has been studied by academic scholars and practitioners in all ages but remains open.

The importance of trade (mercantilism), including foreign one, for the welfare of the state, on the one hand, is the protection of the domestic market, but on the other hand, the relevance of this issue is growing in the context of globalization and new forms of competition for sales markets and profit.

The labor theory of value gives priority to the costs of labor performed, but marginalism is a personal factor. On the one hand, both approaches find justification in the modern image of the economy, but on the other hand, do not explain many emerging phenomena.

The quantitative theory of money going back 500 years is seeking an answer on the question of the relationship between financial and non-financial sectors, the ratio between the number of goods and money supply in circulation, the level of prices, the value of money and the standard of living. These questions exercised the minds of both mercantilists, and representatives of classical, neoclassical political economy, and bodies making decisions at the government level.

There is no clear answer since any theory cannot give all-in-one advice to ensure the best performance of the economy in a fast-changing world. The conclusions based on rigorous mathematical models gave an impetus to the application of exact sciences for an explanation of economic processes but did not show what economic laws govern the economy of the financialization era. Keynesian theory of state intervention to promote economic growth has been proved for 20 years by high growth rates but has been later replaced by monetary regulation, where state intervention is limited to control over the money supply.

But monetarism also failed in new conditions after the “Asian crisis” of 1997, the Russian default of 1998, the global crisis of 2008–2009.

The financialization of the economy, which is characterized by manifold excess of the overall global turnover of money supply and money substitutes over the turnover of goods and services, i.e. the size of the real sector serviced by money circulation means that a new stage in the historical evolution of the money theory has already come.

4 Conclusion

An analysis of evolvement of value and money theories shows the content of the category under study changes at each development stage of productive forces and production relations. The main impact on this development is exerted by concentration and centralization of capital (the territorial and economic division of the world has taken place); socialization of the economy (the part of the economy no longer functions under the law of value and market regulators); The nature of the commodity has changed (e.g. example, the occurrence of goods that don't destroy, but increase their value during consumption; or simulacra that meet the needs dictated by fashion or public opinion); financialization of the economy [13]. Here we observe a trend pointed out by the Russian economist A. Buzgalin when "money supply is determined not so much by the needs of commodity-money circulation itself, but the possible deployment of idle monetary capital to ensure its accumulation and expansion" [14]. Let us note that this concerns not only the companies but also individuals investing money in stock market instruments [15, 16].

Besides, information technologies, mechanisms and new forms of arranging production (holacracy[1]) and public (participatory budgeting[2]) activities, which were developed in the era of the digital economy, make it possible to evade mediation even in steady regulation of money regulation. We see it on the example of the creation and circulation of various types of cryptocurrencies. All these facts are indicative of the transformation of the economy into a qualitatively new state, which requires the development of value and money theory as a consequence of impersonal global changes in the world.

The Program-Oriented Management in the Public Sector: Development Tools

Mariya A. Ekaterinovskaya, Olga V. Orusova, Nelly V. Tshadadze, and Karina V. Haustova

Abstract The institute of state programs today is widely discussed not only in scientific world, but also in the practical sphere. The methodology of program target management is permanently enriched with new tools, enhancing the efficiency and effectiveness of practical application. The proposed approach of the formation of a unified contour of program-targeted management, using the institute of state programs as a constructor of socio-economic development. In general, the proposed approach can provide a systematic and comprehensive assessment that takes into account the characteristics of the development of all sectors of the economy, allowing to determine the optimal reserves for adjusting the country's development strategy. The implementation of the above measures will allow accumulating joint efforts of the federal and regional levels for the breakthrough socio-economic development of the country.

Keywords Program-oriented management · Public governance · Development tools · Socio-economic development · Modern Russia

1 Introduction

Russia was one of the first in the world to introduce a program-targeted approach. However, the transition from a command-administrative economy to a market

economy has made significant adjustments to the forms and mechanisms of tools. It should be noted the progression of the development vector of the specified tools.

We need to demonstrate a qualitative breakthrough in socio-economic development in the conditions of fierce global competition and imposed international sanctions, which can be achieved using new tools.

Focusing on world practice, we should increase the share of production costs that accelerate economic growth in the medium and long term through state programs of the Russian Federation (hereinafter—state programs), using them as a constructor of socio-economic development. This will improve the performance of the macroeconomic functions of the federal budget for the country.

Modern challenges require us to develop tools that ensure the formation of a overall contour of program-oriented management as the main element of the strategic planning system in the Russian Federation, including national (federal) projects, state programs at the federal and regional levels.

The solution of these problems will achieve the strategic goals through the concentration of limited resources at points of growth and development.

2 Methodology

The transition from "performance management" to "development management" has been beginning in public administration (Fig. 1) seems 2017. The basic principle of resource allocation in the framework of program-oriented management was revised—not "from achieved" in traditional areas of financing, and according to development priorities in terms of competition for resources.

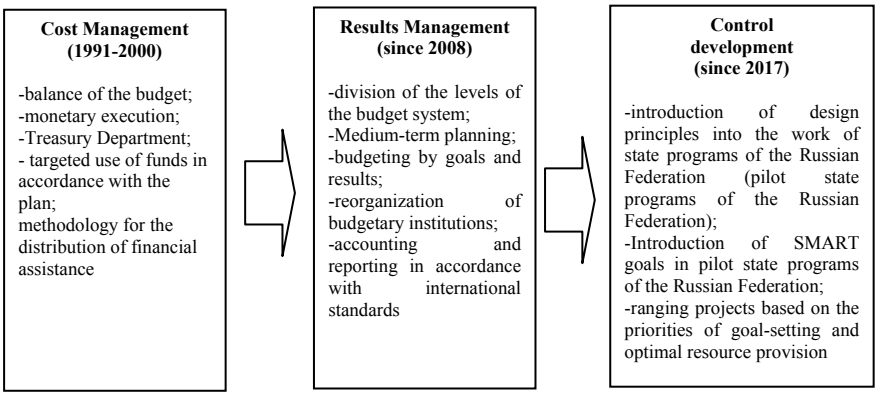

Fig. 1 Evolution of the program-targeted management methodology. *Source* Developed and compiled by the authors

Implementation of the "development management" approach, reloading of target-oriented toolkit through the project approach made it possible to focus on development, focusing on growth points.

A powerful impetus for institutional change was in improving the regulatory framework for the implementation of project approaches.

The important step was the synchronization of the process of forming the federal budget and state programs.

Since 2019, Working Groups have been formed and are working under the Government Commission on issues of optimizing and improving the efficiency of budget expenditures. They allow enhancing the potential of the institution of state programs through a constructive dialogue on the same site between the responsible executive, federal ministries, subjects of the Russian Federation, representatives of the expert scientific community [1–15].

Currently, there is a wide range of program-targeted documents (roadmaps, industrial and industrial environmental control programs, territorial and sectoral state programs at the federal, regional and municipal levels, investment programs, etc.) that are implemented in different formats.

Today, the institute of project management was updated for address initiatives at industry growth points:

- a presidential decree determines the need for the development and implementation of national (federal) projects;
- a work continues on the implementation of project management in the activities of federal executive bodies, which resulted in a transition to project management, the creation of project offices, the development of the institute of federal, regional and departmental projects, etc.

A variety of programs and projects require a unified approach to synchronizing activities in areas and industries, concentrating resources to achieve strategic goals.

Thus, the issue of developing, implementing and evaluating the effectiveness of program-targeted management documents has become much more relevant today and we are ready to constructively solve it using the accumulated experience and available potential in managerial practice.

It seems advisable to comprehensively approach the task of developing the unified contour of program-target management, among which should be highlighted:

1. Implementation of measures to integrate national (federal) projects into state programs, including the replication of the project approach to all state programs at the federal and regional levels;
2. Harmonization of sectoral and territorial management in the unified contour of program-target management by including the territorial component;
3. Implementation of measures to integrate the constituent entities of the Russian Federation and business into the unified contour;
4. Using the scenario approach in the development of state programs, using the potential of the sphere (industry) to select the best way to achieve goals in rapidly changing conditions;

5. Implementation of approaches to take into account synergetic effects in the unified contour of program-targeted management, contributing to the optimal use of limited resources, including budget, in achieving goals in state programs;
6. Approaches to the coordination of many information systems to create the unified information contour program-target management.

Such crystallization of goal setting and tools should give a positive effect in the form of a significant increase in the effectiveness of public administration.

In the current geopolitical and socio-economic conditions, the expansion of managerial tools is necessary to achieve ambitious strategic goals that provide a breakthrough of national economy.

In this regard, the Presidential Decree sets the task to develop national projects (programs) in the most important areas of state policy (hereinafter—national projects).

A national project is a set of federal projects capable of ensuring the achievement of its goals and objectives, so it is necessary to work out mechanisms for their implementation at the state level.

The main tools for achieving the Russian Federation national development goals are state programs which implement the main mechanism, joining strategic goal setting and resource potential, in which federal projects as part of national projects are being implemented.

Implementation of national projects (programs) should be carried out through inclusion them in state programs, ensuring a review of all goal setting, composition and values of indicators.

Thus, state programs are the main comprehensive tools for implementing the strategic goals of the government policy in the national economy industries.

The decomposition of the national development goals of the Russian Federation is represented by the corresponding sets of indicators contained in state programs, in which, among others, federal projects as part of national projects are implemented. These indicators are the main criteria for assessing the achievement of expected results according to the priority areas of the Government of the Russian Federation.

In order to form a unified contour of program-target management, as noted above, it is necessary to formulate common approaches to deal with state programs. In this purpose it is necessary to replicate project principles from pilot state programs to all state programs. So appropriate changes to the current regulatory framework are needed.

It should be especially noted the labor intensive way of integrating federal projects into state programs, because large-scale processing of goal setting, indicator systems, the composition of projects and activities (with a projection at the regional level), that is, a complete reformatting of state programs, will be required.

Talking about the task of integration national (federal) projects into state programs, it must be emphasized that national projects could be assigned to one or several state programs and can become a tool for analysis of the achievement of transformations in single industry or several industries simultaneously.

A similar situation is with the role of federal projects, they can be both single industry in nature and intersectoral in nature.

It is necessary to work out the criteria to determine affiliation with "federal projects", for example, the scale of transformations and the number of participants. Thus, it is necessary to distinguish the criteria for differentiation federal projects from departmental ones and, accordingly, the principles for including them in state programs.

So, federal projects should be focused on activating growth points while department projects should solve department problems. The inclusion of projects in the state program should be based on the principles of sufficiency to achieve the goals of the state program and optimality in resource provision. In this case, the state program is a "designer", and projects are "puzzles" for modeling the target state of an industry (sector).

The selection of projects in the ranking process should be worked out in terms of taking into account the significance of the projects themselves for goal setting, as well as taking into account interprogram, interproject effects, based on dynamic developing conditions and the changing potential of the industry (sector). Thus, the state program should play a role of a "designer" that easily changes the composition of "puzzles" for a particular external situation, providing the best response to the occurring scenario.

In this regard, ensuring the unity of the program-target management contour, it is necessary to provide the transfer of all state programs to the project management principles, using a unified approach to the development and implementation of state programs.

3 Results

The formation of a unified management contour, as is shown in Fig. 2, should be the main task of the new development stage of the state program institute. In order to achieve it is necessary to work out:

content and procedures for the development of the Russian Federation state programs and national (federal) projects within the framework of the budget process, taking into account the ranking mechanism. The issue of linking the development of state programs in the framework of budget processes at the federal and regional levels should also be addressed;

mechanisms for ranking goal-setting between state programs of the federal and regional level in Russian Federation. The program-target contour should be worked out in terms of the distribution of competencies between levels of authorities;

differentiated approaches to ranking indicators of state programs, federal and department projects at the regional level due to the complexity of the methodology for calculating most indicators at the federal level;

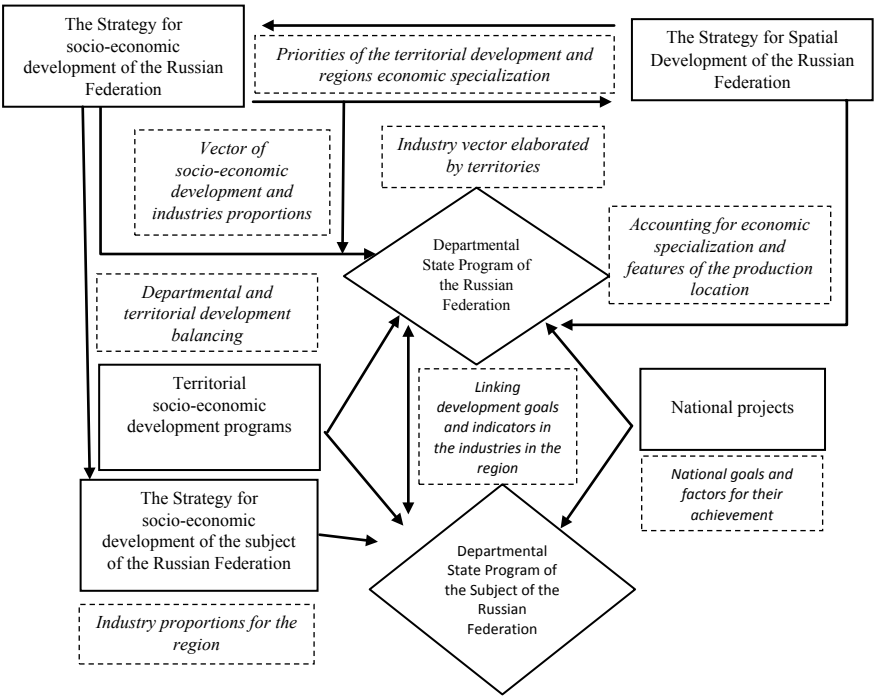

Fig. 2 A unified contour of program-target management as a part of the strategic planning. *Source* Developed and compiled by the authors

the contents and procedures for the implementation of state programs and federal (national) projects, given the need for timing and monitoring programs and projects, federal and regional levels;
the content and procedures for evaluating the effectiveness of state programs and federal (national) projects, taking into account the need to form a unified contour, including the federal and regional levels.

In order to achieve the institutional changes in the development of a unified contour of program- target management, it is necessary to create a system of end-to-end goal-setting, taking into account the upper strategic level, an end-to-end system of indicators, end-to-end monitoring and end-to-end reporting.

Using information solutions, it will be possible to assess the impact of the quarterly dynamics of the state programs implementation on the potential achievement of forecast indicators of the Russian Federation socio-economic development.

The following algorithm for implementing this approach is offered (Fig. 3).

State programs become, on the one hand, an instrument (constructor) for achieving strategic goals, and on the other hand, during monitoring, they can assess the level of approximation to the target, identifying the causes of deviations due to the different risks.

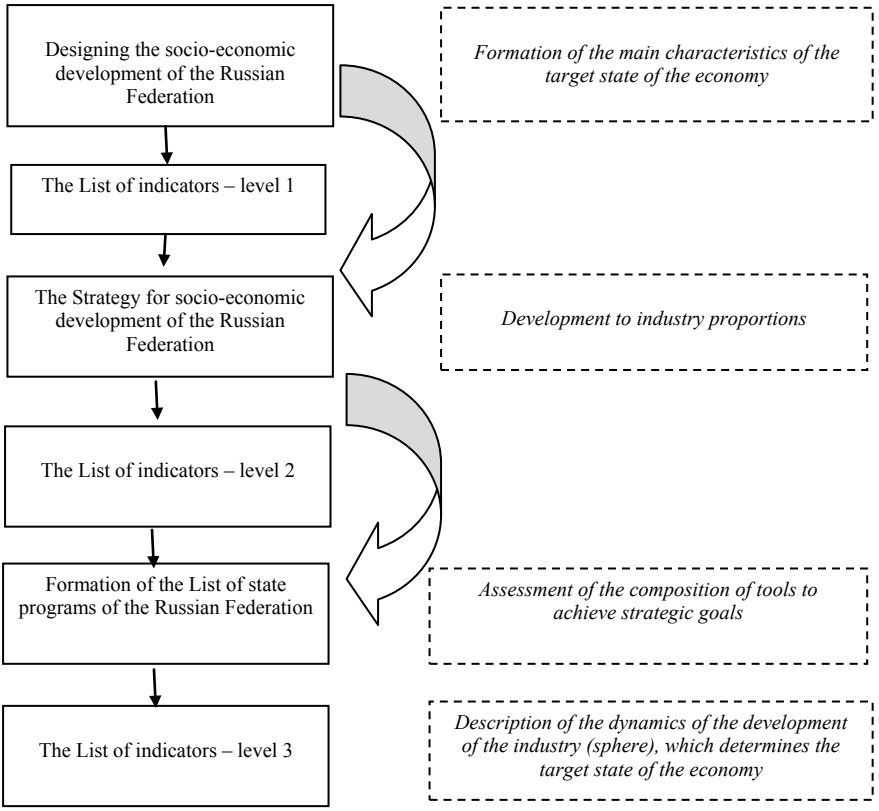

Fig. 3 State programs as a constructor of socio-economic development of Russia. *Source* Developed and compiled by the authors

Such approach will allow not only to record the results achieved and the level of costs, but also to demonstrate a structural analysis of the processes and proportions of the economy, to become the basis for improving the quality of state socio-economic policy, making the tools of a unified contour more comprehensive.

4 Conclusion

The institute of state programs today is widely discussed not only in scientific world, but also in the practical sphere. The methodology of program-target management is permanently enriched with new tools, enhancing the efficiency and effectiveness of practical application.

The proposed approach of the formation of a unified contour of program-targeted management, using the institute of state programs as a constructor of socio-economic

development, will allow not only to concentrate efforts and resources on growth points, but also:

- to conduct a structural analysis of the processes and proportions of the economic development;
- to identify reserves for improving departmental development strategies;
- to identify and range priority reserves for increasing efficiency;
- to improve the quality of the government socio-economic policy.

In general, the proposed approach can provide a systematic and comprehensive assessment that takes into account the characteristics of the development of all sectors of the economy, allowing to determine the optimal reserves for adjusting the country's development strategy.

The implementation of the above measures will allow accumulating joint efforts of the federal and regional levels for the breakthrough socio-economic development of the country.

The National Tax System at the Present Stage of Development

Irina A. Zhuravleva, Natalia V. Nazarova, Aleksandr V. Kozharinov, and Natalia V. Levoshich

Abstract The article discusses current issues of the effective functioning of the tax system, the impact of the tax burden on entrepreneurial activity. A statement of the results of the correlation and regression analysis, the relationship between the dynamics of the gross domestic product and the level of tax burden showed a linear dependence of the dynamics of GDP on the level of tax burden. The manifestation of the uneven distribution of the tax burden among payer categories suggests that the tax mechanism should be built with a focus on achieving social equilibrium in society, and for modern Russia it is the social function of taxes that is important. Proposals are being made for the direction of the tax system in order to ensure the implementation of not only direct functions (fiscal, regulatory, etc.), but also functions, for example, stimulating, aimed at the realization of public interests, the trust of the business community in the state and the implementation of the idea of justice, to reveal potential financial-economic opportunities at macro and micro levels.

1 Introduction

The tax system of the state is one of the management vectors in the structure of the country's economic system. The tax system is an integral part of the national economy, the effective functioning of which has a significant impact on its stability, especially in a recession, when the possibilities of using alternative instruments of accumulating financial resources by the state are limited. The dilemma is relevant: the influence of the tax system on the development of the economy, or institutional economy in its potential ensures the sustainable development of the tax system.

The scientific dilemma under consideration about the potential opportunity of the tax system to become more attractive for taxpayers and maximally progressive at the budget levels for the state is relevant.

It should be noted the role of the tax system in the distribution of public goods and resources that activate certain forms of socio-economic dynamics. These processes are important from the point of view of the basis for the formation of investment potential in the business environment and the formation of demand among individuals, which contributes to economic recovery and quality of life.

In order for public goods to be created, a free market is needed, which is understood as the interaction of two free and informed individuals in the form of a price exchange, which the exchange participants consider fair. This definition is quite common in the literature and in its essence no one disputes. However, if we start from this definition, the so-called market failures are not market failures, but market failure, because in each of these situations the basic principles of the market: equality of participants, free choice, equal information, voluntariness and justice are not respected and, accordingly,, these situations cannot be called market failures [14]. This situation also affects the formation of regulatory failures in taxation.

Noting the essence of the tax system as a state institution, many scientists point to the need to coordinate the priorities of its development with the strategic guidelines of the state and society, which requires the improvement of its individual elements and the system as a whole.

2 Methodology

Numerous studies of the economic situation in the country indicate that the modern tax system of Russia is a factor preventing the activation of the potential of regional economies. Since 2019 the value added tax rate was increased by two percentage points, which has already affected inflationary processes. In addition, excise taxes on excisable goods, in particular on alcohol and cigarettes, were increased by 10%. The most sensitive was the increase in fuel rates, since the movement of goods is ensured by transportation, and thus, the higher the level of excise tax and the amount of value added tax, the higher the tax burden on final consumers of goods, since these are indirect taxes and they are carried same consumer. When forming a tax policy, the

fiscal approach remains a priority, as a result of which the shadow (unobservable) economy grows.

In accordance with studies of modern tax problems of the Russian Federation, many scientists note the signs that the tax system should have—these are: structuredness, subordination to a specific goal, integrity, interconnectedness of parts, self-development. And in this regard, it is obvious that in the Russian practice of taxation there are significant imbalances between elements of the tax system, in compliance with the principles of taxation, in the mechanism of tax administration and interaction between public authorities in the field of taxes.

The reality is that at this stage in the development of the tax system in the country there is a disproportion, as a mismatch between the pace of development of parts of the system to economic realities, as a result of which the part of the overall potential of the economic system of the country and society as a whole is not needed. In addition, imbalances cause unproductive losses of capital and resources of economic systems. Moreover, any system assumes the presence of certain elements and the relationships between them, the essential guidelines of which are integrity and balance.

Imbalances in the tax system are manifested in different forms and types of inconsistencies in its composition, content and dynamics and cause uneven loads on its various elements and lead to an increase in the shadow economy and tax evasion. Such a situation aggravates the separation of tax accounting from accounting, although there is a tendency to bring them closer together in the country [12].

Factors causing inconsistencies in the tax system impede the legitimate flow of tax revenues to budgets of various levels and make the strategic goals of developing the economy of the state and society impossible. Such conditions include: variability of tax legislation, uneven distribution of tax burden, inefficiency of the tax administration mechanism, inefficiency of tax benefits, etc.

It cannot be said unequivocally that a system of maximum taxes is inherent in modern Russia, the result of which may be such that when the increase in the tax burden is not accompanied by an adequate increase in state revenues, transformations of property and government institutions and the formation of a tax mechanism focused on economic growth and solving social problems are necessary and reorienting fiscal function to stimulating. According to many scholars, the fiscal-oriented tax system in Russia has acquired a confiscatory nature, the regulatory function is poorly performed, and the stimulating one is manifested in terms of providing tax preferences for taxation of a number of services, activities, business scale, etc. at different budget levels.

From the position of creating an optimal development trajectory and the urgent need to transform the goals of the tax system of Russia in line with the idea of the independence of territorial entities and minimize the redistribution of financial resources, we pay attention to the imbalances in the tax system, which are studied in numerous scientific and practical works of recent years. There is a dependence of the dynamics of the national economy on the level of tax burden. A well-known factor is that an increase in the tax burden leads to a drop in GDP growth rates and vice versa. Reducing the tax burden, in their opinion, has a positive impact on business activity, contributes to increased investment activity. The data presented in Table 1 reflect the

Table 1 Indicators of the dynamics of the level of tax burden in Russia and the Gross Domestic Product of the Russian Federation in 2011–2017

Indicator	2011	2012	2013	2014	2015	2016	2017
Tax burden,% of GDP	34.50	32.49	31.80	31.89	32.3	31.1	30.8
Dynamics of GDP at current prices, %	4.3	3.7	1.8	0.7	−2.8	−0.2	1.5
Tax revenues of the consolidated budget of the Russian Federation, billion rubles	9,715.2	10,954	11,321.6	12,606.4	13,720.1	14,386.3	17,197.2

level of tax burden in Russia for the period 2010–2017, which ranges from 30.8 to 34.50%. At the same time, an analysis of the level of tax burden on the economy carried out for the BRICS countries and the Eurasian Economic Union shows that this indicator in relation to Russia (according to the International Monetary Fund) mainly significantly exceeds the BRICS countries and the Eurasian Economic Union for the period 2010–2017 ranges from 34.62 to 37.69%.

The table is compiled according to the Ministry of Finance of the Russian Federation.

It should be noted that the country's tax system also includes the principles of the establishment, introduction and termination of local and regional taxes; the grounds and rules for the occurrence, change and termination of the duties of certain persons to pay taxes and fees, as well as the procedure for the performance of these duties; rights and obligations of participants in relations arising in the taxation system (taxpayers, tax authorities, etc.); liability for violation of tax laws; forms, types and methods of monitoring compliance with tax legislation; information subsystem of the tax system (notices, tax service website, etc.).

In order to improve the tax system, one of the authors of this article, I. A. Zhuravleva, proposed in earlier published scientific papers "to consider the development of the tax system and its elements based on a systematic approach, namely the"Periodic System of Special Laws of Nalogonomy"(hereinafter—PS SLN), compiled and discovering by Associate Professor I. A. Zhuravleva in 2017 [5, 7, 12, 15].

Nalogonomy is a scientific system that studies the self-organizing structural and functional composition of primary elements of taxation in order to create, develop and evolve a country's tax system [6, 8, 9, 13]. It should be noted that, in fact, in PS SLN, the author uses the Systemonomic Approach and Method, because the tax system is the brainchild of a Systemonomy. "The Periodic System of Special Laws of Nalogonomy", compiled on the basis of the "Periodic System of Universal Laws of the World", opened by academician N. V. Maslova in 2005 [4].

"The Periodic System of Universal Laws of the World", being a single interconnected system and manifests itself in all phenomena, systems of the World: economic, social, scientific, financial, educational, legal and others, is projected onto society, a person and the processes of cognition, thinking are shown evolutionary path of development according to the levels of being and the group of laws. "Systemonomy is a scientific tool for motivating the cosmic spiritual worldview of mankind. Systemonomy is the next evolutionary step in understanding the World system" (Maslova, 2005).

At this stage of reforming the tax system, there is a tendency that the system is improving itself more in terms of tax administration, but not in terms of changing types of taxes, reforming tax bases, other elements of taxes or the system as a whole. There is no systematic approach to the achievement by the tax system of its highest socio-economic, scientific, legal, financial, cultural potential. "The highest potential of the system is the integrated sum of all the capabilities of the system aimed at maximizing its self-disclosure and self-realization in achieving its mission" [3].

The "Periodic System of Special Laws of Nalogonomy" is compiled on the basis of the "Periodic System of Universal Laws of the World", opened by academician N.V. Maslova in 2005 [13]. The Periodic System of the Universal Laws of the World, being a single interconnected system and is manifested in all phenomena, systems of the World: economic, social, scientific, financial, educational, legal and others, is projected onto society, a person and processes of cognition, thinking, the evolutionary path of development is shown according to the levels being and a group of laws.

There are two system analyzes to consider the identified problem:

> The first is a systemological approach, which implies an analysis of the presence of all the constituent parts of the system, and in particular the tax system, and these are: its goals, elements, unity of connections between elements and composition. The second (the author Zhuravleva I.A. proposes to consider it) is a systematic one, including the Universal laws of the World, the General laws of cognition and comprehension of the World, the General laws of human society, the goal (the program of the purpose of the functioning of the system), elements of the system, the unity of connections between elements of the system and system composition. The modern tax system is based on the first system analysis [2].

The motivation of the author's proposal for the use of PS SLN is that, for the above reason, we cannot judge the quality of the evolution of the tax system in nature and society, in the worldview and socio-economic and financial orientation [11]. This is the reason that does not allow the modern tax system to build harmonious relations between the state and taxpayers, the business community. The goal vector is not aimed at constructive comprehension of the Universal Laws of the World, human society, knowledge/comprehension. Therefore, in the most general understanding of this situation, the existing tax system focuses only on fiscal policy, on the fragmentation of knowledge about the World, economic processes and financial flows, there is no single core in the state that has a creative-creative direction vector. Shifting the tax burden on the final consumer, citizens of the state, raising the basic VAT rate from 18 to 20%, introducing a tax on the self-employed population (according to

the Federal State Statistics Service in the informal sector, there were 15.4 million people, which is 21.2% of the total number of employed citizens) [13], an increase in the tax base on property taxes for individuals (cadastral value of land, property) and a number of other economically unjustified fiscal measures lead to the formation of serious imbalance in the country's economy: the profitability of citizens will decrease, the purchasing power of the population will decrease, the number of unemployed will increase, social stratification will increase, social insecurity will increase, and business confidence in the existing system of both public administration and tax will decrease.

The tax system also includes the principles of the establishment, introduction and termination of local and regional taxes; the grounds and rules for the emergence, change and termination of the duties of certain persons to pay taxes and fees, as well as the procedure for the performance of these duties; rights and obligations of participants in relations arising in the taxation system (taxpayers, tax authorities, etc.); liability for violation of tax laws; forms, types and methods of monitoring compliance with tax legislation; information subsystem of the tax system (notices, tax service website, etc.) [1].

In many scientific works, modern economists emphasize the fact that in countries with developed economies, direct taxes (individual income tax, corporate income tax) are given a great emphasis in the collection of taxes. At the same time, the issue of indirect taxation is in the first place for developing countries [10, 12]. In this regard, it should be noted that it was with VAT that the trend began to improve the quality of administration and increase the tax burden. The introduction of a counterparty control system through the use of ASK VAT-3 showed a positive result out of 1600 one-day firms for two years, 130 remained.

It should be noted that in the digital economy, the nature of the competition for entering the production and consumption market is fundamentally changing. The development of information technologies leads to the fact that companies are forced to act in a format of "compression" of time and space [6, 8, 9, 13]. In this regard, new information technologies that simplify administration procedures allow the business community to reduce the tax burden on business processes.

3 Results

A comparative analysis of the dynamics of the level of tax burden in Russia, GDP and tax revenues of the consolidated budget of the Russian Federation in 2011–2017 was carried out taking into account the fact that the formation of tax revenues of the consolidated budget of the Russian Federation and GDP takes place in a specific institutional environment and the factor determining their volume and dynamics is level of tax burden on the economy.

The correlation and regression analysis carried out by the author, the relationship between the dynamics of the gross domestic product and the level of tax burden showed that the regression equation obtained from this sample characterizes the

linear dependence of GDP dynamics on the level of tax burden. At the same time, an increase of the latter by 1% leads to an increase in GDP by an average of 0.6%. The value of the correlation coefficient $r_{xy} = 0.3$ indicates that the level of tax burden does not significantly affect the dynamics of the gross domestic product and the tightness of the relationship between them is defined as weak. The quality indicator of the regression equation $R^2 = 0.077$ says that only in 7.8% of cases changes in the level of tax burden lead to a change in the dynamics of GDP. The remaining 92.2% of the change in the dynamics of GDP is explained by factors not taken into account in the model.

The results obtained reflect the problem of an objective assessment of the real tax burden. The peculiarity of the modern Russian tax system is that there are many payments in it that are similar in their economic nature to taxes, but not related to those under tax law. As a result, the real tax burden is an order of magnitude higher than the indicator declared by official statistics. In addition, the level of tax burden is determined by different methods, which has corresponding consequences for an objective assessment of its impact on socially significant indicators.

The results of the correlation and regression analysis should also be linked with the periods of the financial crisis, the price conditions for the formation of GDP, the level of tax administration, etc. Thus, the modern tax system is focused on price increases, and therefore, there is an increase in tax revenues and the illusion of an increase in budget revenues, although, in fact, the inflation factor works. Although there is an increase in tax resources, but at the same time the budget deficit is increasing due to an increase in costs that are subject to inflation to a greater extent.

Correlation-regression analysis of the relationship between the dynamics of tax revenues of the consolidated budget of the Russian Federation and the level of tax burden for the period 2011–2017 showed that there is a linear inverse correlation between the level of the tax burden and tax revenues of the consolidated budget of the Russian Federation, and an increase in the tax burden of 1% leads to a decrease in tax revenues of the consolidated budget of the Russian Federation by 1,056.7 billion rubles. The value of the correlation coefficient $r_{xy} = -0.42$ indicates that the level of tax burden affects the volume of tax revenues of the consolidated budget of the Russian Federation and the relationship between them is defined as reverse and moderate. The quality indicator of the regression equation $R^2 = 0.176$ says that in 17.58% of cases, changes in the level of tax burden lead to a change in the volume of tax revenues of the consolidated budget of the Russian Federation. The remaining 82.42% of the change in the volume of tax revenues of the consolidated budget of the Russian Federation is explained by factors not taken into account in the model, and indicate the complex structure and mechanism for generating tax revenues of the consolidated budget of the Russian Federation.

The next drawback of the tax system of the Russian Federation, which needs to be improved, is the manifestation of the uneven distribution of the tax burden among payer categories. The tax mechanism should be built with a focus on achieving social equilibrium in society, and for modern Russia it is the social function of taxes that is important [12]. Coordination of requests from different social strata of society is

Table 2 Distribution of the tax burden on personal income tax between different groups of citizens in the context of individual countries (%)

Country	Share of taxes paid by 1% of the least wealthy taxpayers	Share of taxes paid by 10% of the least wealthy taxpayers	The share of taxes paid by 50% of the least wealthy taxpayers	Share of taxes paid by 1% of the richest taxpayers
Russia	0.1	1.7	21.4	5.1
USA	0.0	0.1	8.2	34.0
Great Britain	0.0	0.6	11.2	26.5

Compiled by the authors

associated with the provision of a certain optimal combination of their interests and income balance.

The idea of justice is especially important for Russian society, but in the 90s this system collapsed. At present, this is a system consisting of two main subsystems: a subsystem of socially significant public goods provided by the state (reproduced through the mechanism of the tax system) and, separately, the tax system should carry elements of justice within itself.

Analysis of the data on the distribution of the tax burden on personal income tax between different groups of citizens by individual countries yielded the following results, shown in Table 2.

4 Conclusions

The existing problems of increasing the tax burden, the predominance of fiscal interests of the state over stimulating the development of modern, priority sectoral and socially significant areas in the country's economy exacerbate the situation in terms of the desire to conceal income by individuals, small and medium-sized enterprises, splitting up large businesses, and withdrawing capital from the country.

The tax system should ensure the implementation of not only direct functions (fiscal, regulatory, etc.), but also functions, for example, stimulating, aimed at realizing public interests, such as uniting society, trusting the business community in the state and implementing the idea of justice, and disclosing potential financial and economic opportunities at macro and micro levels. The tax system should be focused on creating a mechanism to solve the problems of economic development, attracting investments, improving the social and cultural standard of living of people, and other tasks, possibly interstate, foreign policy, to facilitate the integration of economies of different countries of the world.

Determination of the Infrastructure Industry Optimal Parameters by Means of Mathematical Modeling

Mikhail I. Kuternin and Elena A. Gubareva

Abstract This paper is dedicated to the study of the efficiency of various infrastructure industry flowcharts. The article develops a method of estimating the favorable values of vertical industry integration and prices at the network enterprise, which is the natural monopoly core of the industry. The basic research method is a mathematical simulation. We designed a mathematical model of the industry based on production costs functions. We have found out that the solution to the problem of the favorable infrastructure industry implies the elaboration of a state strategy for industry development. The paper reviews the strategy of ensuring the highest output of the industry while maintaining the possibility of sustainable development through internal reserves. The authors have revealed that such a strategy requires industry to be arranged in view of vertical integration with the competition. The article identified an economically sound level of industry integration. The methodology of the paper can be used in estimating the favorable parameters of infrastructure sector development, and the model designed – parameters of price regulation of network facilities.

1 Introduction

In the economy of any country, infrastructure industries play an important role in providing the performance of each enterprise. Due to the crucial importance of these industries, which often play a system-forming role, the government even in market-economy countries is seeking to control them to some extent, while keeping their integration at a high level. With that, a single highly integrated body under state control inevitably turns into a market monopoly, which results in lower performance. In this regard, one faces an acute problem to estimate the favorable integration of the infrastructure industry, which would allow for taking advantage of a competitive economy, thereby granting their particular system-forming role.

This problem is getting more complicated because the core of infrastructure industries is usually network enterprises that own through-passages, product pipelines of various nature, power supply lines, etc. The activities of such enterprises have a pronounced effect of economies of scale, as well as other specific features [1], which make their partition into several competing enterprises unprofitable and assign to them the status of a natural monopoly.

As a result, over the past two decades in the Russian economy there have been two opposite trends of arranging infrastructure industries, which can roughly be called liberal and dirigiste. The simultaneous existence of two opposite trends has led to the emergence in modern Russia of infrastructure industries as production associations with different levels of integration [2].

An example of an infrastructure industry designed under a full vertical separation flowchart is the electric power industry of the Russian economy. Total state control is here over the Federal Grid Company, which is a network enterprise representing the natural-monopoly core of the power industry and owning backbone transmission lines.

In turn, an example of a single highly integrated vertical body is Gazprom OAO, which covers a large portion of the entire gas industry. Gazprom is a dominant company involving a great number of all gas producing companies in the country, as well as almost the entire gas pipeline network, which delivers natural gas to the end consumer and. It's a natural monopoly by its technical and economic features.

Nowadays, amid the deterioration of international relations, the construction of the gas pipeline "Nord Stream-2" again raises the question of the favorable integration of the infrastructure industry. The third energy package, which is part of the EU legislation on the relaxation of gas and electric power markets, requires the monopoly of gas and electricity suppliers to be limited to prevent possible cancellation of competing companies' supplies through ownership of consumer distribution networks. According to the requirements of the Third Energy Package, the owner of the grid company must hold at least half of the capacities for the delivery of third-party products. This approach to the arrangement of product delivery is efficient due to taking advantage of a competitive economy.

After all, using the mathematical model of the infrastructure industry, we should establish the extent of separation of manufacturing enterprises (i.e., gas producing

companies—in gas industry) and owners of backbone networks (for example, a gas transmission system) under which there will be possible to take advantages of a competitive economy and enhance the performance of the industry. Therewith, required state control over the network enterprise acting as the natural monopoly core of the industry needs competent economically sound state regulation of its activity. The main problem here is accurately set the price for services of network companies on delivery of the commodity of independent producers to consumers. This price, on the one hand, should ensure the growth of the entire industry and take into account the interests of producers and consumers, but on the other hand, it should provide an opportunity to invest in the network facility itself through correct estimation of its profit rate.

2 Materials and Method

The problems regarding the performance of highly integrated vertical associations were mentioned in foreign economic literature at the close of the last century. The structural deficiencies of such associations were reviewed and the urgency of their reform pursued at that time was substantiated [3]. Some works have identified possible infrastructure sector design flowcharts, besides the challenges of gas field integration have always stirred up the hottest debate [4]. At the same time, Russian scholars presented a detailed retrospective analysis of various approaches to the governance of natural monopolies [5].

Since then, infrastructure industries in many countries, including Russia, have undergone the reform, therefore, until recently, many authors carried out an analysis of occurring changes. Moreover, both domestic (for example, [6]) and foreign authors [7]) usually make a high-quality comparison of various industry design flowcharts. A while back Deryabina conducted one of the most in-depth analyses of available flowcharts [2]. However, the question of a quantitative comparison of industry design flowchart indicators is raised rarely. Perhaps the most advanced quantitative analysis of flowcharts using the example of the railway transport of the Russian Federation was given by Dement'ev and Khakimov [8]. The authors developed a model of a vertically integrated body and compared the consumer's overflow under various flowcharts. But the problem of quantitative measurement favorable integration values and other parameters of the industry has not been brought up. This problem we'll try to solve in the paper with the help of mathematical simulation.

3 Findings

This article develops a technique of estimating the favorable values of two industry design parameters established by the government. Firstly, we are making a numerical evaluation of various design flowcharts' performance depending on the rate of

integration and calculating its favorable level. Secondly, we are computing the parameters of price regulation of the network core, which can ensure both its development and performance of the industry as a whole. The technique has been developed using a mathematical simulation of the industry. This technique should be acceptable for the study of any infrastructure industry, therefore, a typical flowchart of the model infrastructure industry is used when describing the algorithms for evaluation of the favorable parameters. However, for making quantitative implications we have employed the numerical values of some indicators (average costs, demand functions) similar to common ones to the gas industry of the Russian Federation in 2013, which allows us to assess the appropriate structure of this industry in quantitative terms.

Let's examine the infrastructure industry flowchart (Fig. 1). For an industry with full vertical integration, this kind of flowchart was presented in the article by Kuternin [9]. The infrastructure industry consists of three blocks: manufacturing enterprises (block I), a network enterprise (block II) and consumers (block III). The first block is constituted by producing or manufacturing enterprises. They use the services of

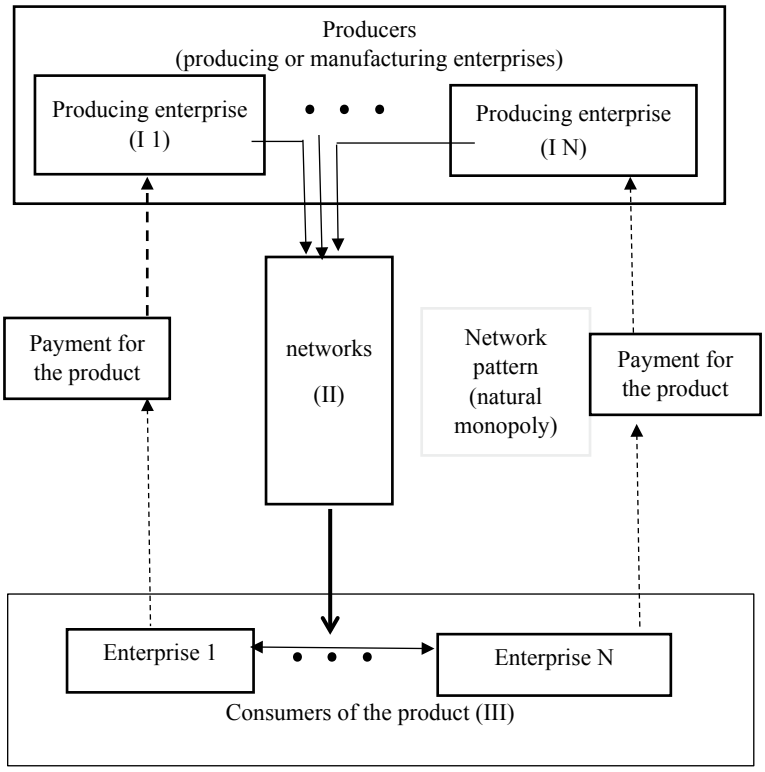

Fig. 1 The flowchart of the infrastructure industry [developed by the authors on the back of research data]

network facilities (for example, rail transport or communication services) for product distribution to consumers.

The second block is represented by a network enterprise, which is a specific feature of the infrastructure. These are product lines of various nature (for example, a gas pipeline network) or backbone transmission lines, a railway network, etc. Network enterprise by its technical and economic features is a natural monopoly. Block III unites any consumers of products transmitted through the network facilities.

Contingent on the integration level in the most important infrastructure sectors, all manufacturing enterprises or some of them can be merged into network enterprise.

It's also possible to merge the enterprises engaged in sales. It's highly important to decide what manufacturing enterprises can be integrated into one business unit under common control with the network enterprise. Here, there is a choice from full vertical integration (like Gazprom) to a full vertical separation (like in the electric power industry of the Russian Federation). Perhaps the most reasonable choice will be vertical integration with a partial separation of manufacturing enterprises, as required by the least strict version of the Third Energy Package. Such a flowchart is called vertical integration with the competition.

Let's simulate a mathematical model of the infrastructure industry, as shown in Fig. 1. As a basis, we've decided to use the parameters that play a critical role in the internal arrangement of industry integration and, consequently, have an impact on the effectiveness of integration.

A key point estimating the profile of the economic performances of the infrastructure industry and distinguishing it from other industries is two constituent parts with a quite different pattern of production costs.

Therefore, current models of other industries cannot be applied to the description of the industry. The paper is primarily aimed at estimating the rate of organizational integration of these two constituent parts. In this connection, we've agreed on simulation of a mathematical model using a production cost functions.

Let's start with a review of the full vertical separation case when all the enterprises of the first block are independent. A typical model of industry flowchart used in the developed technique implies that N of manufacturing (or producing) enterprises have the same parameters. The average production costs of each enterprise involved in the block I of the flowchart have a U- dependence on the output [10]. The dependence is expressed by a square trinomial:

$$AC_{1i} = aQ_i^2 - bQ_i + c \quad (i = 1, 2, \ldots, N), \tag{1}$$

where AC_{1i} is the average cost of the enterprise; Q_i is the number of goods manufactured by i-enterprise.

The network structure (block II) of the given flowchart is the natural-monopoly core of the industry and acts as a separate enterprise under vertical separation flowchart. The average costs of any natural monopoly decrease as production output grows in the entire range of possible output [10]. This dependence is expressed by a rational function and presented as hyperbola (2):

$$AC_2 = \frac{k}{Q} + l, \tag{2}$$

where AC_2 is the average production costs of a network enterprise; Q is the production output. In the event of no loss, it is the same as the total output of all manufacturing enterprises:

$$Q = \sum_{j=1}^{N} Q_j. \tag{3}$$

The price of product distribution through networks is fixed by the natural monopoly enterprise with regard to its expenses and in view of its development strategy. The interests of economic development always make the state to keep control over the natural monopoly, and price regulation of the natural monopoly market is an essential element of state regulation of the economy [11]. Let's denote the production unit transportation cost. Manufacturers pay this cost to the network enterprise.

The consumer sector (block III of the flowchart) is characterized by a demand function, which we regard to be a decreasing linear dependence:

$$p = m - dQ, \tag{4}$$

where p is the cost of the product (cost of the production unit for the consumer).

The profit of the competitive sector enterprises is calculated from the sales revenue, taking into account transportation and production costs, by formula (1):

$$\pi_i(Q_i) = pQ_i - AC_{1i} \cdot Q_i - p_0 Q_i = pQ_i - (aQ_i^2 - bQ_i + c + p_0)Q_i. \tag{5}$$

The cost of product p is estimated by the demand function (4) proceeding from the production output (formula 3). Now, from Eqs. (3)–(5), bearing in mind the assumption on the equality of manufacturing enterprises parameters, we have the profit of these enterprises:

$$\pi_i(Q_i) = (m - aQ_i^2 + (b - dN)Q_i - c - p_0)Q_i \quad (i = 1, 2, \ldots, N) \tag{6}$$

Under a fixed transportation cost p_0, this dependence looks like a cubic polynomial from the output of the manufacturing enterprise. Equalities (1)–(6) are a mathematical model of the infrastructure industry presented in Fig. 1. Since the paper is aimed at estimating the most suitable framework of the gas industry in the Russian Federation (especially in reference to the Third Energy Package of the UES), the numerical values of factors in formulas (1)–(6) were selected in such a way so that the dependencies described by formulas (1), (2) and (4) would be common to this industry. After calculations performed, we obtained the following factors:

$$a = 1; \quad b = 10; \quad c = 50; \quad k = 5000; \quad l = 10;$$
$$m = 120; \quad d = 0.12; \quad N = 100 \tag{7}$$

Using the given model, we computed the favorable values of industry design parameters. As far as the network enterprise is a natural monopoly governed by the state, the value p_0 is established according to state price regulation of the market in the industry under consideration in view of the development strategy of this market and the natural-monopoly network structure. The most suitable structure of an industry can be designed after the specific policy of its price regulation will be examined.

At the first stage, we examined the simplest strategy of natural monopoly governance under the simple reproduction pattern with zero profit. With that, the enterprises of the competitive sector (block I), on the contrary, are seeking to get the highest possible profit.

Using differential calculation methods, we found the favorable values of output (in nominal units) and profit (in nominal monetary units) of each enterprise in the competitive sector, as well as profit margin (as a percent to production costs), the market price for the unit of production, the transportation cost of the production unit and the total volume of industry output under the most favorable (in terms of profit maximization) output of manufacturing enterprises:

$$Q_{i1}^* = 3.85; \quad \pi_{i1}^* = 94,3; \quad R_{i1}^* = 93\%; \quad p_1^* = 73,8; \quad p_{01}^* = 23 \quad Q_1^* = 385 \tag{8}$$

As can be seen, the strategy of simple reproduction in the natural-monopoly core of the industry can provide a very high-profit margin for manufacturers. However, such a strategy can entail the downfall of networks, and, in turn, the entire industry, and should be used only as a measure of anti-crisis regulation of the industry.

Further, we studied a more common case when the state sets the profit margin of a network enterprise equal to v. Relying on the model (1)–(6), we obtained through the analytical method the dependence of the industry output decline on the profit margin of the network body. So, for example, if $v = 0.38$, which corresponds to profit margin of Gazprom OAO in 2013, favorable industry indicators that are similar to ones given in Eqs. (8) for simple network reproduction strategy can be written as follows:

$$Q_{i2}^* = 3.71; \quad \pi_{i2}^* = 61; \quad R_{i2}^* = 61.7\%; \quad p_2^* = 75.5; \quad p_{02}^* = 32.4 \quad Q_2^* = 371 \tag{9}$$

As can be seen from the above figures, for a full vertical separation flowchart a slight (3.6%) decrease in total output and a slight (2.3%) rise in the final price of products allow for the augmentation of network profit margin from zero to maximum in recent years.

From the above considerations, it follows that after analysis of the industry state of it is possible to eliminate the current structural imbalances by setting a particular margin of profit for the network enterprise. When transition processes will be

completed and structural imbalances will be removed one can turn to commensurate development of all industry constituents to make the profit margin of the first two blocks equal. Such development enables flexible management using various funding sources towards investment attractive framework of the industry.

Studies have shown that commensurate development of the entire industry can be reached through the 5% decline of the total output against the maximum one using the strategy of simple reproduction. This finding is applicable to the industry designed under vertical integration—competition flowchart. The main problem in this industry is to estimate the favorable rate of integration.

Let's look again at the flowchart of the infrastructure industry (Fig. 1). Here, the competitive sector of manufacturing enterprises (block I) consists of N enterprises. In an industry designed under vertical integration-competition flowchart, some enterprises are integrated into a single production association with a network enterprise. This association is governed by the state. Let's suppose that in the flowchart presented in Fig. 1 n of enterprises constitutes a single body with networks. This body is the public sector. The rate of industry integration is defined by the formula:

$$RI = n/N \cdot 100\%. \tag{10}$$

The paper reviews one of the most widely used types of state industrial policy, i.e. minimization of average production costs under a fixed profit of the public sector established by government bodies. Under these assumptions, total output has become a function of the industry's integration rate. Getting the highest possible output will help to reach the desired rate of integration.

For the example typical for the gas industry of the Russian Federation we gained the following results. When the integration rate ascends from zero value, the total output slightly increases in a certain interval. This happens because for state-owned manufacturing enterprises the output is fixed at the rate of the minimum average costs. The profit of enterprises in the competitive sector is starting to slightly decline (at a rate which is 1.5 times higher than the total output growth). The required rate of industry integration RI^*, in this case, is approximately equal to 21%. The total output rises by 3–4% against full vertical separation flowchart. The best parameters of industry design are given in the following equations:

$$\begin{aligned} &Q^*_{i3} = 3.47; \quad Q^*_{j3} = 5; \quad R^*_{i3} = 46.5; \quad R^*_{j3} = 50.5; \\ &p^*_3 = 74.5; \quad p^*_{03} = 34.4; \quad Q^*_3 = 379; \quad RI^* = 21\% \end{aligned} \tag{11}$$

Equations (11) indicate the output of enterprises in the competitive and public sectors, profit margins in both sectors, the price for the end product, network distribution cost, the total output, and the desired rate of industry integration. Thus, the sustainable development of the industry is maintained by internal reserves.

If integration keeps on growing, the profit of the competitive sector is increasingly falling and the total output of the industry is dropping too. Finally, under 50% integration of the industry, the competitive sector loses profit and it is driven out

of the market. Thus, we get a full vertical integration flowchart. But to maintain a high-profit margin it required to artificially decrease production output. Thus, in terms of the numerical example under consideration, the favorable rate of integration is 20–22%. When choosing a strategy to keep the equal values of the profit margin in public and competitive sectors, the most suitable flowchart is the one with full vertical separation. The output of the industry is lower by several percent, and the price for the end product is higher.

The algorithm presented in the paper is a technique for estimating the favorable parameters of the infrastructure industry. For this technique to be pursued, the government should work out a strategy for the development of the industry, which is contingent on the economic and political situation in the country. Ultimately, from the economic perspective, the strategy reveals the relationship between the urgency for industry input maximization and the need for its consistent development.

4 Conclusion

The paper offers a technique to estimate the critical parameters for infrastructure industry design, which depend on the development strategy adopted. The main development strategy examined in this paper is ensuring the highest possible output while maintaining sustainable development through internal reserves. Such a strategy results in a vertical integration-competition flowchart and brings the highest growth rates of the industry. The early achievement of the highest output indicators leads to full vertical integration flowchart and urgency for considerable state investment in the industry development. Providing the commensurate development of all constituent parts is possible under full vertical separation flowchart. The government role here is reduced to flexible price regulation of the natural monopoly, which ensures commensurate development of all industry constituent parts.

Summarizing the results of the study, we have drawn up the following conclusions:

(1) The problem of infrastructure sector flowchart improvement can be solved provided that the state will work out the strategy for its development involving the goals of the industry regulation (getting the highest possible growth rates, enhancing investment attractiveness, removing structural imbalances, etc.).
(2) The specific nature of the infrastructure industry is contingent on its constituent parts with much different patterns of production costs. We've simulated a mathematical model of the industry using the production cost functions.
(3) The favorable values of state-regulated industry parameters can be calculated through the method of mathematical simulation using the suggested industry model. The parameters of this model should be estimated by econometric methods.

(4) Ensuring the highest industry output while maintaining sustainable development through internal reserves requires is feasible under vertical integration-competition flowchart. The rate of integration can be estimated by the technique recommended by the authors.
(5) The economically sound level of integration for the designed industry model with parameters similar to ones of the gas industry in the Russian Federation is slightly over 20%.

The Application of Information Systems When Conducting Genomic Research

Andrey A. Inyushkin, Elena S. Kryukova, Yuriy S. Povarov, Valentina D. Ruzanova, and Tatyana I. Khmeleva

Abstract **The purpose of the article** is to reveal the peculiar features of information systems' application in genomic research, including the circadian genetics topic, and to establish the relationship and consistency of general and special rules in this regard. **The main approaches** to the study of the above problem are interdisciplinary, systemic and dialectical. These approaches allow estimating the application of information systems in genomic research from the perspective of the general terms "information contained in the database" and "information technology". **Findings**: it has been found out that genomic research should be closely related to the application of state information systems. The authors have suggested developing leverages for the communication of various structural and other units of the field (system) within which this application is allowed by law and to advance the legal conceptual framework for differentiation of the legal status of parties depending on the application of databases when dealing with genomic information. Also, the authors have determined the need for bringing the regime of information technologies and databases related to the genomic research into line with the common rules on any information databases, on the one hand, and separation from cases of genomic information exchange out of their scope, on the other hand. The prospects of using blockchain technology research for fixing circadian gene research findings have been positively

1 Introduction

Nowadays, means of acquisition, processing, and application of information resources, also through information systems, are constantly emerging (updating). The development of information technology enables society to use a larger volume of information, which makes the problem of information security topical [1–4]. Almost annually a variety of new information systems emerge in Russian laws, which inevitably entails an urgent need to develop a legal regime that would, on the one hand, provide the consistency of approaches to their performance, and on the other hand, enable the regard of peculiar application of information resources in individual segments of activity. Today, there is an extensive regulatory pool that establishes the procedure for the development, adaptation, and operation of information systems, which should be further refined, since legal regulation in the context of the transition to the information society has become increasingly important. As the theory rightly stresses, the current level of regulatory provision of the information society in Russia cannot yet be recognized sufficient [5] and appropriate.

Current Russian law contains both common regulations applicable to all information systems and special rules regarding some information systems [6]. Pursuant to Article 2 of the Federal Law No. 149-FZ as of July 27, 2006 "On Information, Information Technologies and the Protection of Information" (hereinafter—the Law on Information), an information system is understood as a collection of information contained in databases and information technologies and hardware for its processing. From the above definition follows that the lawmaker interprets any information system as a combination of several interrelated elements, i.e. information, information technologies and hardware [7]. In turn, the Civil Code of the Russian Federation stipulates inextricable connection of the database with a computing machine as a prerequisite for its existence (Par. 2, Cl. 2, Art. 1260). As we can see, the legal definition of an information system is based on the theory of systems, which describes the system as an ideal object acting as a set of elements. The vast majority of authors whom we agree with (relying on the ideas of the general system theory founder L.

von Bertalanffy) that essential features of a system are multiple elements and connections (relations, interactions) (it's commonly known that L. von Bertalanffy defines the system as a combination of interacting elements [8]).

The current importance of genomic research, which should be supported and partly controlled by the government, has greatly increased since the findings can have both positive and negative effects on the state of society (in ensuring the health of the nation, respecting for constitutional rights of residents, etc.). In this context, there has been a need to document this kind of research findings through databases. We believe that genomic research should be closely connected with state information systems that have distinctive features explained, among other things, by a special regulatory framework developed for them [1–4].

Genomic research today is a key area of digital economic development. In this regard, finding the best ways of introducing the results of intellectual activity regarding genomic research into civil relations is a priority task for the development of the country's economic base [9]. This problem cannot be solved without the application of information systems in genomic research.

2 Materials and Method

Developments in the general theory of systems were carried out by von Bertalanffy [8]. The current state of laws fixing the legal regime of information systems was assessed by Bejtlich [4], Amelin [1–4], Gritsenko and Shcherbinina [5], Kryukova and Ruzanova [6]. Inyushkin [7, 10, 11], Chang and Zhu [12] addressed in their works the issues of databases and intellectual property.

Interdisciplinary peculiarities of genomic research, including circadian genetics, as well as problems of genomic registration, were examined in the works by Inyushkin et al. [9, 13].

Previous legal studies related to genomic research mainly examined the regulatory framework in view of legal conditions and practical procedures without regard to information systems.

This article gives a comprehensive vision of the scope, parties and particular application of information systems in genomic research, as well as a long-term outlook of using various information technologies in fixing the circadian gene research findings.

The purpose of the study is to reveal the peculiar features of information systems' application in genomic research, including the circadian genetics topic, and to establish the consistency of general and special rules in this regard.

In the course of the study, we have utilized both general and specific methods of cognition such as interdisciplinary, systemic and dialectic, etc. The methods allowed us to estimate the application of information systems in genomic research, including circadian genetics topics, from the perspective of general terms "information contained in databases" and "information technology and hardware for its processing".

The proceedings of domestic and foreign academicians dedicated to the legal regime of information, including personal data and genomic information, as well as the principles of information systems' performance have made up the doctrinal foundation of the study. The current information and related laws of Russia served a legal background of the study.

The problem has been investigated in two stages:

- at the first stage, we reviewed the scientific literature on the subject of research, as well as the law establishing the legal regime of information and the basic principles of information systems' performance;
- at the second stage, we made conclusions regarding the scope, parties and particular use of information systems in genomic research, including circadian genetics topic.

3 Findings

3.1 The Scope, Parties and Particular Use of Information Systems in Genomic Research

Nowadays, when exchanging genomic information referred by the Federal Law No. 152-FZ as of July 27, 2006 "On Personal Data" (hereinafter – the Law on Personal Data) to personal data, it is necessary to take into account the conceptual framework enshrined in the above act.

The use of genomic information means taking a series of actions aimed at receiving, storing, providing to third parties, accounting, etc.

The terms and procedure for these actions have great importance, allowing to ensure respect for the rights of ones who own this type of personal data. Moreover, these procedures can be performed with or without information technology.

Among the parties of relations arising in connection with genomic information, the Law on Personal Data enumerates, first of all, an individual whom the identifying personal data belong to. In addition, the lawmaker introduces the term "operator" which means the authorities, physical and legal entities involved in the data processing, and also refers third persons having access to personal data or whom personal data may be disclosed to as the parties to relations.

However, as provided for by law, genomic information may be included in the information base. When using information technologies it's conventional to apply terms "information providers", "users" and "system operator" to designate persons dealing with genomic information. In this connection, it is difficult to distinguish between the legal status of parties to relations arising relating to genomic information, depending on the use of information bases in data handling. In particular, the Law on Personal Data interprets the status of a system operator in much broader terms, without limiting his activities by information bases.

In the literature, it is reasonably highlighted that the terms of information acquisition from non-publicly accessible databases, the content of the relevant information and the method of provision should be explicitly referred to the user categories. Users of information systems in the above situation have not only access information, but also sometimes they are obliged to use it for limited purposes and in a particular way [1–4].

The exchange of information falling under state genomic registration is governed by "autonomous" regulatory enactments. The development and operation of information databases in this field are thoroughly governed by Federal Law No. 242-FZ as of December 03, 2008 "On State Genomic Registration in the Russian Federation". The Federal State Institution "Forensic Center of the Ministry of Internal Affairs of the Russian Federation" holding the registration, storage, and classification of genomic information by compiling a federal database and forensic departments of the territorial bodies of the Ministry of Internal Affairs are involved in state genomic registration.

Penitentiary institutions (as for imprisonment) are keeping the records of persons to be registered and extracting biological material. Law enforcement agencies specified in the law have access to genomic information. The scientists have repeatedly stressed the need to broaden the scope of persons falling under genomic registration and the list of its grounds [14].

When holding border control, the federal security service also takes some operations on the processing of personal data (including genetic information) to the categories of persons specified in government rules and regulations. The information is processed, recorded, classified and stored in specialized information systems of the relevant authorities.

3.2 The Application of Information Technology to Fix Circadian Gene Research Findings

To appropriately fix circadian gene research findings in the context of a widespread transition to digitalization, it is necessary to define the suitable objects. Clause 2 of The Information Law provides twenty regulatory definitions. Among the definitions specified in the law, special attention should be paid to "information", "information technology" and "information system". The definition of information in the Information Law differs from the terms given in Part 4 of the Civil Code of the Russian Federation. So, the common civil law uses the term "physical carrier" without interpretation. To establish suitable objects for the circadian gene research findings we should examine the terms that fill the legally protected results of intellectual activity with content [10, 11]. Physical carriers today perform the function of a physical form of intellectual property. The physical database carrier will be a memory module connected to a computer (flashcards, disks, servers, including cloud data storage). In

this case, the physical expression of the database on circadian gene research findings will an electronic memory unit with such data.

In addition to the term "physical carrier", the law-maker uses the term "instance". As far as "physical carrier" and "copy of the work" are not defined in the law, the terms should be interpreted as synonyms [10, 11]. The difference is that a physical carrier is a physical form of databases, separated from them. Deleting information on the circadian gene research from the physical carrier leaves it without a legal connection with the database. The use of the word "instance" captures the legal connection with the database, since this is a derivative state of the physical carrier.

As for the objects to fix circadian gene research findings, we should make a long-term outlook of using blockchain technology for these purposes. Blockchain technology is also associated with databases because they take on a high-tech form. For example, a cloud storage database and decentralized registries will not have the original without a unified data repository. The cloud storage has a network structure, therefore geographically servers can be remote. The geographic location of data servers means different jurisdictions, which entails cross-border relations [12]. The intensive development of open data on the Internet proves the legitimacy of cross-border relations.

It's worth noting that the term "information system" stipulated by the Law on Information refers to databases, therefore, from the standpoint of public law it will be easier to use this object to fix the circadian genes research findings governed by a great number of special legal acts on exchange of information [13]. In particular, the law on personal data employs similar terms and also refers to "database" as a basis for fixing the respective legal relations.

Severally, let's explain the second term "information technology" set out in the article, which is contained in the definition of an information system. The law provides that information technologies form information handling actions or ways of execution of such processes and methods. Bearing in mind that circadian gene research and recording its findings on a physical carrier is quite conceivable to refer to actions, they can fall under the Law on Information. The statement regarding the provision and dissemination of information is of interest in the definition of information technologies. These terms are contained in the Law on Information and are reduced to an establishment of the scope of persons having access to relevant data. This rule should be observed when recording the circadian gene research findings and compiling a corresponding information system, especially when using cloud storage and online servers. The cross-border relations in this field may have an impact on the exercise of the rights to circadian genes research findings by owners. In particular, when drawing up a corresponding information system, it is advisable to indicate the information contained in the database, owners of the right to the circadian gene research gene, and the way this information system will be used. These measures will offset the risks associated with the utilization of the information system, as well as eliminate the discrepancies that may arise in interpreting the information exchange law.

4 Conclusion

Genomic research should be closely related to the application of state information systems.

Since both direct and indirect application of genomic information is allowed (in particular, as a user of the information base), the authors suggest developing the communication mechanisms for various structural and other units of the field (system) within which this application is allowed by law. It's urgently required to advance the legal conceptual framework, especially concerning the establishment of parties, for differentiation of the legal status of parties depending on the application of information bases when dealing with genomic information. The introduction of information technologies in genomic research and development of databases claims, on the one hand, to bring them into line with the general guidance notes concerning any information databases, and on the other hand, to distinguish between cases of exchanging genomic information out of them. Such an approach will make it possible to clearly define the persons who are responsible for the security of genomic information.

By the example of circadian genes, we have presented a positive outlook of using blockchain technology to fix circadian gene research findings and have discovered the impact of cross-border relations in this field on the exercise of parties' powers.

Metaphysical Balance Hypothesis of Humankind Progress and Regress in the Theory of Economic Development

Vladimir V. Skalkin, Aleksandr P. Shcherbakov, Andrey V. Dubrovskij, and Sofia A. Sidorova

Abstract *Purpose*: The purpose of the study is to define facets of the metaphysical balance in the theory of economic development in the context of humankind movement to perfect market. *Methodology*: We base the methodology of the study on the market paradigm viewed through the prism of metaphysics. Therefore, on the one hand, the world is seen a subjective idealistic category through which market runs a red thread. On the other hand, we consider metaphysics from ethical perspective of moral choice and from the standpoint of material relationships development. *Findings*: We show that the source of metaphysical balance is the fruits of the Fourth Industrial Revolution. At the same time, on the one hand, we conclude that the Fourth Industrial Revolution is the path to perfect market and the achievement approach of individuals' equality for access to economic wealth. On the other hand, the Fourth Industrial Revolution leads humanity to effeminacy and deprives the possibility of striving forward and ability to struggle. *Originality and recommendations*: We introduce the metaphysical balance concept as a unity and struggle of opposites. Moreover, the market paradigm is proposed for the economic development of humankind as the most effective social technology that creates the conditions for competition and provides equal access to economic benefits of each member of society.

1 Introduction

In this work, authors proceed from the assumption that all human efforts to improve their lives lead to a simultaneous deterioration of human nature, thereby forming a metaphysical balance. In accordance with metaphysics, the human essence is unchanged, and as if the human had not hesitated to change anything their life for the better, the general balance of progress and regress remains unchanged from the point of view of the constancy of the human nature.

Therefore, it is not surprising that the Fourth Industrial Revolution raises the question of whether humanity is moving towards progress or whether new technologies are leading it to regress. In scientific circles, this issue has become widespread nowadays. Thus, Nassim Taleb, in his book "Anti-Fragility," makes the assumption that any change associated with economic and social progress has two sides, and one of them is an increase in fragility and instability [1].

2 Methodology

Authors believe that the basis of the market paradigm is metaphysics in its classical sense: "In the beginning was the word …" (John 1:1).[1]

The word "Metaphysics" - from ancient Greek is translated as "above nature" or "outside of nature". It studies the questions of things beyond its physical nature, its essence and the properties of being. Metaphysics seeks to answer the questions: "what is it?" [2].

A similar definition is given in the Russian language dictionary of Vladimir Dahl. According to him, Metaphysics is a doctrine of the non-material world, of the essential, spiritual; that is subject to human feelings [3].

At the same time, according to the Stanford Encyclopedia, metaphysics is a branch of philosophy that studies the essence of things. It includes questions of being, becoming, existence, and reality [4].

That is, according to these definitions, the world is considered from the point of view of pure ideas about it.

However, in the framework of this study, the following definition of metaphysics is proposed: metaphysics is the doctrine of the primary source of world creation, of the nature of being, of the true essence of things, of that which is unchanging.

In the general case, the concept of metaphysics is necessary for the full definition of a new term, which is the core of the concept, the metaphysical balance. Since metaphysics gives an idea of the independent essence of human, the hypothesis is put forward that any action associated with progress, from the point of view of human nature, automatically leads to regress by the same amount. This is a dialectical property of metaphysics, due to the unity and struggle of opposites.

[1] In the beginning was the Word, and the Word was with God, and the Word was God (John 1:1, KJV).

That is, on the one hand, metaphysics is considered from the point of view of the invariability of human nature in terms of the manifestation of moral and ethical qualities and the dilemma of choice. On the other hand, in connection with the development of material and substantial relations, a human can discover new features in themselves that determine both their progress and regress.

According to Italian Renaissance thinker Giovanni Pico della Mirandola, a human's essence is infinite and different from any fixed being. In his famous "Speech on the Dignity of Man," he noted that the dignity of human stems from the fact that God did not give them a pre-fixed nature [5]. The effect of progress, or rather what humanity calls progress, on the nature of human, and ultimately on economic choice, is quite obvious.

An increase in labor productivity, an improvement in the human life condition, is the external side of progress, its material component. It should be emphasized that from the point of view of metaphysics, the choice is not made in the sphere of material objects, the choice is, first of all, the category of morality. Therefore, the question is quite appropriate: does progress change the nature of human, does it improve it.

When analyzing the impact and consequences of introducing a new technology, as a rule, the benefits and costs are measured, and possible increments of quantitative and less often qualitative indicators are considered [6]. However, few people think about how new technology affects the nature of a man.

According to Karl Marx, the human essence is an infinite ability for self-realization in labor [7]. However, to what extent the fruits of the Fourth Industrial Revolution, with its tendency toward the total domination of artificial intelligence, contribute to the discovery and realization of the human essence, is a huge question.

3 Results

Currently, there is a tendency for the development of human civilization, which leads to what is called the movement towards a perfect market. This idea was expressed by the famous futurologist Michio Kaku [8]. At the same time, Nick Hanauer believes that market is the most efficient social technology [9]. Earlier, Ronald Coase said that humanity is separated from the perfect market by the presence of transaction costs [10]. In other words, a perfect market exists in the absence of transaction costs.

The general definition of market dates back to the teachings of Adam Smith and his fundamental work, The Theory of Moral Sentiments [11]. The category of market is reduced to a moral imperative, which consists in an honest and fair exchange between two entities (a person, a company, and a state) at a price that both parties consider fair. Moreover, the parties are equally informed about the subject of the transaction, excluding the asymmetry of information.

The fundamental principles of market follow from this definition: the principle of freedom of choice with minimal asymmetry of information: "I want, I buy"; principle of no bargaining. These are the principles of natural behavior. The first principle assumes that the buyer is sufficiently aware of the subject matter of the

transaction and is not guided by coercive motives. The second principle implies that bargaining acts as a transaction cost that impedes an honest and fair exchange. On the one hand, bargaining acts as a "grope" for a fair price; on the other hand, the motives for bargaining are determined by the desire to appropriate something else [12]. So, according to G. Akerlof and R. Shiller, bargaining gives rise to deception and veiling of truthful information. Their theory is known for the phish and phool categories. Phish is understood as manipulations performed by the seller over the buyer. A phool falls into the category of a person who, for whatever reason, was successfully caught by the "fishing rod" of such manipulations [13]. Nevertheless, those who catch the "phish" have a greater chance of falling for the "bait". In other words, the deceiver will ultimately be deceived by themselves.

This definition implies a sufficient degree of information transparency of individual economic agents, which is achieved in a digitalized economy.

Thus, moving to the market involves reducing transaction costs, including those related to finding the necessary information to make efficient management decisions [14]. Moreover, all the achievements of the Fourth Industrial Revolution, one way or another, are aimed at reducing them, since they create a single information space.

At the same time, the metaphysical nature of the market and market relations is, first of all, embodied in the very definition—exchange, which requires nothing but two individuals who decide to receive one good in exchange for another. Such a deal can be concluded in any society, anytime, anywhere in the world. The market runs as a red thread through successive civilizations and is not dependent on a change in society, including its material and substantial structure. However, the Fourth Industrial Revolution reveals more fully the essence of the market and market relations, in accordance with its original definition [12].

In this context, it should be emphasized that the fruits of the Fourth Industrial Revolution can be viewed not only from the perspective of reducing transaction costs. The very perception of honest and fair exchange is changing. That is, categories such as honesty and justice have evolved in understanding and their definition. At the same time, the question is raised of the equality of individual beings, including social equality.

People are born free and equal. The divine principle does not divide the hierarchy. Hierarchy is an invention of mankind. However, despite the increase in freedom and the reduction in transaction costs, inequality has been increasing throughout the history of humankind. In this sense, all attempts by great philosophers, thinkers, politicians to smooth over the existing inequality are doomed to failure.

An example of this is the Universe 25 experiment: "A Paradise Became Hell", conducted by Calhoun [15]. The experiment was conducted on mice provided with equal conditions for access to food. In the created environment there were no predators, diseases were treated. There was room for breeding. Deprived of incentives for struggle and the manifestation of social roles, mice began to turn into autistic "handsome men" capable of only the most primitive functions: the absorption of food and sleep. The "handsome" refused all complex and demanding tension and, in principle, became incapable of strong and complex behavior, which ultimately led to their death. In other words, the death of the spirit entails the death of the body. People

deprived of incentives to fight do not see the point in life, and therefore degenerate. Therefore, a key feature of a living creature, including human nature, is to live in conditions of pressure, tension and stress, for which human receives an appropriate reward from the market.

Thus, when "greenhouse conditions" are created, there is either a decrease in the will to fight, or a change in its trajectory in an unproductive direction, such as towards satisfying bureaucratic requirements to the detriment of the reproduction of goods that satisfy the needs of individual beings.

At the same time, the Fourth Industrial Revolution stimulates the introduction of "artificial intelligence" on a universal basis. A key feature of the new industrial revolution is intelligence and flexibility [16]. At the production level, there is a focus on the widespread introduction of an analogue of the "Internet of things". Assembly lines, machines, and plants will link through interconnected networks [17]. At the level of life of an individual being, ubiquitous chipisation takes place, which reduces costs at the household level, including economic transactions. The development of computer technology leads to changes in the areas of the human brain at the level of physical processes. Thus, the pampering, which is stimulated by the fruits of the Fourth Industrial Revolution, leads a person to regress. Thus, the experiment of the Fourth Industrial Revolution can become for humanity an analogue of the Universe-25 Experiment, which led civilization to decline.

Therefore, the metaphysical nature of market also manifests itself in the struggle of the directions of one of the instruments for its achievement - the development of technology. One direction associated with reducing transaction costs that impedes the achievement of a perfect market, expressed in the moral imperative of honest and fair exchange, leads humanity to progress. The second direction, associated with the lack of the need to carry out previously familiar transactions on their own due to an increase in the availability of getting what they want, in other words, with the lack of struggle, leads humanity to regress.

But does humanity really want equality? According to numerous studies, people would hardly prefer equality in which absolutely all people would live in poverty. People complain that they get less than others, but do not grumble when they get more. Therefore, equality is not what people really want [18]. On the contrary, only struggle, fair competition, moving forward, overcoming difficulties can lead a person to the happiness of dedication and good spirits, which is a fundamental condition for the survival of humankind. All this is achieved with the help of the free and fair market relations. On the one hand, the free market creates the conditions for competition; on the other hand, it ensures the equality of each individual, including access to economic benefits, since the "ventilation" between the social strata in the market economy is much higher than that of economies with strong government intervention, replacing the "invisible hand" of market.

4 Conclusion

In this study, the progress and regress of humankind is examined in terms of a metaphysical balance. The source of such balance is the fruits of the Fourth Industrial Revolution, associated with the formation of a single information space, flexible production systems, the development of computer technology, the development of the digital economy, followed by the widespread introduction of chips. On the one hand, it is concluded that the Fourth Industrial Revolution is the path to a perfect market, since the transaction costs of economic agents are reduced, information asymmetry is eliminated. In other words, this is the path to the moral imperative of honest and fair exchange. At the same time, this is a means of achieving the equality of individuals, which philosophers, thinkers, and politicians are actively striving for, recognizing the active participation of the state in economy. On the other hand, the development of technology leads humanity to effeminacy and makes it impossible to strive forward and actively struggle. However, people do not so much want equality as the happiness of dedication in their chosen activity. Moreover, market is the most efficient social technology, because, on the one hand, it creates the conditions for competition, on the other hand, it provides equal access to the economic benefits of every member of society.

The Transformation Specifics of Property Relations under Digitalization in Modern Russia

Alexey M. Tsikin

Abstract The work is devoted to the analysis of the process of transformation of property relations under digitalization that accompanies the development of the national economy. The purpose of the work is to develop scientifically grounded recommendations for increasing the competitiveness of the economy through the transformation of national property relations. To achieve this goal, the current state of property relations in Russia is characterized, the factors determining the vector and intensity of transformation are systematized, and mechanisms for the development of the Russian economy based on ensuring its self-sufficiency are proposed. Methods of general and system analysis are used in the work. As a result of the research, mechanisms for ensuring economic development are proposed based on the principles of ensuring the self-sufficiency of the national economy and the corresponding transformation of property relations. The results of the work can be used in the development of both a strategy for increasing national competitiveness and state economic policy in general.

Keywords Property relations · Competitiveness · National economy · Self-sufficiency

1 Introduction

Property relations are a process of appropriation and alienation of the means of production, labor and consumer goods, covering all stages of the cycle of social reproduction. After the collapse of the USSR, property relations in Russia were deformed, which was one of the reasons for the economic decline. Largely due to the lack of thought in the relevant state policy, the current state of the Russian economic system is characterized by high uncertainty of external and internal factors, a crisis of existing models of economic development, and a lack of a common understanding of the country's development vector.

Property relations in the modern world are constantly becoming more complicated, diversified, and deformalized, which leads to the need to re-actualize ideas about the subjects and objects of property [12]. This necessitates the analysis of problems and prospects for the transformation of property relations in modern Russia. This goal becomes especially relevant in the context of the need to develop the Russian economy on the basis of new concepts, in particular, the model of digitalization and new industrialization [4]. The implementation of the corresponding task requires the transformation of property relations, considered in the work as a process of transforming elements of the property system and relations between them under the influence of external and internal forces, the vector of which is aimed at building a self-sufficient economic system.

2 Methodology

The centuries-old experience of the surrounding reality cognition suggests that dialectical (historical) materialism is the main methodological apparatus. Appropriate considerations can undoubtedly be used to analyze the problems and prospects of the transformation of property relations in modern conditions. It should be noted that at present in economic science not enough attention is paid to the philosophical understanding of the problems that arise, despite the fact that only using the apparatus of dialectical logic one can form truly scientifically grounded recommendations for the development of the Russian economy.

The basic laws of dialectics, taking into account the principles of historicism and constitency, are used to select modern factors that determine the transformation of property relations and develop recommendations on the use of modern property relations in the context of the Russian economy's digitalization.

The theoretical and methodological base of the work was the research of leading Russian and foreign scientists and economists in the field of market economy, institutional economics, and economic philosophy. The official data of the Federal State Statistics Service of Russia and the World Bank were used as an information base in the work.

3 Results

The main forms of ownership in accordance with the dialectical principle of the unity of the individual and public are private and public. And in the context of the development of the Russian economy, one of the first questions is the protection of property rights. Among the many positive factors affecting competitiveness, it should be noted that the protection of property rights is one of the foundations for creating a favorable business climate in the state. The result of this process is the growth of long-term investments from non-state sources, which is necessary today

in Russia. Most researchers define precisely the increase in long-term investments as the basis for economic growth in the conditions of protection of private property rights [10, 11, 18].

However, equality of ownership forms enshrined in Russian laws does not mean equality of conditions for the realization of economic interests. The state in Russia has special conditions and the priority of its economic activity. Special conditions are implemented through a special taxation regime (reduction of tax rates, provision of tax credits and restructuring of payments on taxes and fees) and a financing regime (subsidies and soft loans) [15].

The working hours of private organizations and the population are significantly different for the worse. Private firms conduct business in a competitive environment, often confronting state and foreign organizations that receive significant financial and administrative support. Due to the policy of the Central Bank and the sanctions restrictions imposed on Russia, access to financial resources to private organizations is much more difficult; loans are granted on bondage terms. In addition, the activities of private enterprises are complicated by constantly increasing tariffs for energy and services of natural monopolies. Unequal economic conditions for public and private organizations are one of the reasons for the prosperity of economic violations in Russia.

Excessive predominance of state ownership in the economy leads to an increase in bureaucracy and the burden on the budget, and a decrease in the adaptability of enterprises. The other extreme (excessive share of the private sector) can lead to a deterioration in the standard of living of many social groups, the accumulation of social problems and the violation of the structural integrity of the economy [14]. At the same time, funding for basic scientific research, R&D, health care and education that negatively affect competitiveness may be reduced, worsening the position of the national economy in virtually all areas of competitiveness development. One can cite an example from the recent past, when after the collapse of the USSR as a result of privatization the share of the public sector decreased excessively (Table 1) with the negative consequences mentioned above.

At the same time, the main directions of the property relations' transformation after the collapse of the USSR were declared to be the privatization of state enterprises and increasing the efficiency of the remaining state organizations [23]. We should state the "success" of solving only the first task. During the privatization of state property, it was necessary to resolve two contradictions: between the need to obtain state revenues through the sale of property and the lack of appropriate solvent demand, as well as the theoretically existing possibility of selling shares in profitable industries and their low market valuation. Today it can be argued that the very need for privatization should have been subjected to critical analysis, as studies show that the implementation of the second strategic direction (increasing the efficiency of state-owned enterprises) can produce a positive effect no less than large-scale privatization [13].

It is interesting to trace the relationship between the state ownership share in the Russian economy and the tendency of the population to accumulate (Fig. 1). Until 1998, the decrease in the accumulation rate and the state ownership share is

Table 1 The structure of Russian fixed assets

almost synchronous. However, in the longer term (until 2017), the construction of trend allows concluding that there is a similar change in the analyzed indicators. This circumstance allows concluding that the transformation of property relations in Russia directly affects the use of GDP after the collapse of the USSR. The corresponding high consumption rate also imposes restrictions on the list of possible mechanisms for the development of competitiveness in the short term.

Analyzing the recent historical past, it becomes obvious that the concentration of the vast majority of organizations in the public sector in the USSR made it possible to concentrate capital and develop entire industries (oil and gas industry, ferrous and non-ferrous metallurgy and others) with stable regional and sectoral ties, then called “clusters”. Under the monopolism of big business after the collapse of the USSR, price liberalization led to an imbalance in social reproduction due to limited demand for the products of enterprises oriented towards the end consumer. As a result of this process, enterprises at the beginning of the reproduction cycle (as a rule, enterprises of the raw materials sector) received unreasonable competitive advantages over organizations in the manufacturing sector. “Thanks” to the noted imbalance in social reproduction, the dependence of the domestic economy on the efficiency of extractive industries and the prices of basic energy resources has intensified.

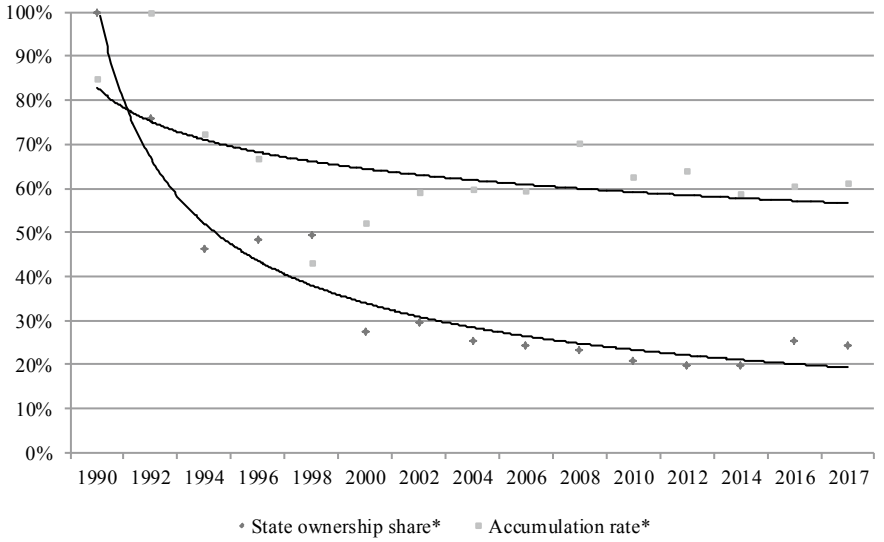

Fig. 1 State ownership share and accumulation rate in Russia in 1990–2017. *Source* Russian statistical yearbook (1997–2018) ,*normalized values of indicators are presented

At present, almost half of the crude oil produced is exported abroad [8], which significantly exceeds this indicator during the Soviet era [5]. The situation is similar in the gas industry: both from the extremely low gasification of Eastern Siberia and the Far East, and from the predominant use of gas as fuel, although it is more justified to produce on its basis a wide range of products with high added value.

In the context of a decrease in the state organizations share, the implementation of large projects can be difficult. An analysis of the structure and volume of investments in Russian fixed assets by ownership (Table 2) allows concluding that the goals for attracting investments declared during privatization did not materialize. The structure of investments as a whole corresponds to the structure of ownership (Table 1), and gross investments do not seem sufficient to update fixed assets. It should be noted that Russian State Statistical Service itself in its statistical yearbooks indicates that the most significant impact on investment activity of both Russian and foreign investors is the lack of own financial resources (57% of the total number of organizations surveyed), a high percentage of commercial credit (53%), investment risks (51%), the uncertainty of the economic situation in the country (57%), and the low profitability of investments in fixed assets (20%) [17].

The noted features of the current stage of the Russian economy's development have led to the fact that the modern economic system of Russia can be represented in the form of two poles [2]:

- the global system periphery, which includes enterprises of the commodity sector and manufacturers of goods with low added value (mainly a large domestic business with bureaucratic support from the state);

[a]summarized investments in fixed assets, RUB billion

- the sovereign competitive national economy, represented by manufacturers of high value added goods (mainly small and medium businesses).

There are two possible scenarios for leaving the periphery of the world economic system that require an adequate transformation of property relations: a transition to the center of the world economic system or the development of a self-sufficient economic system. The second development path should be chosen as a priority, involving the closure of the rent being collected on the national economy. The development of a self-sufficient economy requires significant resources and an effective public policy, but for political and economic reasons it seems more acceptable.

The development of a self-sufficient economic system should be based on moving away from the raw material vector of economic development towards innovative industries. The task of Russia is the transition to new technological structures [9], the creation of prerequisites for the formation of the competitiveness of the national economy at a new technological stage. Without developing a concept to increase competitiveness, existing sources of economic growth will be lost, and the country will be finally thrown to the periphery of the global economic system.

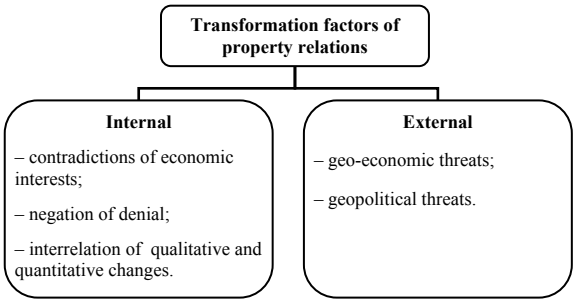

Fig. 2 Factors of change in the direction of property relations' transformation. *Source* Compiled by the author basing on work [19]

Sokolov in his work proved that today internal and external factors influence the direction of transformation of property relations in Russia (Fig. 2).

The main external factors that change the vector of transformation of property relations are geo-economic threats associated with the functioning of the modern world economic system. The modern capitalist system of the world order aims at minimizing costs in order to maximize profits. The result of this installation is a number of environmental problems, the most significant of which is the widespread pollution of the atmosphere, soil and surface water as a result of the active use of chemicals in agriculture, in the process of extraction and processing of fuel and energy resources, including coal, oil and gas. These problems are especially acute in developing countries with corruption-intensive and insufficient control of environmental regulatory authorities. In addition, among the geo-economic threats, one can note the deformation of moral and moral values that are characteristic of a Western consumer society, due to which large multinationals have the opportunity to expand the market for their products and maximize profits [6]. The result of modern geo-economic factors will most likely result in the formation of several regional systems for the division of labor, and Russia still has to defend its place.

Geopolitical factors consisting in the presence of global centers of instability both near Russian borders and in the whole world, in addition to obvious threats, can lead to the development of national competitiveness using adequate methods of state regulation. The chaotization of the external environment leads to the need for the development of the Russian defense industry, in addition to economic reasons related to increasing the self-sufficiency of the economy and facilitating the processes of cluster formation, also includes a political component. The concomitant limitation of private property appropriation, de-offshorization of business and the correction of ownership forms strengthen the position of domestic enterprises in the world market and develop competitiveness at all levels.

Internal factors of transformation of property relations primarily contain contradictions of national economic interests caused by the opposition of the social nature of production and the ownership of national resources with the personal appropriation of production results and income from the sale of national wealth. One of the alternatives to market coordination of economic interests of agents is the use of a bureaucratic apparatus [1].

The dialectical law of negation of denial is manifested in the analysis of the ownership structure in Russia. Historically, the Russian economic system has been characterized by a high share of public (state) property. When conducting privatization processes imposed from outside, the ownership structure changed dramatically (Table 1). Thus, we can talk about the operation of the law of negation of denial, and therefore the possibility of a return to the priority of public property and national economic interests.

Qualitative changes in the structure of Russian property in the 1990s led to a quantitative change (deterioration) in national competitiveness indicators. Without the overdue transformation of property relations, we can expect further degradation of the domestic economy and its consolidation on the periphery of the world economy. At the same time, a combination of factors negatively affecting competitiveness, and their quantitative estimates, suggests the possibility of a qualitative change in property relations in modern Russia.

Modern factors of transformation of property relations in Russia are aimed, rather, not at the formation of a self-sufficient competitive economy, but at further drawing Russia into the periphery of the global economic system. To overcome this negative influence from the state, it is necessary to qualitatively change the policy of state regulation of the economy, to increase the effectiveness of state control and supervision, especially in the financial sphere. Equally important is the creation of comfortable working conditions for domestic business in terms of limiting bureaucracy, pressure from law enforcement agencies, and ensuring the rule of law and a free judiciary. The task of private business is to implement in its development strategies the satisfaction of public interests as opposed to personal enrichment and pursue a policy of de-offshorization, withdrawal of cash flows from foreign to domestic jurisdiction.

To implement these areas, it is necessary to solve a whole range of practical problems related to the development of small and medium-sized enterprises in the country, the formation of a favorable business climate, increasing the availability of financial resources for the modernization of production, the effective use of state property for the realization of public interests, a rational policy of protecting domestic producers, and improving general ownership structure in the country. The formation of the economy competitiveness is also inextricably linked with ensuring the self-sufficiency of the national economic system, contributing to the withdrawal of Russia from the periphery of the world economy. The solution to these problems is impossible in a weak state.

An analysis of the phenomenon of exceptional American competitiveness and state participation in the process of developing competitive advantages performed by Porokhovsky shows that, in contrast to European countries, the United States managed to secure strong state power with a small formal participation of the state in economic activity [16]. In the American model, the share of government spending in the structure of GDP and the share of the population employed in the public sector are much more significant. The structure of relevant indicators in the Russian economy shows that the state's final consumption expenditures in Russia are at a level and even surpass the United States (Fig. 3).

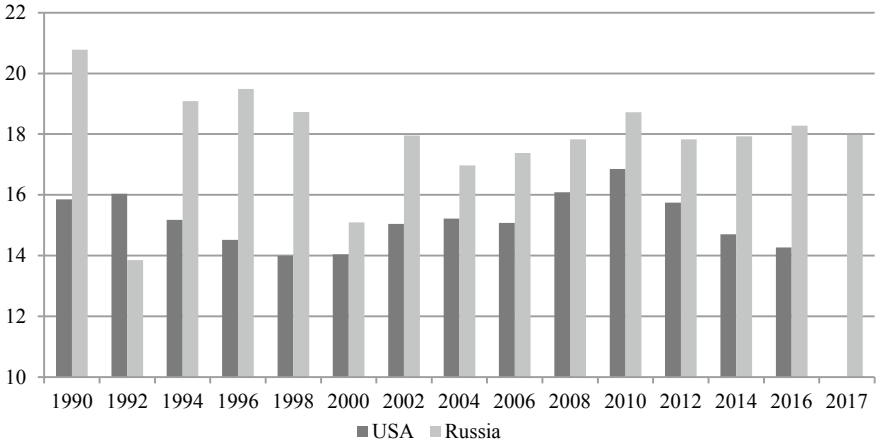

Fig. 3 Government spending of Russia and the USA in 1990–2017, % GDP. *Source* World Bank [21]

The share of the population employed in the Russian public sector is also large (Fig. 4) and significantly exceeds the United States [20]. The totality of data on the size of state ownership, the share of government spending and the number of people employed in the public sector makes it possible to raise the question of the need to increase the efficiency of the state apparatus, and not its absolute growth. In modern Russian conditions, it is advisable to use mechanisms to increase the competitiveness of the economy associated with the transformation of property relations, in which financing large projects should be carried out not only at the expense of state finances, but also using private capital, which increases the economic interest of business in achieving common economic interests.

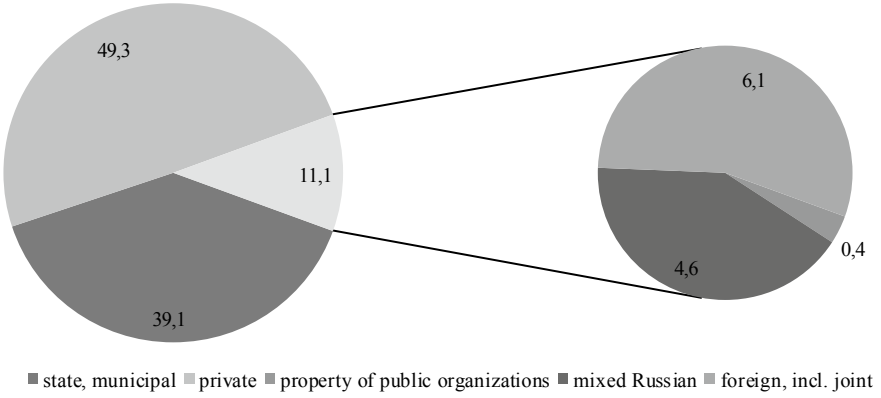

Fig. 4 The average annual number of employees by organizations ownership, %. *Source* Russian statistical yearbook 2018

One of the features of the modern institution of ownership is the diversity and heterogeneity of key actors in the economy, which include inter-level systems such as public-private partnerships [4]. Various types of such associations are today regarded as the main mechanism for realizing the common economic interests of individuals, business and the state. At the same time, due to the high importance of projects financed by on a state basis, legislative regulation introduced in Russia from January 1, 2016 is necessary [7].

The use of public-private partnership mechanisms is especially relevant for the supporting sectors of the Russian economy, which include production that are the world leader or have the corresponding potential, ensuring the country's independence, as well as solving social problems. At the same time, it should be agreed that there is no prospect of using public-private partnership methods for social facilities due to the lack of clear control over the conditions for the provision of services and the deadline for their provision [22].

4 Conclusion

It is impossible to imagine the development of the Russian economy today without the ripening transformation of property relations, improving the efficiency of managing state property, reducing bureaucracy and corruption, which are the hallmarks of modern Russian society. It is necessary to maintain sufficient weight of the public sector required to ensure state economic security, regulate the activities of private market structures, and the possibility of influencing the competitiveness of Russian products in the national and world markets.

The use of modern models of development of the national economy (first of all, neo-industrial concepts) requires taking into account the problems and prospects of transformation of property relations, recommendations on the use of modern mechanisms of public-private partnership, considered in the work. The state should play the main role in this process.

Russian Economy: The Reality of Stagnation

Larisa G. Cherednichenko and Irina P. Komarova

Abstract Purpose of the paper. The article estimates the medium and long-term prospects for the development of the Russian economy. The research method used is the historical one, as well as structural and comparative analysis. Findings. Potential opportunities for economic development and threats to it are identified. It is concluded that current fiscal policy constrains incentives for economic growth. Recommendations: The authors propose alternative sources for launching multiplying processes in the economy and define key goals of industrial policy in Russia.

Keywords Economic growth · Fiscal policy · Investment · Innovation · Human capital

Jel Codes E65 · E66

1 Introduction

Making a breakthrough is not just speeding up the pace of economic growth or improving the standards of the population's life. In the context of dramatic technological, political and socio-economic changes, a breakthrough is foremost a restructuring of the economy and establishing the essential conditions for future development.

The history of the global economy has proved the fact that the framework of the international labor division suffers major changes in terms of technological transformations. Some industries are fading and entirely new that can drastically change the path of further economic development are emerging. The opportunities and prerequisites for changing the current balance of power on the world stage bring some threats

and restrictions, for example, the stickiness of the current scenario of the Russian economy development.

An economic breakthrough can be ensured by shifting from a stabilization strategy to a growth one. This idea is stressed in Presidential Decree No. 204 as of May 7, [1], "On National Goals and Strategic Objectives of the Development of the Russian Federation until 2024". The decree sets the main guidelines for the development of Russian society but does not directly present a development model of the Russian economy.

2 Methodology

The methodological background of the study is laid by neoclassical and institutional theory, as well as one of economic growth.

3 Findings

The economic outcomes of 2019 are ambiguous. On the one hand, as a result of the first three quarters of 2019, most macroeconomic indicators showed a weak trend. Economic growth slowed down to 1.1% per annum, the growth rate of retail trade and investment declined.

On the other hand, industrial production and agriculture make a good contribution to economic growth; wholesale turnover has also returned a positive trend. However, despite the better macroeconomic situation, it is most likely that the average annual growth rate of 1.3% planned in the Federal Budget of the Russian Federation won't be reached.

From the viewpoint of economic development prospects in 2020, GDP growth is expected at the level of 1.5%. The main restraint is sluggish consumer demand. Its declining contribution to GDP growth is supposed to be offset by higher budget expenditures.

The choice was made in favor of state investments, the effectuation of which is associated with the need to multiply budget revenues [2]. A wide range of government measures are aimed at this, in particular, increasing the VAT rate and cutting tax benefits. But, solving the problem of the current budget replenishment, the financial authorities forget about side effects. The higher tax burden will inevitably lead to the suppression of economic activity in the country, the oppression of business and the constraint of consumer demand of households. Here, there is an imbalance between the goals of the fiscal policy and its methods, which has persisted for several years [3].

In our opinion, investments should be effected not through higher tax burden on business and population but with the help of the available reserves.

Table 1 The structure of populations' savings[a]

February 2019	32,884.3	21,792.9	66.3	6,070.5	18.4	5,020.9	15.3

Source developed on the back of data from the Federal State Statistics Service, https://gks.ru/free_doc/new_site/population/urov/doc3-1-2.htm

[a]Deposits in foreign currency accounts and foreign currency in hand of the population are not taken into account

The current approach to the management of Russian sovereign funds is under a big question. The operating model based on the Santiago principles turned out to be ineffective from the standpoint of pursuing the state economic policy. The management of funds is reduced to financing the foreign currency and is not oriented at real investment in economic development.

Another potential source of investment-financing in the Russian economy is public funds. According to the Federal State Statistics Service, the total amount of population savings amounted to 32.9 trillion rubles as of February 1st, 2019 (Table 1).

At the micro-level, private companies have long attracted public funds into specific projects, using technology platforms for their accumulation. However, the huge potential of the population's savings can be used at the macro level, while ensuring the safety of funds invested.

The funds withdrawn from Russia to tax havens deserve particular attention. Russia is the fourth among the countries with the largest share of offshore assets. Wealthy Russians have placed in foreign jurisdictions funds that make up about 50% of the country's GDP. Russia is surpassed only by Saudi Arabia, Venezuela and the UAE [4].

After Russia's accession to the agreement on the automatic exchange of information with the execution of the OECD plan to combat tax evasion, since 2018 the Federal Tax Service has received data on foreign accounts of Russian tax residents. New mechanisms development to attract these funds into real investments and their repatriation could broaden the economy's opportunities to launch multiplicative processes of economic growth.

Besides, the underestimated importance of attracting investors who want to develop export substitution that would give an impetus to the development of high-tech exports brings its consequences [5].

Searching for possible sources of funds for the state economic policy to be pursued in Russia is a difficult but feasible task. It's harder to achieve efficient and targeted spending of funds, i.e. investing them in specific projects that can bring high returns in the future.

Table 2 Domestic R and D costs (% of GDP)

	2012	2013	2014	2015	2016	2017	2018
The total figure across the Russian Federation	1.03	1.03	1.07	1.10	1.10	1.11	1.0

Source Rosstat data [8]

Our country sets oneself an ambitious goal to increase the share of investment expenditures in GDP to 25% by 2024. However, the likelihood of investment and technological breakthroughs for the economy to take a new technological level is low.

Technological progress is a major factor in long-term economic growth.

In 2019, Russia ranked 46th among 129 countries in the global rating of innovativeness, having maintained the position of the last year.

The share of domestic R and D costs in the country's GDP is still negligible, and it fell to 1.0% in 2018 (the global average is 1.7%, in North America and Western Europe is 2.5%) (Table 2). In terms of this indicator, Russia is not even in the top-15 of countries.

The proportion of Russian exports of high-tech goods in total exports of 2019 (January–June 2019) amounted to 11.3%, which is also a very small indicator compared to other countries (about 20% in the USA and about 25% in China).

The oil sector keeps the leading place in the Russian economy, and the sectors affecting the innovative component not yet take the top positions of the global rating (Table 3).

In the field of innovation like in any other economic field, both supply and demand play an important role. The new inventions do not guarantee their introduction into the production of the country of origin. A demand of companies for innovation will be high if only they cannot maintain their position in the market in another way.

This means that companies should hold activities in a competitive environment. Therefore, the import substitution policy should be an intermediate stage on the path to export-oriented development for industries prioritized by the government. Without pressure from the global market, the demand for innovation will be negligent.

Another factor that negatively affects the demand for high technology is low wages. Increasing the average wages (foremost by raising the minimum wage) may

Table 3 Russia's ranking by types of industrial products in the global economy

Types of industrial products	Rank

Electricity, cast iron	4
Timber export, hydraulic cement	5
Coal	6
Cars	14
Paper and cardboard	13

Source Rosstat data [9]

boost the demand for innovations. Expensive labor will make companies seek new forms of substituting labor by capital.

The following priorities can be outlined in the field of medium and long-term areas of state industrial policy:

I. *Promotion of economic digitalization.* The world is passing through a new stage. The developed countries are accomplishing large-scale digitalization programs [6] where the development of digital platforms is of great importance [7]. Russia lags from the leading world economies by digitalization pace. In 2018, for every 10 thousand employees in the industrial sector, there are only four industrial robots. This is much lower than the world average level (85 robots per 10 thousand employees), and miserable in comparison with the leader of robotics, South Korea (about 500 robots) [10].

Very few economic sectors of the Russian economy succeeded much in digitalization (finance, communications, and retail).

II. *Support of tradable industries with high growth potential (chemical, food industry, metallurgy, mechanical engineering).* An analysis of the foreign trade data in the Russian Federation shows a positive trend in exports of the principal types of industrial goods. The state can support enterprises in traded industries by subsidizing the production, providing tax benefits, assisting in the promotion of domestic goods in foreign markets, and insuring shippers' risks.

III. *Investments in human capital*. Investments in human capital, primarily education and medical services, not only raise the living standard of the population and improve the well-being of society but also build the potential for future economic development. Besides, the government should bear in mind the risk of falling into the trap of growing current cost-effectiveness. The problem is hidden in the cumulative effect of investments in corresponding industries. Cost savings and concentration of resources can result in huge losses.

Another side of this problem is that money should indeed ensure the availability and high quality of relevant services, in addition to spending.

IV. *State support of high-tech industries, such as information technology, nanotechnology, telecommunications, bio- and medical technologies.*

The development of high-tech industries is impossible without large-scale government support. Private manufacturers are not interested in establishing capital-intensive productions without guaranteed major orders and reimbursement of start-up investments.

4 Conclusion

Summing up, we would like to note that the government undertakes a huge responsibility for setting the key guidelines of economic development in the period of

transition to a new technological paradigm. Today it is obvious that the priority goals for the state will be the social field, high technology, and the digital economy. Their development directly depends on the quality of the government policy and precise strategic plan of action.

Methodology for Creating a Product Development System Based on Complexity Management Strategy

Ekaterina P. Garina, Elena V. Romanovskaya, Natalia S. Andryashina, Victor P. Kuznetsov, and Sergey D. Tsymbalov

Abstract The article discusses the strategic alternative development of an industry enterprise: the primacy of an engineering idea for a product over the primacy of an engineering idea for production. The object of the study are product development systems, and corporate systems of engineering enterprises. The subject is a set of theoretical and methodological approaches to the formation of product development systems by engineering enterprises. Principles, methods and ways of managing these systems, as well as methodological aspects of their development. The main **objective** is to develop a methodological approach for formation of a system for creating a product of production, based on the management (reduction, retention, increase) of the created complexity. **Methods**. The methodology of design studies was used as a methodological base and heuristic basis of the research process. **The results of the study**. The methodology for creating product development systems is complemented by solutions to manage the emerging complexity due to: a) identify key management complexity challenges faced by the manufacturer; b) formation of a set of guidelines and critical success factors in relation to actions to take into account the complexity of the system; c) complexity management of the product development system in the context of a product life cycle.

1 Introduction

By methodology we mean a set of principles, methods, tools, strategies for developing systems, as well as procedures and requirements, implementation of which allows to get a result.

Based on the position that a product development system serves as a model in shaping the development strategy of machine-building production, we determine the content of the *methodology for creating product systems at industry enterprises* as the following sequence in the PDP approach or the simultaneous development of a set of processes in the CE concept [1]:

1. PD—product development *(where is the PEP product development process)*;
2. MSP—planning of corporate systems (product development systems, production systems);
3. Production.

The conducted research allowed to reveal relevant practices of the *methodology for formation of product systems by* machine-building enterprises (Fig. 1).

2 Research Results

Considering examples of the product systems formation by industry leaders. We determine that the level of the methodology are issued strategic decisions on product and production. Only then - technical and technological and operational solutions for the design of enterprise systems and manufacture [2]. Proposed solution–control and management of the product development system complexity takes into account the following:

1. Stages of the product life cycle (PLC cycle). Implemented strategies on the phases of "input" and "growth" [3, 4]: (a) Differentiation (customization), (b) Cost leadership, standardization (mass production), (c) Hybrid competitive strategy (mass customization). Implemented strategies on the phases of "maturity" and "recession" [5, 6]: (a) Priority of the system functional complexity (b) Priority of the physical complexity (c) The compromise between functional and physical complexity.

In our opinion, the PLC cycle phase affects the set of guidelines for managing product complexity. The priority value of goals with complexity of the system in each phase is reflected in Fig. 2:

2. Key management tasks:

PD life cycle	product development	enterprise systems planning	production
	product development process (PDP)		
process phases	– product planning – project specification – management requirements – conceptual design, system design – layout, technical design, design specifications – modeling, model analysis – project implementation	– conceptual planning of systems, – system engineering; – designing systems in CAD, documentary support – instrumental design of systems; – prototyping, quality control	– planning, arrangement of equipment, – performance planning, design specifications – actual commissioning – assembly, commissioning, start-up
current approaches	Spiral Design, Stage Gate Concept, Funnel Concept, Product Life Cycle Management (PLM) Model	Funnel concept, Axiomatic design concept, Prototype concept, Computer Aided Design (CAD), PDP process prototyping	Lean manufacturing, Kanban pulling system, protection against the "Bye-yoke" error, heijunk, Djidoka, Just in time (JIT); continuous improvement (Kaizen); Six Sigma project KPI, Losses (Muda); visualization (Visual Factory) and others.
fundamental principles	– innovative PD processes – project management – multi-functionality	– repeatability of PD processes – parallel system design – decomposition in process modeling	– project management – process repeatability – many processes based on product variability and frequency
methods and tools	analytical methods (marketing and patent research, key competencies, risk analysis, cost analysis), deployment of quality functions (QFD), configuration of product options (DFC concept)	simultaneous engineering integrative process, multiple choice concept (DFV), alternative mode and effect analysis (VMEA),	lean, adaptive, flexible manufacturing, product assembly design (DFA), manufacturing design (DFM), diversity reduction program (VRP)
critical success factors	– product positioning – pricing – customer satisfaction – product configuration – performance – product functionality – project team	– efficiency of machines and production processes – processes and quality of execution – core competencies – organizational alignment – project team	– project implementation – logistics – customer feedback
critical points	– functionality – product variability; – product attribute target values – form, configuration and industrial design of the product as a whole, – detailed component design	– deadlines; – project participants; – mechanism of integration interaction; – supply chain – product assembly process – product prototyping	– production plan, launch, – achievement of planned values; – market testing, – launching the product on the market – commercialization

Fig. 1 Methodology for the formation of product systems in mechanical engineering

Complexity	Phase
↑	input (market entry) - in the context of complexity management, limiting cost growth is less important than product differentiation
↓	growth — the focus of the company is shifting towards a rapidly growing market share. As a result, efforts to reduce costs (through economies of scale and the experience curve of effects) are becoming increasingly important.
↓	maturity - the desire to maximize profits and competition reinforce the need for further cost reduction. At this point, product differentiation efforts are less important than cost reduction.
↑	recession - as a rule, expenses are carefully monitored, and investments are at a minimum. When you restart the product or extend the PLC cycle, the manufacturer focuses on the functionality

Fig. 2 Summary of guidelines for managing product complexity based on the PLC cycle phase

Task 1: Determining the complexity of systems (products and processes): identification of complexity sources and factors associated with its growth; quantitative assessment of complexity in a manufacturing company due to increased product diversity.

Task 2: Identify the relationship between product complexity and processes: the problem of the relationship between the complexity of products and processes; the impact of change/creation of a new product on production processes in terms of their complexity growth (1 assumption: replacement at the module and component level in the system improves processes; 2 assumption: if it is possible to reuse part of the elements of classical systems in new projects, this determines a significant reduction in the cost of system design).

Task 3: Achieving the "optimal" level of complexity of the systems: classification/grading of products by degree of difficulty; the problem of achieving optimal operational and financial indicators due to the reduction, preservation, and increase in complexity.

In accordance with the idea put forward, a model of the methodology for the formation of the product development system of engineering enterprises based on the complexity management strategy is presented in Fig. 3.

The proposed methodology for creating a product development system for engineering enterprises based on a complexity management strategy includes:

Stage 1. Product development. Assessing the complexity of the product from the position of the system (Fig. 4).

At the considered stage, the critical indicators of complexity growth are [7, 8]:

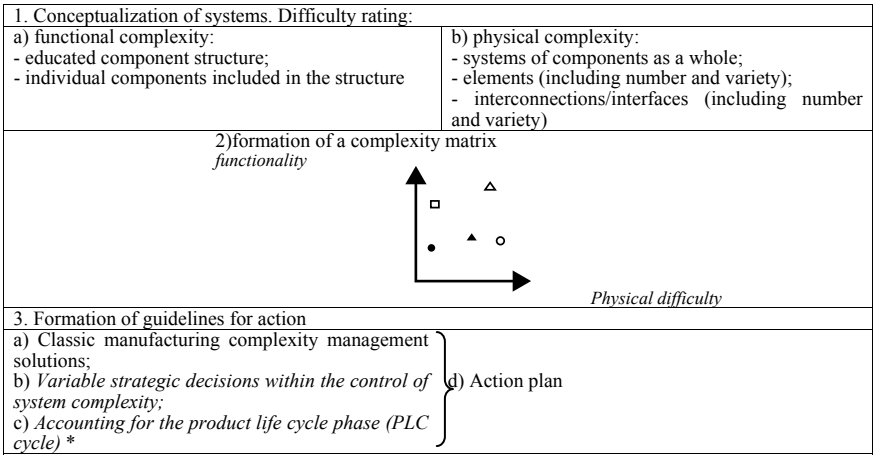

Fig. 3 PD-systems management model in the context of production product complexity control

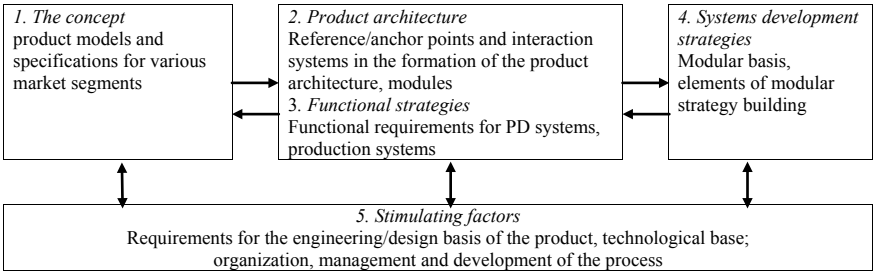

Fig. 4 Content of the product concept

– Unit cost/financial scale of the project;	– The number of alternative components, design, and design approaches;
– Volume of product release;	– The presence of feedback from later to earlier stages;
– The degree of technological novelty;	– The variety of knowledge bases used;
– The degree of IT-support systems;	– A variety of skills and technical resources;
– The number of subsystems and components;	– The intensity of consumer participation;
– The degree of customization of the components;	– Uncertainty due to changing consumer needs;
– The complexity of the choice of product and system architectures;	– – The intensity of the involvement of suppliers in the project

When assessing the complexity are calculated:

- independent components of complexity due to the growth of varieties of products ($C_{product}$), processes ($C_{process}$) and systems (C_{system}).
- dependent components of complexity: $C_{productANDprocess}$ and $C_{productANDsystem}$—complexity of the process and the system, respectively, is due to the growth of diversity at the product level, $C_{processANDproduct}$ and $C_{processANDsystem}$—the problems that arise in the production system due to the growth of process diversity, $C_{systemANDproduct}$ and $C_{systemANDprocess}$—respectively, the level of complexity of the product and the process due introduction of diversity system.

The total complexity is calculated by summing the listed difficulty levels:

$$C_{total} = \sum_{i=1}^{M}\sum_{j=1}^{N} C_{product} + \sum_{i=1}^{K}\sum_{j=1}^{L} C_{process} + \sum_{i=1}^{U}\sum_{j=1}^{V} C_{system}$$

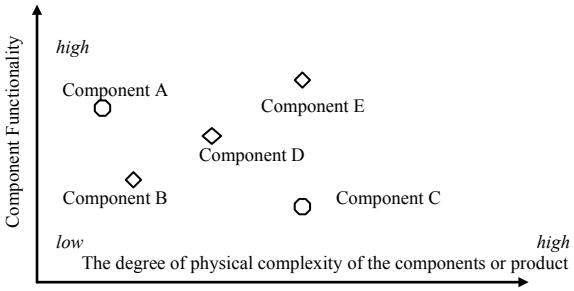

Fig. 5 Schematic representation of the complexity matrix of a product consisting of several components/ elements/ modules * From the picture: components located in the center are more balanced, i.e. their level of physical complexity roughly corresponds to their contribution to functionality

Stage 2. Formation of a complexity matrix (Fig. 5), where:

1. Functional (external) complexity—due to demand, competition and/or technological complexity;
2. Physical (internal) complexity—is determined by: the complexity of the product, determined by a wide variety of raw materials, components, etc.; the complexity of production—the need for a flexible production system; organizational complexity.

The disadvantage of the proposed approach is the impossibility of distinguishing a single functional element for two products, as well as the impossibility of dividing functional elements into two separate functions [9].

Stage 3. Formation of complexity management solutions.

Most manufacturers use classic methods to reduce product complexity, such as [10]:

– replacement of components and product standardization
– inventory management by reducing the number of options stored in stock
– standardization of production processes
– product standardization due to modulation, and standardization strategies.

Based on a complexity matrix and the goal of achieving a balanced system: guidelines for action on managing complexity at the level of production systems and engineering design of a product, in our opinion, can become (Table 1).

At the domestic production level, the strategic options for complexity management can become variable strategic solutions (Table 2):

Research hypothesis requiring further confirmation/refutation: development of product development systems [11, 12] in the context of systems complexity management is possible due to: (1) formation of strategic approaches for the development of production in the context of harmonization of "product-production" systems; (2) simulation of integrated systems and their harmonization—through the integration of production systems and product creation and through the joint development of

Table 1 Set of guidelines for actions to manage complexity of systems

	Guidelines for action	
Product Strategic Decisions	Axis of physical complexity	
	Change in the number of components	– Providing the same functionality with fewer details – Identification and replacement/elimination of individual elements/parts/components
	Changing component diversity	– Determination of the totality of components not conducive to creating customer value for a client – Standardization of individual elements/parts/components
	Fewer interfaces	– Use of several standardized interfaces – Increasing the degree of modularity of the system
	Change the variety of interfaces	– Standardization of interfaces – Increasing the degree of modularity – Input of isolated and/or multifunctional interfaces
	Functionality axis	
	Functionality change	– Adding new features, increasing attractiveness to consumers – Transfer functions between components
	Both axes	
	Combination	– Adding new functions, enhancing the functionality of the system – Shange of product architecture, change of variations in product architecture
	Separation	– Reducing the physical complexity of new components – Enhancing the modularity of the product architecture

(continued)

systems based on: (a) on the primacy of the product model; (b) on the primacy of the process model.

Table 1 (continued)

	Guidelines for action	
Strategic decisions on production, assembly	Change in production strategy	– Product setup (mass customization, customization) – Reconfiguration of the supply chain (in order to increase productivity) – Synthesis of production systems through the use of a joint platform – Joint development of production and product development systems; integration of production and product development systems
	Modifying system specifications	– Improving the technical characteristics of systems through the use of association rules – Formation of a unified product platform and production strategy for production systems
	Changing system configuration	– Multivariate design – Increasing the flexibility of systems, production processes

Table 2 Methods for improving PD systems in comparison with complexity management

Indicator	Production system, engineering design	Operational management, marketing
Strategies for complexity management	– Changing product complexity by replacing product components; changing the architecture of a product, its structure through strategies, modulation, use of platforms – Harmonization of product-production systems – Joint development of production and product development systems; integration of production and product development systems – Formation of a unified product platform and production strategy for production systems – Improvement of technical characteristics of systems	– Identification of the effectiveness of used development strategy – Change, segmentation of production processes (CTO, MTO and ETO) – Change the system configuration network systems; system standardization – The formation of highly effective multivariance of variables of the product architecture – Shange in production strategy

[a]copyright decisions in italics

3 Conclusion

The proposed methodology allows to ensure:

- gradation of difficulty to "good" and "bad", where: first determines the cost increase for both producers and consumers, with increased product diversity, and the second—an increase in the cost of production while reducing the level of diversity;
- acquisition by the manufacturer of structural and functional product diversity in the context of a compromise between a unique product/differentiated product range with relatively high production costs and a unified/standardized product with a minimum product range, but also with minimal production costs.

Deformation Hardening (Sticking) of the Surface Layer and Assessment of Its Characteristics

Vera A. Zotova, Evgeniy A. Semakhin, Zhanna V. Smirnova, Natalia N. Tikhonova, and Anatoliy A. Permovsky

Abstract Technological aspects related to research are considered. For this reason wear of solids taking into account the environment, as well as the effect of lowering their strength due to the adsorption of surface-active substances and energy, which leads to an easier exit of dislocations. The problems of friction of solids are considered taking into account the physiochemical interaction of metals and its structure in the surface layers, which affect the mechanical and technological processes.

Keywords Deformation · Stress · Defect · Hardening · Load · Structure · Metal · Surface layer · Material · Temperature

1 Introduction

All modern structural steels and alloys have a polycrystalline structure. Their strength characteristics vary significantly depending on the correct structure of the metal crystal grid. In contrast from the ideal grid, which until recently was the basis of theoretical calculations of the mechanical properties of the metal. Real grid always has various kinds of defects dislocations or vacancies, etc. The presence of them explains a large discrepancy (hundreds of times) between the values of theoretical and real shear resistance (τ) for various metals. This is clearly shown in Table 1.

Gold	2,620	450	94	0.09
Iron	6,900	1,100	230	2.9

When metals are processed under the influence of external forces and temperatures, plastic deformation occurs in the surface layer, accompanied by further development (formation) and movement (slip) of defects in the crystal grid.

When metals are processed under the influence of external forces and temperatures, plastic deformation occurs in the surface layer, accompanied by further development (formation) and movement (slip) of defects in the crystal grid. This process occurs along the planes of the largest pack of atoms under the action of shearing stresses, when the grid exceed a critical value. With an increase in the degree of deformation, the value of the critical shear stress increases, which is direct hardening. The critical value of the force under which plastic deformation occurs can be estimated by the formula:

$$P_к = 95 \cdot \delta_T^3 \cdot r^3 \cdot \frac{1-\mu}{2E},$$

where δ_T is the yield strength of the processed material; r is the radius of the tool; μ—Poisson coefficient; E—modulus of elasticity of the first kind.

2 Methodology

In order to explain the process of deformation hardening academician A.F. Ioffe put forward the following hypotheses:

(1) During plastic deformation, the slip planes of the crystals deviate from their original shape (the plane $\rho = \infty$) and get some radius of curvature $\rho \neq \infty$. In this case, sliding will be difficult and thus the shear stress will increase, and hardening will occur.
(2) Sliding along any surface violates the correctness of its atomic structure. The surface becomes rough on the atomic scale, and the stronger this part of the crystal is distorted, the greater should be the force that can cause slipping.
(3) Plastic deformation is considered as a discharge of elastic energy accumulated in a single layer. The shift leads to the appearance of two new surfaces with

a destroyed grid. Such surfaces will have a higher potential energy than the original crystal.

Professor A. A. Matalin explains the hardening process from approximately the same positions and adds that hardening occurs by grinding polycrystal grains and creating a deformation texture that reduces the ductility of the metal. At the same time, he explains the second hypothesis of A. F. Ioffe by an increase in the coefficient of friction along glide planes due to small fragments of grains and a change in the shape of crystalline grains that contribute to mechanical engagement [1–7].

At the initial stage (during the introduction), especially at low forces (speeds), plastic deformation occurs in small volumes of metal due to crushing of grains into smaller blocks without breaking the continuity of the metal and the crystal grid inside blocks. In this case, blocks can fit and rotate. With the further development of plastic deformation, new significantly crushed grains smaller than 0.1–0.2 microns in size are formed. The crystals lose their global shape, flatten in the direction of deformation, and formation of an ordered structure of a fibrous nature is possible.

By crushing of blocks into smaller ones, shear deformation begins. The essence of which is the shift of some parts of crystals relative to others along certain planes of the crystal grid with the lowest atomic density. In metals with a cubic crystal grid, such planes are the faces of the cube or planes of the octahedron. At the beginning, shear occurs in crystals whose planes are at an angle of 45° to the direction of the highest stress. A further increase in the deformation forces, plastic deformation begins in other planes and crystals. Shift direction is not constant during deformation, as a result of bending shear planes.

Also sliding within the crystals, which are observed at dynamic loads of the atomic planes. The deformed part of the crystal is relatively undeformed.

The occurring phenomena in the surface layer largely depend on the mode and nature of the deformation, the state and properties of the material of the workpiece, the shape and size of the processing (deforming) tool, and heating temperature during deformation, etc. In this case, hardening depends on the specific stresses and sizes of the contact area between a tool and a treated surface. Deforming stresses increase with pressure. The rate of multiplication of dislocations and other defects of the crystal grid increases, which ultimately leads to more intense hardening.

Increasing the strain rate reduces the duration of the deforming stress. Therefore, plastic deformation due to lack of time occurs in a smaller volume of metal. As a result, at constant pressure, the magnitude of the deforming stresses increases. The latter increases the reproduction rate of dislocations, openings and accelerates the formation of a fine structure, which causes stronger hardening. In this case the thickness of the hardened layer is reduced.

Distortions and other defects of the crystal grid arising in the process of plastic deformation complicate further sliding (shear). In contrast, the thermal motion of atoms helps to reduce distortion and creates more favorable conditions for shear deformation. The effect of thermal motion depends on the strain temperature. As it decreases, the role of the thermal motion of atoms decreases and the resulting hardening increases. With a large degree of plastic deformation, almost all energy

is converted into heat. A reduction in strain distortion at elevated temperatures can reduce hardening.

Hardening during elastic-plastic deformation is a complex phenomenon associated not only with physico and mechanical, but also with chemical structural factors. Thus, during plastic deformation of hardened steels with a martensite-austenitic structure, residual austenite decomposes and becomes martensite. In this case, an additional increase in hardness is observed in the deformed layer, associated with the decomposition of residual austenite. Its transformation into martensite, and the formation of highly dispersed carbides during blocking, which block shear along slip planes. Both types of hardening are superimposed on one another, which leads to a significant increase in surface hardness during hardening of hardened steels.

3 Results

When considering the features of hardening of various structures obtained by heat treatment of steels, the following can be noted. Upon deformation of the sorbitol structure, dispersion hardening is practically absent and hardening occurs due to the multiplication of dislocations. Hardening of the pearlite structure also occurs due to the dislocation mechanism. However, a deformation of this structure is associated with a higher increase in the dislocation density in comparison with the sorbitol structure.

The structure of troostite should be considered as an intermediate state. It is less balanced than perlite and sorbitol. Therefore, during troostite deformation, dispersive decomposition can be observed. Which enhances the hardening effect caused by the dislocation mechanism. In the presence of residual austenite, some effect is possible due to its transformation into martensite.

The deformation of the martensitic structure is accompanied by intense dispersion of hardening and conversion of residual austenite to martensite. An increase in the density of dislocations also occurs. Therefore, in hardened steels, we should expect the greatest hardening effect upon deformation of the martensitic structure and the least upon deformation of the sorbitol structure, which is confirmed by the experimental data presented in Table 2.

Table 2 Increase in surface hardness of knurled hardened samples

Structural state of steel	Hardness gain (Δ *HV*) in steel samples	
	U8	SHX15
Martensite hardening	188	135
Released martensite	120	90
Troostite	60	40
Sorbitol	35	20

The table shows that martensite structures have the largest increase in hardness, and sorbitol structures have the smallest. At the same time, the increase in hardness in U8 steel is higher than in SHX15 steel. Similar results were obtained for other carbon and alloy steels.

Lower hardening efficiency of alloy steels compared to carbon I.V. Kudryavtsev explains by the fact that the residual distortions of the crystal grid resulting from alloying complicate further distortion during plastic deformation.

Considering the physical nature of hardening. It should be noted that in practice, we cannot clearly divide and give preference to any of the above factors characterizing the hardening of parts during plastic deformation. This process is very complicated and has not yet been fully studied. Therefore, it can be assumed that these factors act simultaneously, giving the parts ultimately increased characteristics of strength. Academician A.A. Bochvar pointed out the existing relationship between the number of defects in the crystal grid and strength characteristics. This is shown in Fig. 1, where point 1 corresponds to the theoretical strength of the metal; point 2—strength of single-crystal "whisker" (whiskers of pure iron have a strength of 1400 kgf/mcg); point 3—the practical strength of the annealed metal (the average density of defects in the crystal grid is approximately 10^6–10^8 cm^{-2}); Sect. 4—strength with increasing imperfections in the structure.

A similar increase in strength cannot continue indefinitely: at some point A, the plastic possibilities of the crystal grid are exhausted. It loses strength properties and collapses, i.e. strain hardening. The latter is highly undesirable, since in this case the strength properties of the workpiece are worsened.

The main indicators characterizing strain hardening are the degree and depth of hardening. The degree of hardening is characterized by an increase in the surface hardness of the workpiece.

$$U_N = \frac{H_\mu - H_o}{H_o} \cdot 100\%$$

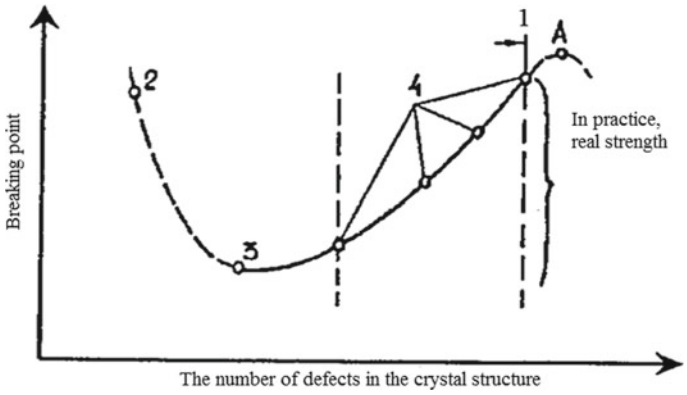

Fig. 1 The number of defects in modern metals and alloys

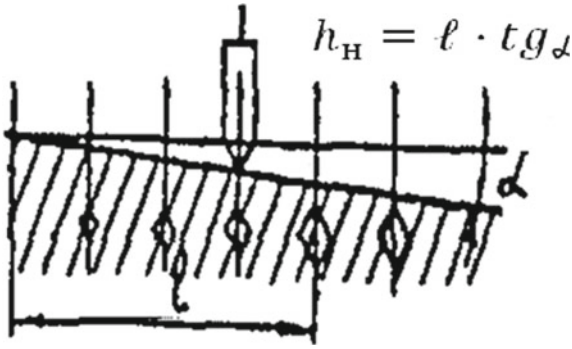

Fig. 2 Microhardness measurement scheme on an oblique section

where H_o and N_μ are the microhardness of the surface before and after processing.

In the case when it is necessary to determine the nature of the hardening propagation in depth, and use the oblique cut method or layer by layer etching. In the first case, a certain metal layer is removed from the surface of the test sample at an angle of 1.5–5° using GOI paste, this minimizes the changes made to the surface layer. Prepared sample is installed on the PMT-3 or PMT-5 device so that the test surface is horizontal. Then, with a diamond pyramid at a load of 10–100 G, imprints are applied (Fig. 2.), their diagonals are measured and microhardness value is determined from tables. Riveted layer ends where the microhardness for adjacent imprints is the same. The depth of hardening is determined by estimation.

In the second case, the surface of the test sample is subjected to etching (often electrical) with the appropriate composition of chemicals with periodic measurement of microhardness.

The advantage of the second option is the absence of any mechanical effects on the surface layer from an indirect cut. In order to assess the surface hardness of soft metals (aluminum, zinc, etc.), and soft galvanic coatings. The sclerometry (scratching) method is used. The test sample is placed on the stage of the PMG-3 device and, after loading it with a diamond pyramid with a load of 10–20 G, moves at a speed of 0.01–0.02 mm/s. The resulting scratch is measured using a microscope and according to the formula proposed by E.C. Berkovich, then microhardness is determined.

$$H_\mu = 3708 \cdot \text{p}/\delta,$$

where p is the load on the diamond pyramid, δ is the width of the scratch. At present, to determine the degree and depth of hardening, the method of X-ray analysis has more often been used. Thin layers of metal 5–10 microns are sequentially etched from the surface and, after each etching with devices like URS-50. After that an x-ray is taken for study. Sequential etching and removal of radiographs allows to clearly identify the hardening of the surface layer, which is fixed in the form of a diffuse ring on the radiographs. With a decrease in the degree of hardening, the image intensity of the ring increases, and the line width decreases.

4 Conclusions

The use of X-ray diffraction analysis allows to increase the accuracy of measurements and to study the boundary between the riveted and the starting metal. Although there is usually no clear interface and alternations of small-sized riveted and non-riveted metal.

Changes in metal layers less than 5 microns thick are not captured by X-ray analysis. In these cases, the surface layer is investigated by the method of structural electron diffraction, based on electron diffraction. Which allows to study the structure of the thinnest surface layer of various materials.

Rational Bureaucracy 2.0: Public Administration in the Era of Artificial Intelligence

Natalia V. Blinova, Artem V. Kirka, and Dmitriy A. Filimonov

Abstract The article reflects research on the dynamics of the process of integrating digital and artificial intelligence technologies in public administration. The authors compared the evolutionary stages of analytical methods and technologies used in corporate sector management systems and in public administration. The analysis revealed similarities that are determined by the key characteristics of modern social processes, which led to the conclusion that the integration of artificial intelligence technologies in public administration is a key condition for increasing the efficiency and ensuring the sustainability of government systems and also the development trend of the public sector in the coming years. An important result of the work is the conclusion that the specifics of public administration, its basic differences from governance in the private sector, lead to deviations from the path of digital evolution that is observed in the private sector. These deviations are objective and they can't be interpreted solely as lag. Public administration as a process of exercising power is based on certain principles, unique resources and proceeds from specific goals. The development of digital technologies, each new generation of which makes the world more transparent, violates the autonomy of the state administration in relation to society, and exacerbates this opposition. The specific data operated by government agencies can't enter the data economy, at least at the present stage: the protection of personal data, tax secrets and other information collected by the state for the implementation of its functions remains the agreed interest of society and the state. The authors propose a model that allows you to get all the benefits from the introduction of digital technologies in public administration, but at the same time maintain state-administrative autonomy. The article presents the key principles for constructing such an adaptive model of «rational bureaucracy 2.0» , which integrates

digital and artificial intelligence technologies into the public administration system while maintaining the immanent autonomy of the public administration system. As the main parameters for developing a strategy for transition and adaptation of the public administration system, the authors justify the classification of functions and tasks for their potential automation based on the principles of rational Weber bureaucracy, which are proposed to be forwarded to artificial intelligence systems, and the staff of government structures will focus on solving complex problems on the principles of network organization, cooperation and proactivity.

Keywords Artificial intelligence · Bureaucracy · Public administration · Digital technologies

JEL I23

1 Introduction

Digital technologies have rapidly entered the life of society and continue to capture new niches, changing organizational and managerial processes, the structure of the economy, and the life of each person. The sphere of public administration is no exception: the words «electronic government» , «online voting» , «portal of public services» have already found their real expression on a par with traditional offline institutions.

Having left the area of the «possible future» , digital technologies confidently stepped into the practice of statistics, state administration, the provision of public services, sociological dimensions and the electoral process. It's impossible to ignore the factor of information and network technologies: they exert too noticeable influence on all systems and processes, changing not only them, but also the behavior and psychology of people. It's likely that we can't yet assess the true scale of the changes.

At the same time, the error price and the bonus from winning have become much higher and overtake actors almost instantly. It's in such an unstable, uncertain, complex and ambiguous world that countries and governments face the same challenges as the private sector, but they are lagging behind in terms of speed of adaptation to changing conditions and the development of technology.

In addition, the specificity of the work of the government system imposes restrictions on the introduction of digital technologies, and therefore requires additional time to adapt and develop approaches that will preserve the autonomy of the state administration, but at the same time optimize the work of the state apparatus, taking advantage of the advantages that digital technologies have.

The object of the study was the strategy of government bodies for embedding artificial intelligence (hereinafter—AI) and other digital technologies in the government process. The authors were looking for the answer to the question of how to

introduce and develop digital technologies in public administration, what principles and models can underlie?

The study is based on the analysis of the adaptation path to the digital technologies of the private sector and a comparison of this path with the dynamics of the public sector. The authors relied on the periodization of the development and diffusion of digital technologies in the private sector proposed by Davenport [1]. This grid was applied to the trend in the development of technological tools in public authorities and administrations in different countries of the world, in terms of officially published results of successful implementation practices.

The main result of the analysis was the conclusion that the development paths for the implementation of digital technologies in the private and public sectors coincided, but certain differences were also identified, which, at first glance, appear to be lagging behind the public administration system from the private sector.

However, the authors substantiate in the article the conclusion that this isn't a lag, but a different model of adaptation to digital technologies, which is caused by the specifics of public administration, its basic differences from private sector management (by purpose, resources, scale, etc.).

The purpose of the article is presenting a model for integrating the public administration system with digital technologies, which allows preserving the autonomy of the government system and its data that require special protection, but at the same time ensuring the level of service and information processing appropriate to the level of development of society and technology. Such integration was named «rational bureaucracy 2.0» , since the authors have proposed the principles of rational bureaucracy of M. Weber. The article presents the results of a study on the applicability of the principles of rational bureaucracy to management models based on digital and artificial intelligence technologies.

2 Materials and Methods

Research organizations' reports on the development and spread of digital technologies in the corporate sector, data on their effectiveness, speed of implementation and transition to a new level from 2005 to 2018 were studied.

Also, the public reports of several governments on the application of digital technologies and technologies based on artificial intelligence in public administration were researched. Successful cases from the USA, Australia, Great Britain, selected regions of Pakistan and Russia were collected and evaluated.

Based on a comparative analysis, trends in the implementation of digital technologies in the private and public sectors were compared. As a result, a general trend in the transition from one digital technology to another was identified, but the public sector lagged significantly. Some of the reasons for the lag were identified, including the ongoing discussion between the scientific community and government officials on the expediency of introducing technologies based on artificial intelligence into public administration, which is caused by the high risks of these technologies.

Another reason for deviations is justified—the specifics of the content of public administration processes and the data that they operate in their activities. Not all data is open, and the public administration system, as a state administrative apparatus, maintains and maintains autonomy. Not all digital technologies and even the stages of digital evolution (according to Davenport) can be reproduced by the public sector for this reason.

3 Results

Understanding public management as a system of society administration, it is important to formulate the requirement of relevance of the subject of management to the object of the managing influence. Therefore, the assessment and forecast of trends in the development of public administration as a subject of management can be based on the analysis of changes that have occurred and are taking place in the subject—in a society, thanks to the spread of digital technologies.

The article presents some proposals for overcoming the resistance to the introduction of new digital technologies in the system of government bodies and substantiates the need for such a transformation, since the risks of lagging in this issue are much higher, according to the authors, than the risks from the introduction.

Based on private sector research, the general principles of developing a strategy for implementing and transforming public administration systems and adapting them to relevant technological advances and methods for ensuring managerial decision-making in the face of uncertainty are derived. Moreover, starting from the principles of rational bureaucracy formulated by M. Weber, the authors described a model for the further development and implementation of digital technologies in public administration.

4 Changing the Environment and the Object of Public Management

The concept of VUCA has been introduced to describe the main parameters of the society (and more broadly—the picture of the world) that is the object of state control [2]. It is an acronym of the English words variability, uncertainty, complexity and ambiguity.

These are the key properties of reality. Indeed, they are characteristics of a two-parameter coordinate system: the reliability of forecasts and the predictability of the results of actions and decisions, as well as an understanding of the initial situation.

The context of modern public administration is the world of VUCA, it's the parameters and borders for management. If the world is different from what it was

when Weber designed his model of rational bureaucracy, it is simply necessary to reconsider the principles of rational governance for a new understanding of reality.

Hence, there comes the requirement of flexibility, adaptability to control systems, which in the described picture of the world become vital. The stability of any control system, including public management, is determined by the competence of proactivity [3].

Traditional discriminative analytics is based on the fact that we have observation data for a certain period, which we can build a trend on, and, accordingly, predict further developments [4]. However, experience has been accumulated showing that further development of events proves to be fundamentally different, even opposite, because over time it turns out that the forecast was not based on all the data or it was the wrong data and factors that actually determined and formed the situation.

Digital technologies have significantly increased the speed of change and thus demonstrated the special properties of social systems. In addition, the merger of social and production control systems in a mixed reality (real plus virtual world) has extended the properties of social systems to technocratic rigid.

As a result, more open corporate structures were able to adapt more quickly to a new understanding and, in fact, formulate the parameters of the world picture more adequately, while a rigid system of public management (not as a reproach, but simply because of the specifics of management tasks).

The conclusion is that there are no more ready-made and unambiguous models and control systems. We have received a different picture of the world, a different understanding of processes taking place in society, and other technologies of management and influence on these processes. These are digital technologies.

5 Change of the Management Model in the AI Era

In 2017, the McKinsey Institute (MGI) issued another survey on digitalization, where it assessed how new technologies, primarily social networks, Big Data and artificial intelligence, are spreading and how they affect the economy, management systems and individual organizations. The experts clearly showed that digitalization has great economic potential for all sectors, but much remains to be discovered. Therefore, it seems that a special role in this process will have to be played by public management bodies, which will have to undergo their own adaptation to the new conditions and new features of social development and structure, since effective management of digital transformation is vital, but it is not an easy task [5, 6].

6 The Evolution of Analytic Models

Thomas Davenport from Babson College analyzed and periodized the evolutionary stages in the development of analytical approaches to digitalization. Davenport identified the following stages in the evolution of digital technology, even giving them the status of epochs [4]. These epochs seem to be important for analyzing the processes of digitalization in authorities, as they provide an opportunity to assess not only the potential of digital technologies, but also the level of their implementation at the current stage.

The first stage was the stage of descriptive analytics. Analytics 1.0. These were tools for visualization of data and their primary processing and grouping, diverse solutions of many developers in the field of Business Intelligence (BI). Advanced flexible reporting, visual and operational.

The next milestone in the evolution of analytics technologies was Big Data—with the appearance of which, or rather, with the appearance of large data processing programs, the next epoch—analytics 2.0 is connected [4]. There was a transition from support of internal decision-making in the organization to work with data as an independent product.

The range of application of this type of analytics is very wide and has not yet chosen its full potential: these are programs that warn about traffic jams, search for documents and laws, control the spread of epidemics, improving the efficiency of public utilities and transport infrastructure, forecasting economic development and so on.

The epoch of Analytics 3.0. appears to have come with the emergence of the so-called data economy [1]. In other words, data have become not just an independent commodity, or a new sector of economy has simply appeared. This sector began to modify traditional industries, enterprises began to digitize and integrate the management model with the data. Some of the control processes have been transferred entirely to the Internet and are implemented in real time, by the flow of continuously incoming data, while other processes are implemented with different levels of automation.

There is a transformation (not just a digitization) of traditional management and traditional industries. Management is becoming a distributed network [4]. Any organization today collects more data than it needs to make internal decisions, but today they can sell this data not as a subproduct, but as part of their complex and distributed system.

This stage hasn't affected government structures yet. Data collected by the state still remains predominantly protected and requires special regulation.

7 Analytics 4.0: The Era of Artificial Intelligence

First of all, let us fix the definition of artificial intelligence to avoid misunderstandings of further explanation. There are several approaches and interpretations, but we would like to dwell on Andreas Kaplan's definition: it is the system's ability to correctly interpret external data, to learn from such data and to use the knowledge gained to achieve specific goals and objectives through flexible adaptation [7].

At the current stage of AI technology development, we are only talking about heuristic tasks: their formulation, setting, development and solution.

Researchers note that depending on geography, from 20 to 30% enterprises invested in AI technologies in 2016 and 2017 [5, 8], and 70% applied at least one AI product in the production process.

The transition of the management system to an AI-based analytics implies further development of databases and statistical methods of their processing along with machine training [4]. The potential of AI can be realized on the basis of Big Data and analytical methods of the first and second epochs (Analytics 1.0 and 2.0). Analytics 4.0 grows from the first and second levels, which are quite actively developed in the public sector. Continuously updated deployed databases and an advanced statistical apparatus are all that is needed to implement AI technologies.

Specialists in the field of AI note that the field of AI application is a creative activity, which involves solution of non-standard and non-repeating problems [9]. The work of almost every intellectual labour worker is ready for some level of automation [10].

Artificial intelligence is not something new for public administration. New technologies have been in the public sector since their introduction. For example, Hila Mehr notes that already in the 90s of the twentieth century public postal services used automatic index recognition to sort letters [11].

The areas where AI technology can find application in public management in the near future are potentially very numerous, as there are many routine operations, data, and regulated procedures. Almost any area of public administration has such a base simply because of its nature.

There are already successfully implemented projects in different countries in different areas of public administration:

- in the USA: automatic provision of benefits, allowances, pensions, migration decisions without a citizen addressing but simply because the necessary conditions defined by law have been met [12];
- emergency call ranking based on urgency (fire service in the USA) [12];
- detection and prevention of the spread of epidemics [12];
- improvement of interaction between citizens and authorities: virtual assistants, chat bots, online forms filling, assistance in finding documents, preparation of documents, making an appointment, etc.

For example, in 2016 in Australia a bot was launched on the website of the tax service Alex, which during the year held 1.5 million conversations on 500 questions and solved 81% of the issues addressed by visitors from the first time [13].

- traffic situation management, prevention of traffic accidents, monitoring of road maintenance, detection of violations of sanitary rules, etc. [14];
- monitoring of social networks of public opinion on current policy, project implementation, and emergency identification and prevention [15].

As it can be seen, the experience in working with technologies is available in state systems and year by year the options and types of projects are increasing. Therefore, it is already possible to make some generalizations, to discover the principles of AI development in the public administration system and limitations. In the authors' opinion, it is very interesting to turn a little bit back to the model of rational bureaucracy of Max Weber, which in many respects is consonant with the requirements that are nowadays imposed on AI systems in management processes.

8 Rational Bureaucracy 2.0: Principles and Transition Strategy

The main characteristic of modern management, as well as its weak point is reactivity. In other words, public management works on the principle of "challenge-response", reacting to incoming threats, events and challenges.

Certain solutions can be obtained by following the evolution in the digitalization environment, by dividing all processes in the control system into repetitive and unique ones. Routines are automated, while the unique processes are left to human teams.

Interestingly, Weber's model of rational bureaucracy is being redefined in the light of digital technology. All rigidity of principles of the hierarchical organization is transferred to automated blocks (potentially subject to automation and AI technologies) [16–19].

It should be specified that a number of principles are implemented simply because of the nature of technology, but there are important principles that need to be adapted. For example, the limitation on the competence and the sphere of management should be transformed into the similar requirement to the system of artificial intellect solving a certain task.

The first priority is to take an inventory of public management functions with regard to their potential for automation. It is the development of automation processes at this level that will significantly optimize the work of the state apparatus.

Hila Mehr in 2017 [11] identified six types of public management tasks and problems in which AI finds its application: resource allocation, data processing, lack of experts, forecasting, procedures, standard routine regulatory operations, data compilation.

Scale and volume of public management tasks implies the necessity of decomposition into small tasks and blocks for gradual automation of processes [4]. Technologies of AI are integrative and can be further united in a uniform system, however, at the initial stage of introduction the strategy should come from necessity to form a certain vector, impulse of transformations [20, 21].

Taking into account the complexity and pace of technological innovations and the growth of the AI market, the strategy for transition to level 4 analytical tools should include a partnership policy. Firstly, program development is not a function of authorities. It will always be a purchase and external order. Secondly, it is necessary to adapt finished products to the needs of authorities and public administration. Thirdly, the partner network allows reducing the risks of contract disruption, getting the best results and guaranteeing the results.

Thus, the principles set out by Max Weber in the first half of the twentieth century, regarding rational bureaucracy, gain a new reading for the era of the fourth generation analytical tools—artificial intelligence. At the same time, the accumulated experience of the private sector in the development and implementation of fourth-generation analytical technologies is of great importance.

9 Discussion

It should be noted that the introduction of AI and any other automation will lead to cost savings for civil service, as part of the apparatus involved in routine work will be released. Nevertheless, the requirements of economy and efficiency are critical and they are applied in all countries to all governments of the modern world. Civil servants will have to solve tasks of a high level of complexity and find creative solutions for non-standard tasks, which demands highly qualified personnel with the set of certain competences.

The main risks are the lack of transparency for the user of the decision-making process, as well as the lack of AI responsibility for the decisions taken.

10 Conclusion

In the context of digital transformation, which has engulfed all spheres of society without exception, the arguments for and against the digitalization of public management in the broadest sense are no longer constructive: from administration, where bureaucratic procedures are most suitable for digitalization and automation, to political management, which seems to be the most responsible and important component of the state's management influence. The transition to digital technologies is an imperative, so governments are faced with the question of how to strategize and manage this transition and how to successfully adapt technologies to the specific tasks facing

the public sector. The evolutionary digital pathway taken by private companies can serve as a basis for developing this strategy.

Organizations that can adapt and integrate AI systems into their management processes will acquire new competencies that will give them sustainability and benefits.

The authors believe that the important goal of this research is to attract the attention of the professional community to the system of public management and political leaders of the states to the development and implementation of management strategies based on technologies of artificial intelligence.

The Era of Digitalization: Philosophical, Social, and Managerial Factors

Viktoriya V. Degtyareva, Dzhamiliya A. Sozaeva, and Zhao Dong

Abstract Today, significant efforts of companies are aimed at collecting and processing information for commercial purposes (using Big Data), assessing consumer choices and behavior (Khayrullina in Bulletin USTU Science Education Economics Series of Economics 4 2004 [5]); Modern Decision Making Technologies in the Digital Economy (Proceedings of the All-Russian Scientific and Practical Conference of Students Graduate Students and Young Scientists, Yurga Institute of Technology, Publishing House of Tomsk Polytechnic University, Tomsk, p. 341, 2018 [7]). Meanwhile, it's arouse the great interest how the management methodologies were transformed (for example, with the implementation of Agile and Scrum) by project teams and labor relations, the process of making managerial decisions and leadership in online, in geographically distributed cross-functional teams and which areas besides market relations and how digitalization has transformed. A study of materials on this subject in open Russian and foreign sources showed that this problem has not been studied enough and is presented only by couple of studies, the most significant of which can be considered only two authors: Sara Pérez-Soler and Savina T.N. The novelty of the study as a whole and this article as a presentation of some of its results consists, in contrast to other studies, in a comprehensive (philosophical, social and managerial aspects) study of the transformation of decision-making processes, social communications and organizational behavior. The article presents the results of a three-year empirical study of the team of authors on the transformation of social, philosophical and managerial aspects of

JEL Code M1

1 Introduction

Nowadays, everybody speaks about digital technologies. Some recognize them a powerful tool that can be used by foreign intelligence agencies, others are afraid of fraudsters who can get access to personal data and bank accounts, the part is sure like in a movie "Moscow Does Not Believe in Tears" (just think, it's 1980) that "our century is full of television and, you know, the TV will replace everything", others are concerned about losing their jobs due to automated production, and the rest is happy about working from anywhere in the world (available Internet gives such an opportunity). Whether we like it or not, but allowing digital technologies to be a part of our lives and participating in their development, we are witnessing the birth of a new philosophy of space and time in the wake of the next scientific and technological revolution. For example, Einstein believed that space and time do not exist without matter and their metric properties are developed by the distribution and interaction of material masses, i.e., gravity. And even today, interaction can take place without the movement of any masses—objects don't move and communicate via the Internet, thereby overcoming time and space [11].

According to Forbes experts and economists, as well as Anton Emel'yanov, head of the United Electronic Trading Facility AO, economic digitalization has affected three groups of relationships:

1. Labor market and labor relations;
2. Business models, including research on the behavior of consumers and competitors;
3. Ethical and legal issues [14].

However, in most studies on digitalization issues and issues, all of these aspects are considered separately, and some issues, for example, making management decisions in the online format, the work of distributed project teams, are studied very little (only [8, 10]) and haven't got enough detail.

In this regard, the authors decided to combine all of the above groups of relations in a single study. The scientific novelty of the research lies in a comprehensive (philosophical, social and managerial aspects) study of the transformation of decision-making processes, social communications and organizational behavior in the context of digitalization. The theoretical significance of the study lies in the formation of a contribution to the theory of management and the adoption of managerial decisions.

2 Methodology

The research methodology is based on methods such as retrospective analysis, synthesis, generalizations, and experiment. At the preparatory stage, the authors have employed the provisions and results of basic (Einstein's theory of relativity) and applied (authors' research and experiments) studies integrated for almost three years and tried out in the framework of international conferences (Step into the Future: Artificial Intelligence and Digital Economy. Revolution in Management: The New Digital Economy or The New World of Machines, State University of Management, 2018), as well as communication with graduate students of the same university specializing in "Management".

3 Findings and Discussions

3.1 Labor Market and Labor Relations

The digitalization of the economy has dramatically changed labor relations. And the changes have touched two levels:

- the global distribution of labor resources
- management in companies

As for global markets, we have seen the outsourcing of production to South-Eastern Asia in the 90 s and 2000s, but now the companies are shifting to unmanned production in Europe, for example like Nike and Adidas in Germany. This situation causes "strong social tension in countries with cheap labor, which get used to the opportunity of employment in large corporations" (Emel'yanov A. Russia 4.0 [3]).

If we speak about approaches to internal governance, it also has suffered some changes. Social networks are now used for making decisions and discussing work tasks and the company's management more closely communicate with employees. It would seem that the above should facilitate and expedite the resolution of any managerial task [12]. But new problems occurred, for example, communication in corporate systems and chats has no sense, there is a lot of spam, and voice messages

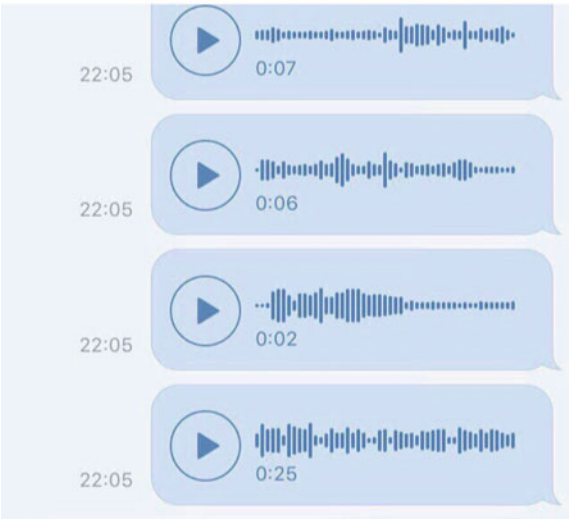

Fig. 1 Discussions in the corporate chat (compiled by the authors using their own corporate chats)

turned out to be the most destructive tool because there is no brief preview option and you need to listen to each message to get a full understanding.

We think that this picture is familiar to many people (Fig. 1):

Within this kind of communication, you can feel oversaturated or get stuck when the participants in the discussion of the managerial decision acknowledge that they "are discussing the same thing" and there are no new ideas [6].

From the psychological standpoint of the decision-making, this stage is regarded as the stage of a group situation modeling and goes before decision-making.

The feeling of "getting stuck at the oversaturation stage" can be explained by a large number of the group, the different rates of perception and examination of information by participants making decisions, etc.

For keeping the sense of the discussion, the scientists developed intelligent bots that trace the thread of conversation in corporate chat using keywords, and then help to know what decision has been finally made. For instance, Sara Pérez-Soler in the article "Collaborative Modeling and Group Decision-Making Using Chatbots Within Social Networks" talks about the SOCIO application and how it helps you trace the path of conversation (Pérez-Soler, S. et al. Collaborative modeling and group decisionmaking using chatbots within social networks, 2020 [8]) (Fig. 2).

But in fact, bots are not a cure-all. When I together with my colleagues conducted the experiment "Cognitive Peculiarities of Decision-Making in the Digital Economy" in December 2018, it seemed to us that decision-making via different kinds of chats is several times slower than at regular meetings, which is proved by graphs and analytical data within the experiment. During the experiment, the participants were divided into three groups with 6 people. By turn, each group was asked to solve a particular case that generally implies multiple options or making up a priority list of answers. Case assignments were prepared with using Richard Thaler's developments

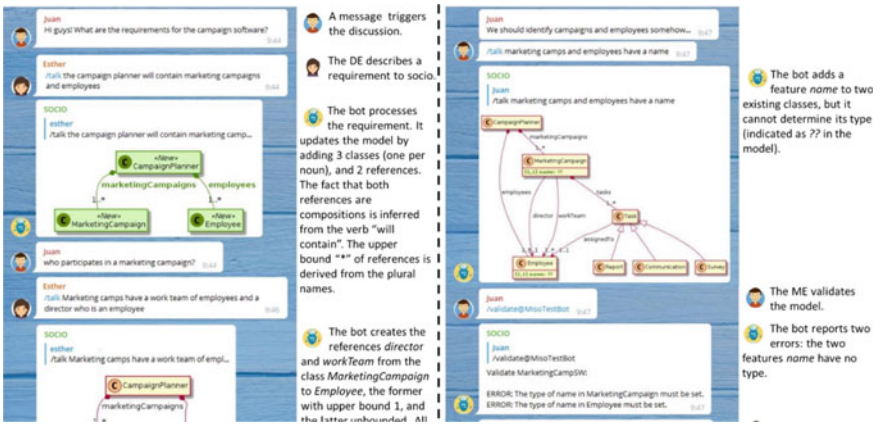

Fig. 2 SOCIO application and the principle of its operation (based on the study by Pérez-Soler, S. et al. Collaborative modeling and group decisionmaking using chatbots within social networks, 2020 [8])

in behavioral economics [13]. The teams solved each of the cases in different ways (by brainstorming and discussion, by brainstorming without discussion, and via social networks or instant messengers at their own choice, as well as using the Mentimeter application for anonymous voting and selecting options from the suggested list). Everyone can find a description of the experiment in an earlier published article. The authors believe that "experiments can they should be continued for a more detailed study of the cognitive features of managerial decision-making". (Degtyareva, V.V. et al. Cognitive features of managerial decision making in the digital economy, 2020 [2]) (Fig. 3).

Later, in 2019, we repeated the experiment three times under the same conditions and with the same initial data, but in different groups. One time of the four cases, the conventional decision-making at the meeting and brainstorming has been inferior to

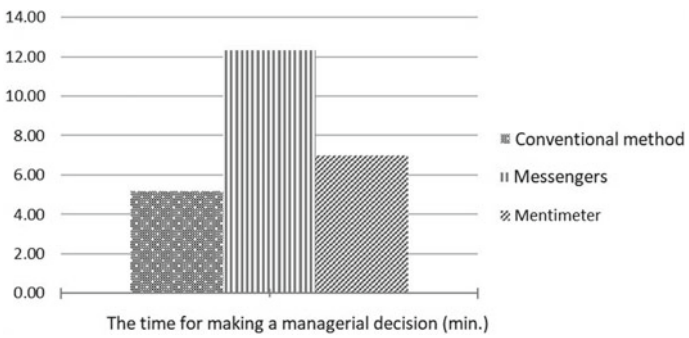

Fig. 3 Speed of making managerial decisions using various methods, experiment 1. *Source* Degtyareva [2]

Table 1 The results of the experiments (compiled by the authors)

Parameter	Experiment number	Conventional method	Messengers	Mentimeter
Decision-making time (min.)	1	5.17	12.33	7.00
	2	3.00	15.00	4.50
	3	2.33	10.47	6.00
	4	9.49	7.67	5.25
The performance of decision-making	1	Made	Made	Made
	2	Made	Made	Made
	3	Made	Made	Made
	4	Made	Made	Made
The presence of the leader	1	Yes	No	No
	2	No	Yes	No
	3	Yes	Yes	No
	4	Yes	No	No

instant messengers in terms of speed. As for leadership, in all cases, the situations were much different that it turned out to be impossible to reveal the pattern of the leader's presence/absence during conventional decision-making and messenger type. As for the Mentimeter application for anonymous voting for one of the suggested solutions to the problem, it stably showed 5–7 min in the situation without a leader (since the leader has not been personified) (Table 1).

Also, pay attention that the "stuck effect" is so evident in decision-making via messengers. On average, it is 3–4 times slower than in personal communication and 1.5–2 times slower in comparison with voting.

We don't know, this is advantage or disadvantage but the use of social networks for decision-making has yet to be assessed, but there are risks that, for example, the role of the department head will be greatly reduced, since more close relations between the specialists of different management levels via corporate communication systems allow dropping messages to a director in Telegram at any time.

3.2 Transformation of Business Philosophy and Models

As for business models, this area is a pioneer of digital transformations, and the banking sector can be surely called a leader. Back in 2005, students were told that there is some quasi-money (some kind of electronic currency), and today, in just 15 years we can pay for anything online and cryptocurrency has also appeared (it's the very conditional electronic money using which we can buy a limited range of goods yet, but as a matter of fact, they exist). In some countries, digital technologies have made a dramatic revolution in the banking sector. African countries with a pretty high level of development have skipped the stage of electronic cards (bank

cards), ATMs, and, thanks to the availability of mobile phones and online stores, can make purchases using applications by direct debiting of money from a mobile phone account and bypassing banks. However, as noted in various studies, the European population follows the conventional method. The chain Bank cards—ATM—stores is a bright example of that digital technology has dramatically changed the idea of the tangible component of goods and money turnover.

In general, business models today make a fantastic breakthrough in predicting and analyzing consumer behavior; choosing, advertising, packaging, and supplying products, etc. Without leaving home you can buy any product, and, knowing the search queries of millions of people, manufacturers and sellers are ready to offer you the product or service you need. On the slides, there is some information about the matter of things in the B2C field that is, for all of us (Figs. 4 and 5).

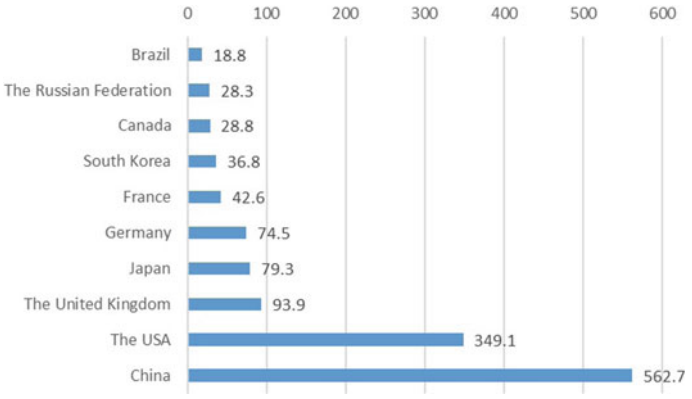

Fig. 4 TOP-10 countries by capacity of e-commerce markets, billion US dollars [15]

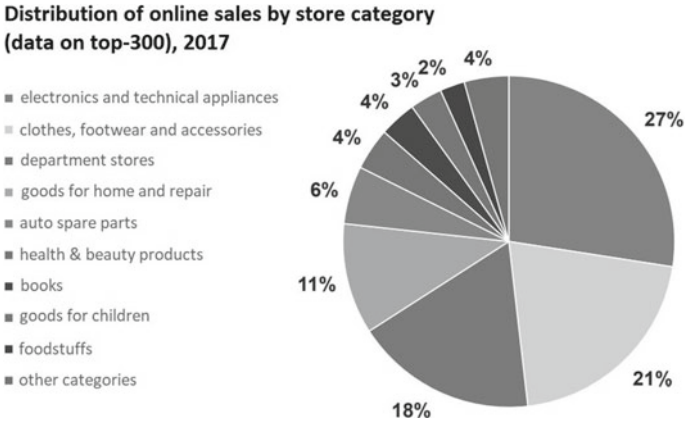

Fig. 5 The structure of the e-commerce market [4]

According to Data Insight, both average cost of purchases and their number is actively growing in the Russian e-market of tangible goods.

A typical market consumer is also described: individuals of 25–34 years old with sufficient experience in online purchasing and above-average income.

3.3 Ethical and Social Factors of Digitalization

The existing social factors of economic digitalization have both negative and positive impacts.

Ten years ago to the day, people were afraid of digitalization and the transition to a "smart economy". Social scientist Andrei Ashkerov in an article "Smart Economy" published in "Russian Journal" said that ""smart economy" is not broadband Internet (it's really so), it puts an end to the intelligentsia (here the stand is not clear-cut) and triggers the consideration of the relationships between social classes and groups, therefore a "smart economy" is impossible (this thought is also unclear) without the transformation of social consciousness" (Ashkerov A. Smart Economy, 2020 [1]).

According to forecasts of the past ten years, the aggressive development of technology should have resulted in the emergence of a new medium, the Internet of Things, when inanimate objects become full-fledged units of social communications. For example, your printer will send information to the factory or store in the need of new cartridge, and the car will book the day and time for routine maintenance in the service station because the term has expired.

It is interesting that in Russia we can find examples of not so sophisticated but the progressive movement towards the introduction of the Internet of things in the city of Moscow. Let's look at the development path of the Internet of things (4 main stages) and our capital. We have a single Wi-Fi network, the opportunity to quickly inform the residents and collect their opinions via the application "Aktivnyi Grazhdanin", a single transport network, and so on. Of course, we are far from the rise of machines, but what we see outside the window, around the city, in the universities (simulation models of patients who indicate students at their mistakes and die before their eyes), in stores, in the car-sharing system is impressive!

In the opinion of Rob Van Kranenburg, the Internet of Things is a "four-layer cake" [9].

Level 1 is associated with the identification of each object.

Level 2 provides service to satisfy the consumers' needs (it can be called a network of your own "things", a particular example is "smart home").

Level 3 is related to urbanization. This is the concept of a "smart city", where all the information about the residents of this city is collected in a specific residential quarter, in the house of yours and your neighbors.

Level 4 is a sensory planet.

Bearing in mind the 10-year-old speculations by Andrei Ashkerov, we should note that by the summer of 2019, many issues related to the introduction of the digital economy have also changed. The intelligentsia has become even more demanded:

engineering personnel, specialists biotechnology, and other related fields have turned out to be necessary for the economy. Public consciousness has changed too. For example, beggars in the center of Moscow on Myasnitskaya street told us that if "sir doesn't have cash, then he can easily transfer alms to the card of Sberbank, VTB, Alfa-Bank, and even Tinkoff", immediately gave the card number and made sure that the operation has been completed.

4 Conclusions

An analysis of the social and managerial factors of digitalization shows that the introduction of digital technologies has dramatically changed the communication, and may have slowed down managerial decision-making. Decision-making and managing via social networks takes on average threefold time than within the face-to-face brainstorming sessions, although it is not linearly related to the presence or absence of a leader. Social issues of digitalization such as changing structure of the labor market, professions, the transformation of established social groups and classes, in our opinion, is the subject-matter of more time-intensive and thorough study. The study of social issues can be considerably adjusted by a sample of the urban population, megacities (here the shifts will be more noticeable) and small cities (not clear-cut for making reliable conclusions).

The Phenomenon of Balanced Economy in the Context of the System Paradigm

Zoya D. Denikina and Anatoliy V. Denikin

Abstract **Purpose**: The purpose of the study is to explicate the concept of economic balance and sustainable development in the problem field of the philosophy of science, interdisciplinary knowledge, and the interface of system paradigms in the evolution of economic theory. **Methodology**: The key research method is the system paradigm. At the same time, the system paradigm has degrees of gradation that lead to different epistemological results. **Findings**: Indicators of system balance in the mechanistic and organic interpretations of economic life are Revealed. It is concluded that political economy is relevant for the classical explanation of certain types of supercomplicated economic States. Special attention is paid to ontological situations described by non-classical science, when the phenomenon of balance is revealed through the interaction of subject and system meanings. The authors project the system doctrine of N. Luman on the desired subject area of economic theory. To explicate the phenomenon of economic balance, the system-system and system-external environment relations are conceptualized. Put forward the position that current trends of economic growth and sustainable development involve three types of States economic system (national economy), with indicators of intersystem interactions (Economics of law, Economics of education, etc.) with the state of the environment (geopolitical controversies, global processes). **Originality**: The Originality of the author's concept is to identify the subjective and objective meanings of economic balance. For this purpose, economic behavior and systemic institutional effects are considered within the framework of non-classical and post-non-classical philosophical and scientific thinking.

1 Introduction

Currently, the terminological vocabulary of economic theory is adapting to general scientific concepts (order, chaos, self-organization, self-regulation, structural properties, paradigm, stability, systemicity, etc.), to philosophical categories (development, evolution, essence, form, progress, measure and etc.) and to the concepts borrowed from socio-humanitarian knowledge (behavior, motivation, risk, adaptation, dysfunction, etc.). As a result of a long correlation of disciplinary, interdisciplinary [6] and superdisciplinary knowledge, the problem of a paradigmatic review of its results is being actualized. Reflections on the development of the economy in general, on some kind of abstract growth or regression are epistemologically unproductive. It should be clarified in what interval of abstraction the research position is and from what key ideas about economic being and the methods of its explanation are dependent.

It is hard to disagree with the statement that "today there is no other branch of science and knowledge where the measurements would be more contradictory, estimates are necessary, and the results are simply unsuitable for practice than in economic science… The apologies are associated with the incredible complexity of economic objects and systems… and are insufficient to maintain and recognize the current state of affairs as unchanged" [17].

Authors who study the systemic balance of the economy point to the systemic paradigm of J. Kornai [9]. The sphere of system research, based on the external stability and integrity of the system, was called the new theory of economic systems [10].

2 Methodology

From the point of view of the philosophy of economics, the term "systemic balance" goes back to the mechanistic and organic interpretations of reality. According to the first one, the whole is equal to the sum of the parts, causal-and-effect automatism operates therein, each element of the system is an indivisible, simple in its essence thing (investment projects, budget revenues, enterprises, etc.). In such a whole, the system space is homogeneous (the main premise of I. Newton's concept), system processes are reversible, since they obey cause-and-effect relationships. In this case, the cause is interpreted as a force effect which is external to the effect. Accordingly, any component of the mechanistic system, being in the same type of space, necessarily functions in a state of balance. In this case, the balance means the presence of a sufficient number of elements that allow reduction, reduce complex things to simple, isolate the invariant types of interactions between elements of the system. The balance also indicates the essential uniformity of the elements between which the necessary cause-effect relationships arise. For example, increasing the stability of the domestic food market as a result of external sanctions pressure cannot be considered as a mechanism for reproducing a balanced economy.

According to the second point of view, within an organic system the whole is greater than the sum of the parts in terms of quality and is equal to it in terms of quantity. Now, the balance is studied not so much in the abstractions of interaction as in terms of natural development. According to Hegel, the cause is the essence in action, and in this sense, the balance means that part of the organic system (for example, investment) really contains the ability to affect (substantial reason) another part of the system in the way, which causes qualitative change in its state (for example, raising the level of development of mining industry).

Organistic systemic views are present in Marxist political economy, which revealed the interconnectedness of the foundation and substantiated things within economic and social life. Their interrelation reflects strict linearity, one layer reflects the necessary stability, and the other reflects the necessary variability, in which the essential features do not disappear, random meaningful changes carry the essential specificity, acting as a projection in relation to the foundation (this is the relationship of productive forces and production relations). The superposition of these projections results in the third, synthetic dimension, thanks to the dialectic method, the dynamics of changes can be traced. Sustainability of development means the impossibility of a given dynamics moving to the frameworks of another systemic measure. In the classical paradigm of an organic type, balance indicates the fact that any economic phenomenon, despite its seeming unity and inconsistency, bears signs of a common essence. The phenomenon is not autonomous, it is subordinated to the determination of a foundation-substantiated and essence-phenomenon.

Organic balance differs from the mechanical one in that there is a systemic determination in it. Thus, capitalist's profits cannot be adequately explained by the revenues from land rents that flourish in feudal society. According to the classical paradigm, in the capitalist mode of production there are two types of markers: an invariable basis and variable content, which necessarily appear in the current dynamics of events. Within the development, inherent indices of balance are continuously reproduced.

Are the postulates of Marxist political economy acceptable for modern economic theory? The answer is both yes and no. Marxist political economy includes economic life in political relations in such a way that this context does not refer to the status of conditions, the background of economic events, but has the status of a sphere of activity dependent on the economy. The emphasis on the consideration of areas of public life should be objective. Until we find out what capitalist relations are, our activities are doomed to subjective and voluntaristic consequences. The researcher in the classical paradigm works in conditions of certainty, essential transparency. He is free not to focus all his attention on the environment which is external in relation to the whole, because the whole, according to Hegel, is an objective expression of the essence, and the essence in its natural existence cannot be deformed. The necessary processes of change or the processes of natural violation of the measure are fixed.

A modern researcher understands that political economy is a fragment of the concept of explaining extremely complex economic conditions, when environmental dependencies are weakening within the economic reality, and a radical change in conditions is temporarily suspended. On the agenda there is the task of establishing

and maintaining this type of essence (for example, the parameters of the national economy). There is a moment of prevalence of the essential determination of the classical type, to which all other types of dependence are subordinate - managerial, structural, functional, etc.

The criterion for assessing the sustainability of development is the time of dominance of the essential determination. Development criteria indicate the emergence of an increasing number of economic phenomena manifesting the desired essence. The space and time of economic life become homogeneous and are set by the guidelines of the national economy. Any project efforts, organizational transformations, ultimately, reproduce the systemic whole. According to such political and economic views, the economy operates at the meso—and macro—levels sufficient to describe stable states.

Modern systemic theory refers to the explication of phenomena that are not part of the problem field of the classical paradigm. A return to the political economic abstractions of sustainability and balance is currently possible in two epistemological cases. Firstly, when explaining economic life in a given system of conditions, when an non-causal determination (the effect of conditions) is combined with essential determination (for example, the effect of organizational structures and financial resources of the BRICS countries on national economies).

Secondly, when explaining the transition of the economy from crisis to recovery, finding an attractor and further weakly nonequilibrium state. In this case, not only the constructive activity of the economic policy of the government and the expert community is taken into account, but also the logic of the development of the emerging system itself.

The type of ontological situations described by non-classical science—the complementarity of the system to the internal conditions of its existence—should be specially designated. It seems that this type of economic condition was actively studied in the period 1960–1980s. In so doing, the system was defined as a complex interconnection of elements, that is, without classical ideas about the dependence of the substantiated on the basis Anokhin [1], Bertalanffy [2, 3], Blauberg and Yudin [4], Boulding [5], Druzhinin and Kontorov [7], Fleishman [8], Lectorskiy and Sadovsky [11], Mesarovich and Takahara [15], Rapoport [16], Uemov [18].

3 Results

Modern systemic economic research is faced with the problem of translating subjective and systemic meaning, systemic and non-systemic meaning. When adopting the motives of economic behavior as a determinant, subjective "tension" persists, and, as it is known, institutions are of a systemic nature and growth criteria are also systemic.

Defining systemic meaning as a constant reduces the effects of uncertainty. Firstly, systemic meanings are super-subjective and rational, they constitute the unity of economic reality. Secondly, in post-nonclassical knowledge, uncertainty is often identified with the range of possibilities in the evolution of the system, which are

found in the attractor pool, within the framework of the proposed system solutions. In this case, the uncertainty parameters become rational. Thirdly, the mechanism of self-observation of the system appears as the generation of systemic meaning. Such a mono logic, on the one hand, opposes the voluntarism of managerial decisions, and on the other hand, the multiple meanings of the world (alternative political strategies, legislative shortcomings, etc.).

The outstanding German sociologists N. Luhmann turns to a new kind of holism in the description of systems. "The *whole/part* scheme is rooted in the old European tradition, and if applied here, it will not have a defining point… Rather, each particular system reproduces the encompassing system to which it belongs, through its *own… differentiation between the system and the environment*" [12]. It seems that such a system ontology is designed to neutralize the illogical semantic influence of the environment opposing the system and its surrounding world. Luhmann does not call the distinction between the system and the surrounding world an ontological boundary, but, apparently, in the case of the external environment, we are dealing with ontological reality.

When projecting the Luhmann's theory on this subject area, the external environment can be understood as a social space that is not a part of the surrounding world of the system. The environment is not of the same order with the surrounding world because it is not constituted by systems as such. Unlike the surrounding world, the external environment does not provide the opportunity for private systems to form unique systemic meanings. The external environment is involved in the constituting of systemic meanings as an environmental background and operating conditions. At the same time, it can affect the system in a specific way, trying to radically change the system code and system meanings. Similar scenarios are described in synergistic studies.

The specifics of the current moment is that the modern economic system is in a highly non-equilibrium external environment, and this circumstance needs the closest research attention. The environment is not the boundary of distinguishing a system, but an active factor, a powerful determinant that affects the behavior of systems and their surrounding worlds. The external environment, by definition, is more complex than the surrounding world because, as a rule, it is highly non-equilibrium. As a result, categorical synergetics are productive for describing both the system and the external environment.

Communications taking place in the external environment, are of a different kind than those pointed out by Luhmann. It is significant that for inter-system interaction, Luhmann uses the concept of integration, and for intra-system communications - the concept of unity. "In this understanding, integration is not a value-loaded concept, and it is not "better" than disintegration. Moreover, it does not correlate with "unity"… of the system (… integration may be more or less, and unity cannot be more or less). Therefore, integration… does not depend on the "obedience" of individual systems to central levels. It consists not in the connection of "parts" with the "whole", but in the mobile… adjustment of individual systems in relation to each other" [12].

It seems that the external environment does not contain guarantees of rationality and cannot be described in terms of a self-referential, self-organizing global system.

If the external environment calls into question the stability of the existence of individual systems, including economics, then, apparently, the subjective consciousness "expelled" by Luhmann to the outside world acquires an external, inter-systemic function to minimize the influence of strongly non-equilibrium states. Country leaders, heads of parliaments, corporations, the general public can generate ideas and take actions to neutralize the effects of the destruction of their own world of systems (according to Luhmann, the intersystem activity of subjects is a form of integration).

The relations system-system and system-external environment are problematized as a subject of study of institutional theories and concepts of economic behavior. The stabilizing role of institutional forms of inter-system interactions is noteworthy. In many ways, they have a contractual nature, so successfully studied by J. Habermas in a pragmatic discourse. According to Luhmann, the subjects of the surrounding world of individual systems do not come to agreements on intra-system meanings, economic characteristics acquire economic nature only in the economic system itself. Their code cannot be dual, depending, for example, on political predilections. Systemic meanings are conventional only in the sense that the information circulated in the system becomes communication if the communicated message is understood. Thus, the awareness of the need for economic growth is not explained solely by departmental or personal preferences, but acts as a systemic solution. The same event is differently identified in various individual. "… The legal act of introducing the draft budget will be something different than an occasion for news and comments in the media; it becomes different as a political symbolization of consensus and disagreement; and finally, it becomes different in terms of to what the exchanges react". "… Integration issues are a form that highly complex societies are developing to be able to manage the processes of dependences and independences between several individual systems simultaneously" [12].

Modern trends of economic growth and sustainable development are associated with three types of states of the economic system (problems of the national economy), with indicators of inter-system interactions (economics-law, economics-education, etc.), with the state of the external environment (geopolitical contradictions, globalization and de-globalization processes). In the language of system analysis, an indicator of the stability of an economic system is its ability to self-observe and self-organize. Another type of observation is carried out in inter-system interactions. "A system… cannot quickly cross its own borders… but it can observe, that is, to indicate which specific state of things (here: other systems) are relevant for the system in a specific way" [12]. It seems that the indicator of the state of the external environment is the transformation of its cause-effect relationships and functions during the transition to the interval of strong non-equilibrium.

In the economic policy of the state, it is necessary to consider both of these scenarios. The difficulty lies in the fact that they are not the result of an analytical choice from the possible positions of economic growth. To a large extent, they have already been preset by economic analysts as constants. Further modeling of the national economy during the period of non-equilibrium geopolitical realities is a systemic task, featuring both known and unknown conditions. Only at first

glance management decisions look of the same type, corresponding to unambiguous modeling. Their algorithm is different and is determined by the differentiation of the system and the surrounding world.

Let's illustrate the operation of the first algorithm, based on the ideas of the system theory by Luhmann. Management decisions, that is the actions of subjects, are localized in the surrounding world. In fact, for the economic system they serve as matter, the substantive basis for conducting system operations. Management decisions are situational. "The combination of politics and economy is achieved primarily through taxes and fees. This does not change the fact that any disposal of money occurs in the form of an economic payment. But such an order can be politically conditioned and in this case is not profit-oriented. Consequently, the goals of using the state budget are a political issue… But the use of money itself is subject to the market laws of the economic system… and if the "share of the state" in money circulation increases, this has significant consequences for the structural development of the economic system" [12].

Management decisions can also be included into the message flow for the economic system; in the future they circulate as information (unproductive functioning), unless the system selected them as significant economic meanings. Only those management decisions that correspond to the economic nature and current situation become systemic communications. In other words, a self-referential economic system "rejects" inadequate management decisions.

Another management decision algorithm is related to the external environment. This ontological case has not been sufficiently studied in economic theory, philosophy of economics, and interdisciplinary knowledge. The vector of managerial decisions of this kind is ambivalent; it is directed both toward the economic system and toward the environment. With regard to the external environment, subjective bearers from different systems (economics, politics, science, law enforcement agencies, etc.) can afford active constructive activity to transform it.

It seems that the surrounding world is needed by the system in order to selectively treat the external environment. The coherence effect is achieved as a result of the interaction of actors from different surrounding worlds. At the same time, there is a double coherence: in relation to inter-system interactions and in terms of bringing the components of the environment into a slightly non-equilibrium state. The observation of the external environment depends on the competencies of the subjects.

4 Conclusions

From the post-non-classical thinking standpoint, another ontological moment is included in economic behavior. Due to the interaction of subjects from the surrounding world, cyclic causality is carried out between the system and the external environment, and possible feedback is established in an operationally closed system.

On the other hand, the economic behavior of subjects is associated with the reflection of the economic system itself, and in the case of managerial decisions - with the subject component of the target causality.

Systemic descriptions of the economy are to a certain degree close to neo-institutionalist views. As it is known, the focus of the new institutional theory is on the determinative influence of institutions. Refusing the postulate of a free market economy, neo-institutionalists study the systemic effects of transaction costs. At the same time, the institutes themselves act as products of social development.

The systemic concept of the Luhmann model indicates more fundamental causal and functional dependencies. At the epicenter of determination there is the "code" of the system, which itself does not depend on anything and is not controlled by anything. Its availability in the system determines the transformation of institutions and material structure, there is an economically sound choice of rational behavior.

For the national economy, the system-forming axis is not the opposition of a free or regulated market, although it is relevant on the agenda of economic science, but the procedure for identifying events, according to the code of a "clear economy". In a social life where everything is intertwined, legal, political, ethno-cultural and other management mechanisms are applied. However, the real picture of economic activity is that these mechanisms fall into the position of dependent structures, consolidated by economic senses, and in the system they are forced to "play" according to the rules of the economic code. Otherwise, their intrusions from the outside leads to essence and information asymmetry. Internal effects appear in the system, claiming to be the basic structure, but in reality they are a "virus" that erases the meaning of system unity. Such effects differ from the usual anomalies circulating in the system. To give an example of Luhmann: "A constitution can be adopted as a legal text, but it does not function if it cannot cope with the unconstitutional influences of political power on the legal system, for example, in the police field or in the widespread form of corruption" [12].

The economic code is adequately articulated in well-known formulas: "economics are the laws of the production of social wealth" and (and not or) "optimal solutions in conditions of limited resources". Deviation from this code will mean:

- temporary functional dependencies operate instead of laws-trends;
- production is lost or replaced by another form of activity;
- other things, but not social wealth, prevail;
- the meanings-simulacra begin to act in the system;
- the system has not just limited resources, but extra-systemic means alien to the system;
- instead of optimal solutions, measures of an unsystematic nature are applied.

Modern economic science is faced with the need for a thorough analysis of economic "pseudo-reality", which does not coincide with crisis manifestations. Strategies and forms of economic balance, sustainable development are problematized only in a truly systematic perspective. The system constitutes itself internally, with respect to its own operations and decisions, and externally, with respect to the determinants of the external environment.

At one time, K. Marx introduced the term "vulgar economy" into the terminological circulation. By the latter, he understood the consideration of external dependencies and a description of the most rude phenomena of economic life [14]. Of course, A. Marshall is right, pointing out that "we must keep constantly in mind the history of the terms which we use… this history is important for its own sake… it throws side lights on the history of the economic development of society" [13].

The explication of the concepts of economic balance and sustainable development is associated with the evolution of economic knowledge and with a change in the conditions of economic activity. It becomes clear that the abstraction "systemic paradigm in economy" is embedded in the problem field of the philosophy of science and interdisciplinary knowledge. In this situation, one of the tasks of economic science is to develop a concept for interfacing various system paradigms in order to increase aggregate knowledge and determine practical recommendations for ensuring balance and sustainable development.

FDI from the United Kingdom in Latvia Under BREXIT Factor

Andrejs Limanskis

Abstract The importance of the research is based on avalanche of news concerning BREXIT in general and concrete countries situation. British investors prove traditional interest in Latvia as recipient economy, United Kingdom being the 10th in the list of top foreign investors. Partisans of sustainability investment however have grounds to doubt the positive impact of the UK FDI in Latvia in the last three years. Unfortunately, no research is published on UK FDI in Latvia. Thus, the research is topical. The aim of the research is to investigate the flow of UK FDI in Latvia in 36 months after the BREXIT referendum in order to disclose how the change of political vector has affected the FDI process in Latvia. Author employ both qualitative and quantitative methods of research. Qualitative methods include literature review, personal observations and experts' interviews. Time series analysis as well as charts plotting represent quantitative methods. The time series for analysis consist of non-financial and financial indicators of the UK FDI in Latvia. In the further research, questionnaire would be recommended. However, it proved not possible in the time of this investigation. The hypothesis to be proven is as follows: after the BREXIT referendum, UK FDI in Latvia measurably declined. The novelty consists of singling out the BREXIT factor in the dynamics of the UK FDI in Latvia and evaluating the corresponding gain or loss, if any, in euro. The figure can be introduced in the scientific circulation.

Keywords Corporate cross border mobility · Foreign direct investment · United kingdom · Latvia

1 Introduction

According to [4], editor-in-chief of renowned *FDI Magazine*, the UK has rebounded somewhat from the dramatic drop in inward greenfield foreign direct investment (FDI) that was experienced immediately after the referendum to leave the EU in 2016 but nonetheless witnessed a second year of decline after previously being among the world's most reliable FDI performers. Access to markets and the UK's future trade arrangements are top of the list of the uncertainties impacting UK FDI, outward FDI flow being an important issue as well.

The BREXIT referendum was held on 23 June, 2016, to decide whether the UK should leave or remain in the European Union. Leave won by 51.9% to 48.1%. The referendum turnout was 71.8%, with more than 30 million people voting. No doubt, results of the referendum exerted pressure on decisions of potential UK investors whether to invest in Latvia, the EU member state since May 1, 2004.

Corporate mobility across borders shows uncertainty in dynamics. Contrary to expectations by many experts, the corresponding activity after BREXIT referendum shows decline due to a number of factors.

The third anniversary of BREXIT gives ground for asking questions on its impact in the sphere of foreign direct investment (FDI) both globally and for specified economies. Author leave the global aspect to better-equipped research institutions like FDI Intelligence, the Financial Times' specialist unit dedicated to FDI. However, for Latvia, the effect can be investigated since there is reliable FDI monthly statistics that can counteract with opinions by local experts and personal observations.

The importance of the research topic is based on traditional interest by the UK investors in Latvia as recipient economy, United Kingdom being the 10th in the list of top foreign investors. Partisans of sustainability investment have grounds to doubt the positive impact of the UK in Latvia in the last three years. Unfortunately, no research is published on UK FDI in Latvia. Thus, the research is topical.

The aim of the research is to investigate the flow of UK FDI in Latvia in 36 months after the BREXIT referendum in order to disclose how the change of political vector has affected the FDI process in Latvia.

The reliability of statistics is high since registration of FDI deals is vested on the Register of Enterprises of Republic of Latvia and in turn made accessible for researchers by Lursoft. Reference to Lursoft, the company providing access to FDI statistics is obligatory and the Author does it with gratefulness.

The hypothesis to be proven is: after the BREXIT referendum, UK FDI in Latvia measurably declined.

The idea is to disclose FDI dynamics in Latvia from all donors in general for the period and to employ benchmarking of the UK FDI in Latvia against the general. Thus impact of BREXIT referendum on the UK FDI in Latvia can be measured. Month-on-month analysis is not as common as the typical yearly data series one. Methodologically, the gap between them is to be bridged in this research. Loss, if any, of UK FDI in Latvia due to BREXIT referendum can be evaluated for scientific circulation.

2 Methodology

The scope of the corporate cross-border mobility concept is considerably greater than hitherto appreciated, providing interesting new avenues for theoretical and methodological development in this area [16]. To focus, Wright [17] pioneered in "beyond BREXIT" research for European capital markets. Corporate cross-border mobility definition by experts [12] is put in conjunction with foreign direct investments.

A number of Hard BREXIT research reports like one by University of Oxford [5] detail the damage that has been wrought on the UK's economy by the BREXIT process. The abovementioned one finds that the auto-industry has already lost 9% of its volume due to BREXIT, and overall investment has dropped by 80% over the last three years. Influential German source Der Spiegel [1] blames BREXIT for industrial decline in the UK. Leklera [9] was the first to investigate how BREXIT would affect Latvia. It was departure from hailing reports [7]. Latvian economist, member of the Fiscal Discipline Council Steinbuka (2019) recently voiced new fears of declining rate of economic growth in Latvia under uncertainty linked to BREXIT. Unfortunately no measurable figures were presented for Latvia.

The FDI trends observed in Latvia are contradictory. On the one hand, international capital flows do exist and come in Latvia. On the other hand, the uncertainty damages FDI flows. Case of UK FDI in Latvia deserves special interest.

In this research, the donor country is called the United Kingdom (UK) to underline its integrity. This also is the name used by the Register of Enterprises of Republic of Latvia.

The effect of BREXIT on corporate mobility is under multiple investigations. Retreat in internationalization and globalization of business on principal grounds [11] is one direction. More practical issues in international corporate administration [8] make another direction. The research by the Author brings new outlook.

Author employes both qualitative and quantitative methods of FDI research. Qualitative methods [13] include literature review, personal observations and experts' interviews. Quantitative methods are represented by time series and structural analysis as well as charts plotting. In the further research, questionnaire [3] would be recommended. However, it proved not possible in the time of this investigation.

The time series for analysis consist of non-financial and financial indicators of the UK FDI in Latvia. Manifestation of time series in linear charts [2] proves a useful instrument for research in this case. It provides for clear picture of what has happened.

Linear trend where relevant is used to disclose characteristics of growth and decline. Both indicators Y and R squared are represented and commented.

One more method of statistics is important for research like this, namely calculation of the Standard deviation, or Sigma. It is employed when the researcher needs to find out if the uncertainty of the process under scrutiny is growing.

At any given time, a dynamical system has a state given by a tuple of real numbers (a vector) that can be represented by a point in an appropriate state space (a geometrical manifold).

The evolution rule of the dynamical system is a function that describes what future states follow from the current state.

Often the function is deterministic, that is, for a given time interval only one future state follows from the current state. However, some systems are stochastic, in that random events also affect the evolution of the state variables.

Methodologically, it is advisable to subdivide the time series into parts, calculate the standard deviations for the parts in their sequence and to compare the results. The Author found it reasonable to subdivide time series in two equal parts and to compare by dividing the most recent result over the prior period one.

The final step in this research is comparison of trajectory of UK FDI with the total FDI in Latvia for the same period. The latter manifests all factors. The discrepancy reflects country specific factor set, mainly BREXIT. It provides for evaluation of loss of FDI due to BREXIT factor. Thus, the first evaluation will be produced and can serve for further corrections.

3 Results

On the basis of annual statistics, Author traced the start of the recent decline of the non-financial indicators of UK FDI in Latvia (see Fig. 1).

One can see that in 2016 the decline manifested itself although it was insignificant. Unfortunately, it was only a start. After the BREXIT referendum, clearly cut tendency of falling numbers of recipient enterprises, investors and deals is disclosed.

For deeper insight, monthly chart for the three years under consideration was plotted (see Fig. 2).

It can be seen, that the number of UK FDI recipient enterprises in Latvia and UK investors sharply declined, with 28 of 36 months being in the red. Their investment deals in Latvia fluctuated on the same level with R^2 a little above zero (wherefore in uncertainty) in 36 months after the BREXIT Referendum.

Monetary Figures demonstrated more decisive reaction on BREXIT referendum (See Fig. 3).

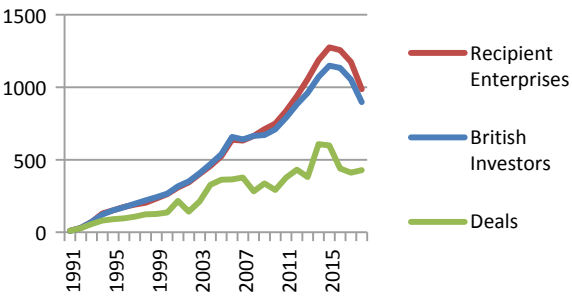

Fig. 1 Number of UK FDI recipient enterprises UK investors and their investment deals in Latvia 1991–2018

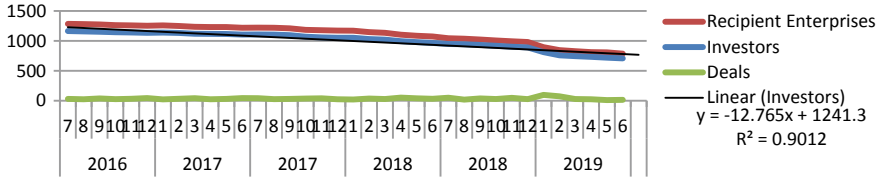

Fig. 2 Number of UK FDI recipient enterprises, UK investors and their investment deals in Latvia, in 36 months after the BREXIT Referendum

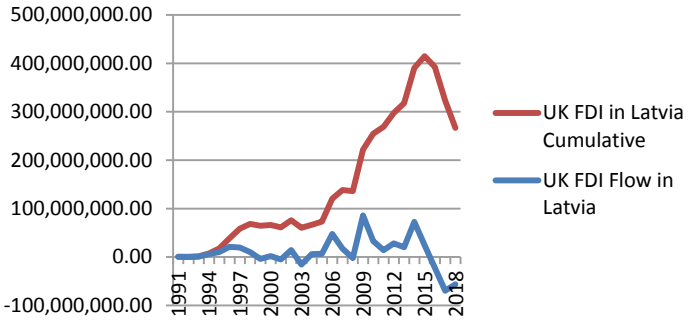

Fig. 3 UK FDI in Latvia cumulative and yearly flows euro 1991–2018

All time high cumulative figure was documented in 2015 only to start falling in 2016. The FDI flow, however, signaled decline in 2015 to rush then in the negative zone in 2016–2018.

More detailed financial data on the 36 months after the BREXIT referendum can be observed in the linear chart plotted (See Fig. 4).

The chart shows evident decline of the cumulative figure because of dramatically low investment flow. The latter showed no signs of potential revival. 28 of

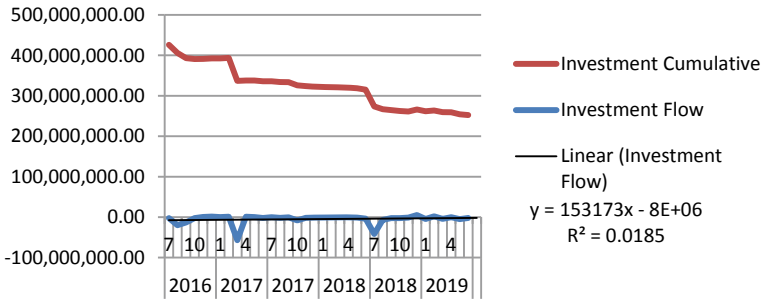

Fig. 4 UK FDI in Latvia cumulative and flow in 36 months after the BREXIT referendum 2016–2019, euro

Table 1 Standard deviations of non-financial and financial indicators of the UK FDI in Latvia in 36 months observation period

	STDEV deals	STDEV investors	STDEV recipients	STDEV flows
First half	719	3,169	3,289	1,350,543,547
Second half	2,100	10,855	12,253	949,971,916
Times	292	343	373	0,703,399,693

36 months [14] brought negative FDI flow. March 2017 and July 2018 were extraordinary in outflow of the UK FDI from Latvia, above 40 million euro each. No inflows of above 6 million euro were registered in the eight good months.

Is the uncertainty in UK FDI flow in Latvia increasing in the time framework? Standard deviations were calculated for the first 16 and the second 16 months as two halves of the time span. The results are presented in the table (see Table 1)

One can see that growing uncertainty measured by the standard deviation manifested itself clearly in non-financial indicators. However, it did not manifest itself so clearly in the financial indicator of FDI flow. Looks like the shock among investors got smoothened by necessity to go on running business in Latvia. For example, 25% of the UK FDI traditionally [10] are in the Real Estate. This contradiction reflects confusion or conflict of motivation of UK investors in Latvia. Everything is unclear with the BREXIT. Questionnaire is recommended for further research of such changes.

Can one attribute to BREXIT only that the total FDI in Latvia is declining? Definitely, there are many factors that affect the FDI flow in Latvia. fDi Markets (2019), the online database tracking cross border greenfield investment covering all sectors and countries worldwide, continuously reports shrimping FDI in the EU. Real-time monitoring of investment projects, capital investment and job creation prove that great troubles challenge the EU.

According to data from UNCTAD [15], official FDI flows declined by 16% in 2017 to an estimated $1520bn, pulled down by a 23% decline in M and A. fDi Intelligence data on greenfield FDI showed a similar decline of 15.2% in capital investment and an accompanying 9.4% decline in global job creation from FDI.

In 2018, the same trends prevailed. Global flows of foreign direct investment fell by 23% in 2017. Cross-border investment in developed and transition economies dropped sharply, while growth was near zero in developing economies. With only a very modest recovery predicted for 2018, this negative trend is a long-term concern.

Cumulative FDI in Latvia started to drop since January 2016 all-time high of 7569 mln euro irrespective of BREXIT. The dynamics of the process is represented in the chart (see Fig. 5).

The linear chart includes 19 of 36 months of negative FDI Flows. Despite some good months, the trend to decline is evident. FDI came to Latvia from 124 countries with minimal BREXIT effect. The total cumulative FDI lost 486.94 mln euro, i.e. dropped by 6.63%. The above figures should, however be investigated further.

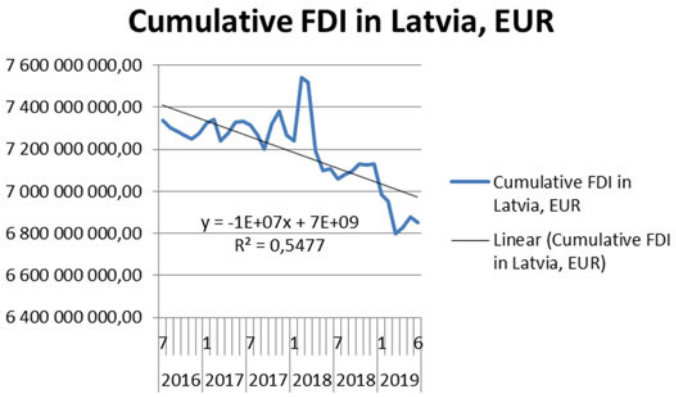

Fig. 5 All FDI cumulative in Latvia in 36 months after the BREXIT referendum 2016–2019, euro

UK cumulative FDI in Latvia dropped by 173.79 mln euro, i.e. by 40.78%. For Latvian size, it is dramatic because it equals 35.69% of the total cumulative FDI loss in the period. One can even suppose disproportional UK cumulative FDI loss.

On the basis of yearly data, calculation includes two steps. First, singling out the BREXIT effect in UK FDI in Latvia by deducing the fall rate of UK FDI by the fall rate of all FDI (35.69–5.79) which gives 2990% points. Second step is calculation of absolute loss of UK FDI in Latvia due to BREXIT by applying this percentage to the cumulative figure of UK FDI before BREXIT (in 2015). The result is the loss of 123 964 069 EUR.

This figure can be introduced in the scientific circulation as the minimal one because a more precise calculation can be done on 36 months statistics basis.

In fact on the basis of monthly data, the UK FDI fall in the post BREXIT referendum time was 40.78%. We cleared it of the 6.63% fall of all FDI in Latvia and applied the result to the July 2016 cumulative volume. In this way the corresponding loss of UK FDI in Latvia was 145,534,972.91 EUR. The figure can be introduced in the scientific circulation as the most precise one.

The investment climate in Latvia is worsening, despite some optimist experts' opinions. Such important challenges and risks underlined by IMF Article IV Mission [6] as continuing emigration and diminishing population, championing in the EU elderly people to working population ratio, scandals concerning bad treating of entrepreneurs by the State revenue service (VID) and misuse of anti-money laundering mechanisms in the banking sector are detrimental for both the business by local and by foreign investors. Geopolitical risks are being intensified. Latvia is sensitive to a part of them. No wonder, UK investors hesitate investing in Latvia.

On 10 April 2019 the UK and the EU agreed a second delay to BREXIT until 31 October. It means extension of the period of hesitations and sharp political struggle. Hence delay in the revival of UK FDI in Latvia.

4 Conclusions/Recommendations

The hypothesis that after the BREXIT referendum, UK FDI in Latvia declined is proven. The UK FDI in Latvia in 36 months after BREXIT referendum declined by 40.78%. The effect of BREXIT singled out by the Author is by 34.15% decline of the UK FDI in Latvia.

The corresponding loss of UK FDI in Latvia was—145,534,972.91EUR. It makes 3569% of the total loss of FDI in Latvia that occurred in the three years' period.

The decline of the UK FDI in Latvia by 173,793,410 Euro cannot be attributed purely to the BREXIT. Worsening of the investment climate in Latvia and intensification of geopolitical risks, both real and anticipated, did and do contribute to the falling UK FDI.

Further research proves necessary. First, the BREXIT effect is not expired, FDI in Latvia time series are to be prolonged and monitored. Second, decline in the standard deviation of the UK FDI flow in the second half of the 36 months' period is to be investigated in depth. Third, differences of regional attitudes to BREXIT in the UK can matter. In the UK, England voted for BREXIT, by 53.4% to 46.6%. Wales also voted for BREXIT, with Leave getting 52.5% of the vote and Remain 47.5%. On the contrary, Scotland and Northern Ireland both backed staying in the EU. Scotland backed Remain by 62% to 38%, while 55.8% in Northern Ireland voted Remain and 44.2% Leave. Can this set of attitudes affect the UK FDI flow in Latvia? It can be a subject of further research with tracing geographic area of origin of the UK investment flows in Latvia. Questionnaire seems the adequate method for further research.

City: Legal and Urbanological Factors of Digitalization

Vladimir V. Tabolin, Anastasiya V. Pitryuk, and Ibad Musa Ogly Abbasov

Abstract The purpose of the article is to identify current interdisciplinary scientific and practical problems in the context of the digital transformation of city administration within the emerging domain of legal science (legal urbanology). Given the complex nature of the object under study, a comprehensive study of city life requires an integrated methodological approach based on a synthesis of the findings of the legal, economic, sociological and political research factors. A significant role in the methodological provision of the study is given to the integrated approach, which allows regarding the city as a dynamically developing open social system with a complex hierarchy and developed social institutions and relationships. The city, being the most important element of the system of resettlement and human life, a key link in the formation of states, in the development of mankind in general, and scientific and technological progress in particular, now, like all other social systems, has entered the period of implementation of the smart city concept. Actual complex problems of legal regulation of the legal relations system in cities, including the social, economic, environmental aspects of their manifestation, described in the theories of various humanities in the framework of legal urbanology, are considered. On the example of the city's environmental problems, a specific complex structure of the phenomenon is shown, requiring study with the involvement of various branches of knowledge. It's concluded that the modernization of modern society and its transition to a new digital paradigm affects all social spheres, but giving the degree of concentration of economic, political, social, informational and other resources in cities, they act as an indicator of the ongoing transformation of the role of cities in the development of the country.

1 Introduction

Being the crucial element of human resettlement and life system, a key link in the development of states, mankind in general, and scientific and technological progress in particular, the city like all other social systems, has started the implementation of the smart city concept. Digitalization and introduction of new information technologies in city administration requires own legal research and underpinning, as one of the conditions for effective legal regulation is the prompt update of laws, and sometimes the advanced scientific justification of the legal system development. Current multi-faceted issues of legal regulation in cities, including their social, economic, environmental factors and solutions in the context of digitalization, have been addressed. A specific complex structure of the phenomenon to be studied with the help of various domains of knowledge has been shown using the example of environmental problems in the city. Urbanology, in its broadest sense, is a comprehensive scientific domain that combines human and natural scientific methods for the study of the legal, economic, social, philosophical, psychological, urbanistic and natural science factors of urbanization and the city as an important civilization object.

Studies of the regularities governing the establishment, development, and role of the city in the life of mankind have been carried out for several centuries [1] and have been continued until now when civilization offers to develop new forms of life on Earth. Almost all human sciences deal with various factors of life and activity in a modern city.

In our opinion, this fact is related to a new, much more complex and critical stage of the development of human civilization, and above all, a new qualitative breakthrough in science and technology, namely the widespread use of digital technologies, artificial intelligence and the introduction of robots in the people's life. Under these conditions, it is of huge importance to provide a comprehensive scientific insight into the city, as a foundation for the socio-economic development of both countries and the whole world. Such scientific domain could be an urbanological theory that combined the basics of all other human and natural sciences about the city. But this cannot be just a summation of the opinions of various scientists, but a new scientific vision of the whole range of problems, both directly related to the life of the city and the residents, and urban civilization in general.

In our opinion, the problems of a comprehensive legal study of the city could be solved by legal urbanology, a new domain in legal science that combine from the legal standpoint knowledge of various branches of the human and natural sciences about the laws governing the emergence, development, and life of urban civilization in

general and the city in particular, branches and institutions of law that govern public relations arising in social, economic, political, urban, housing and utilities and other areas of population' life, about the legal provision and promotion of positive trends in the urbanization, contributing to the sustainable development of the state and society [2]. From these standpoints, legal urbanology can be considered as a means of codification of various theoretical ideas about the city.

2 Methodology

The research background served the long-term scientific research of the authors, based on a systemic analysis of the city as an object of the integrated scientific study of objective reality, which is rather independent integrity investigated by the group of human and natural sciences from different angles. The city as the subject-matter of legal science is the system of social relations arising in the life of their participants and governed by rules of various branches of law that define its legal status, the structure of government and management bodies, their functions and powers, the procedure of social, economic, financial, economic and other types of city activities. When studying the legal foundations of urban management, we have conducted an analysis of law enforcement practice at all levels of state and municipal government. The analysis allowed us to cover topical issues in this field to the full extent and develop recommendations for adjustment of state and municipal administration systems and legal methods for the government of social processes in cities under conditions of modern economic and management digitalization.

The study of the goals and methods of exercise of the legal regulation of urban governance in the modern realities of the post-industrial and digital society requires an integrated methodological approach based on a synthesis of the findings of the legal, economic, sociological and political research factors.

The methodological background of the article was the general scientific analytical method of cognition and corresponding private scientific methods such as technical-legal, system-structural, comparative-law, formal-dogmatic, etc. Their application allowed us to examine the documents selected for the study in terms of relationship and interdependence for the perspective of their integrity, comprehensiveness, and impartiality. The leading role in the analysis of urban processes studied by legal urbanology belongs to an integrated approach, which makes it possible to outline the structure of the social phenomenon under study, investigate particular social and especially legal institutions and their relationships and hierarchies, and reveal the vital factors of dynamic processes displaying the current state of the city as a phenomenon. The digitalization of the economy, public area, and the city administration system at this angle poses a challenge to the city as an open and dynamically developing complex system. In such advanced conditions, urban systems not only transform in the digital revolution but also gain new technical capabilities for the solution of much more complex integrative tasks thereby taking the organization of society to the new level. Therefore, a systemic analysis can simulate the social processes of the city, as

well as extrapolate the studied properties of the models to their original and suggest ways to enhance the legal provision of the city administration.

Significant attention in the study is paid to the technical and legal method, which allows not only to explain the mechanisms of applicable legal regulation but also to assess their efficiency and consistency with the main lines of development of urban law. The combination of urban models and the government structure make up the conceptual theoretical structural-legal model of the city.

3 Discussion and Findings

Famous Russian legal scholar Yu. A. Tikhomirov highlights the key legal problems of modern administration, associated with the that for a long time people got used to understanding of administration as a purely organizational mechanism with built-in programs and action technologies. Inevitably, the worldview factor and various social interests to be secured by administration fell out of law-maker's sight. This impoverished the view of such a complex phenomenon as public administration. It seemed that administration is brought from the outside and from the top, and people and organizations are only left to be drawn in it and self-develop in predetermined conditions [3].

The main question is "Is it a city for people or are the people for a city?" What answer will be given by municipal authorities, that way the city will be governed. But in addition to personal reasons, there is an impersonal situation when residents of megacities lose their identity and turn into labor resources, a consumer society, the Internet community, electronic citizens, bloggers, "classmates", etc. Electronic communications and social networks have become an ostensible form of public participation in the city administration.

There are three main models of electronic participation:

(1) *managerial* (focuses on the efficient provision of government services via e-government system);
(2) *advising* (the population's opinion is accounted for in the decision-making);
(3) *the bilateral interaction of the government and population* [4].

Digitalization and the introduction of new information technologies in the city administration w

Theoretical studies of the city are carried out by scientists from various humanitarian fields. The most famous are sociological, economic, urban, socio-philosophical and socio-psychological and other theories of the city [5, 6].

All spheres of the city's existence are somehow connected by a complex system of urban legal relations into a single integrated dynamic sustainable structure. Thus, we can, through law, study the organic unity of the scientific approaches of various humanitarian theories to the analysis and description of the vital functions of the city and its inhabitants.

This can be done within the framework of legal urbanology, a new direction in legal science, combining, from a position of law, knowledge of various branches of science on the laws governing the emergence, development and functioning of cities, branches and legal institutes that regulate social relations arising in social, economic, political, urban planning, housing and communal and other vital processes of the urban population.

Urban legal relations have a specific character. They have territorial and complex legal nature since they are connected with the exercise of multiple and diverse functions to meet the population's needs and ensure city administration and self-government.

The subjects of urban legal relations include federal and regional government authorities that carry out legislative, executive and judicial activities in cities, as well as municipal authorities that provide daily administration through the adoption of municipal legal acts, the performance of specific business activities in accordance with their functions and objectives.

Along with that, the key subject of these legal relations is the city population, without which the legal and physical existence of the city is meaningless. The basic rights of residents are the fundamental rights and freedoms of man and citizen, enshrined in the Constitution of the Russian Federation and secured with the essential conditions for their exercise and the effective operation of the municipal administration.

However, the population has not only rights but also responsibilities, which increase as the city grows due to ever-complicating mechanisms of its existence. For example, in a megacity like Moscow, a resident always should observe certain legal rules: at home (rules for the operation of the buildings and equipment, liability for noise and damage to private or collective property, payment of utility services, waste disposal, fire safety, etc.), in the city (traffic rules, use of public transport, relationships with other residents, representatives of state and municipal authorities and administrative bodies, etc.), in a shop or entertainment center (civil-law contractual and other rules for the protection of consumer rights), at work (professional duties, occupational health and safety techniques, relationships with colleagues and the employer, etc.). In most situations, the responsibilities prevail [7].

As Tikhomirov notes, the city resident is continuously changing his legal status and passing from one to another. The industry codes and other laws establish occupational and labor status, entrepreneurial status, educational status, medical status, consumer status, taxpayer status, etc. In our opinion, this is the ultimate expression of legal urbanology. Any city resident with various social and legal statuses, engaged in any legal-specific activity is always within some legal relations intertwining all peculiarities of his city life into a single dynamic system which is controversial but fairly stable. In other words, this is the basis of the structural model of a man in a city, which presents in a simplified way how he leads his diverse life, performs legal and non-legal actions in accordance with the law, own visions, needs, and interests.

The socio-philosophical and psychological factors are methodologically important in city development forecasting. Some scientists believe that future studies of the

city should be focused on the provision of the best possible access to public resources and benefits for each resident through the exercise of his "right to the city" [8].

The key factors of the city economy include a high concentration of consumers, advanced development of infrastructure, high competition, increased density of information and innovation environment, etc. An important socio-economic task is also the legal provision and development of urban marketing (branding), the idea of which is to represent the city as a safe and favorable place to live and run a business.

The current trend of economic digitalization is the transformation of mass consumption, which is a typical example of a complex phenomenon of the urban environment because it intertwines economic, legal, psychological, environmental and other factors.

Let's address the systemic problem of legal regulation of environmental and economic issues of urban life. The inconvenient and very inert system of legal regulation of environmental protection does not meet the demands of aggressively developing the environmental consciousness of the population. For example, the demand for environmentally-friendly goods and services is being created. Actually, the whole sector of the economy is yet not provided with a system of state legal regulation.

An alternative solution developed in Western countries [9], environmental certification by public companies, has not yet reached a desired level in the Russian Federation. The major trend of the modern economy is the departure from mass consumption and its customization, which means the orientation of production to the individual consumer and his preferences. It is noteworthy that these preferences are developing in the course of social adaptation under much-weakened positions of centralized ideology and popular culture. Industrial society tended to high standardization of social adaptation, which has been brightly expressed in Soviet times. The transition to a post-industrial society and the development of information technology is accompanied by the establishment of conditions for generation of an individual and very specific range of consumer preferences, which may include demands to the environmental component of the production of goods and services that earlier have been out of their interests.

Customization of consumer preferences is associated with the development of social networks and other digital technologies that allow everyone to select an individual pool of information, cultivate specific tastes and preferences of the customer that don't depend on the social environment, which lay conditions for the development of customer-oriented business models to adjust the output in flexible terms and reduce the industrial load on the environment. Thus, cultivated consumer demand is turning into a key instrument that triggers green production and consumption.

In a modern city with the highest anthropogenic load, which is an obstacle to the environmental safety of the urban environment, the developed environmental culture of the consumer leads to the cultivation of demand for environmentally friendly products. The environmentally safe production in the world is premised on laws, certification, and standardization. The last two terms are contained in Russian environmental law but insufficiently governed by law. It is a certification that underlies the applied marketing mechanism (product labeling) which is applied to meet a public goal of

the environmental safety provision. The development of environmental certification has the role of an important economic mechanism for environmental management.

Another environmental and legal problem of urban areas is a different environmental state in cities where large industrial facilities are located. Environmental management is based on the monitoring of environmental parameters. It has successful implementation but the results cannot always be a trigger for economic promotion mechanisms that can be useful in environmental protection. There is a popular practice to keep environmental certificates of large cities and conservation areas, but it is not extended to individual areas and municipal lands. The application of modern information technologies in the acquisition and analysis of these data would help to know a real dynamic state of matters in urban territories with the account of many critical parameters, which in turn will allow municipal authorities to make prompt and strategic decisions based on more impersonal and independent assessments [10].

Besides, the measures of environmental monitoring can be expanded by calculating average indicators of highways congestion and taking into consideration the vehicle-to-population ratio of adjacent urban areas. A comprehensive environmental certificate meets the principles of exercising the constitutional right to reliable information on the environmental state and will affect the market value of the real estate, and, therefore, will lay the basis for the development of an economic mechanism to promote environmental protection by municipal authorities. It is the development of economic promotion mechanisms that can enhance the performance of urban environmental policies to a great extent.

4 Conclusions

The digitalization of society witnessed by us have an impact on the manifestation of current issues related to sustenance of the city life. The transformation of public institutions requires new legal mechanisms for the governance of urban public relations to be developed. On the other hand, opening up opportunities for the development of new tools and techniques makes it possible to raise the efficiency of the city administration.

Thus, the modernization of present society and its transition to a new digital paradigm covers all social issues, but, given the concentration of economic, political, social, informational and other resources in cities, they act as an indicator of the ongoing transformation. The key feature of the urban economy from an urbanological point of view is its dynamic and interdisciplinary approaches to organization and regulation since the urban economy plays a decisive role in the population's life, physical existence and image of the city. Forward-looking projects in this area are the various concepts of the "smart city", which imply the high performance of urban infrastructure and refinement of urban resources management.

Social and Political Factors of Smart City Administration in the Context of Digitalization

Aleksandr A. Turovskiy, Aleksandr D. Aseev, and Nikolay E. Sokolov

Abstract In modern conditions, digital technologies are increasingly penetrating the city administration system, and cities of a new technological form (smart cities) are emerging. The article gives a holistic and reasoned understanding of the social and political factors of the smart city administration, as well as substantiates challenges related to the digitalization of the urban environment. Also, the authors discover positive foreign experiences and address the domestic practice of the introduction of particular elements of the "smart city" model. In addition, issues of social and political nature arising in designing and developing the concept of "smart city are investigated. With the help of the methodological approach, the authors present the terminological and conceptual framework, show a wide range of opinions about the "smart city" concept and reveal its nature and meaning. The purpose of the study is to justify the trends towards the establishment and development of a "smart city" within the discourse on "smart city" taking into account social, cultural and political factors, possible risks and their implications. The study has found that the "smart city" as a complex socio-technical system is an interaction between the infrastructure elements of society, its subject-matter realities and human behavior within the controlled human-machine relationship and consistent social conditions. The article represents the main advantages and constraints of the Smart City project implementation. It is emphasized that this process brings not only qualitatively new conditions, transformation, renewal of the city, but also places new requirements for the safe life of the population. The statement that the evolution of a smart city starts when the ICT foundation contributes to the development of democracy in agglomerations is proved.

1 Introduction

The entry of human society into a new economic era, associated with the development of modern advanced technologies and digitalization requires a new level of the city administration. The city undergoes diverse processes and biggest-ever changes in terms of nature and dynamism bringing destructive social and environmental consequences. The modern city is a super-sophisticated multi-tier system that consists of multiple elements and factors interacting with each other and the external environment and absorbs technical, technological and other innovations. All these facts make necessary continuous transformation of the management model and its adaptation to changing external environment.

The speeding up urbanization and the widespread use of ICTs provide the conditions for the elaboration and development of the "Smart City" concept (the smart city of the future) as an attempt to unlock urban technological evolution. The concept is intercommunication of people, computer systems and innovative technologies seeking reasonable management solutions to mitigate environmental deterioration and other negative effects of urbanization. This is an urban space with the technological, human, social and cultural capital of the community aimed at the generation of new knowledge on the settlement of urban problems and enhancement of resistance and interconnected physical infrastructures. Cities become smart if full-fledged communication between the software system, server and network infrastructure, and client devices is reached.

Modern urban technologies help to make reasonable management and political decisions, effect communication between the city administration and society and choose methods to raise the populations' quality of life, where a key role is played by ICT. The establishment and development of a smart city imply innovative transformations of all government levels and areas of city life. The smartness of a city means its ability to competently integrate all its resources, effectively achieve the goals set in the city's development strategy [1–3].

Depending on the performance of ICT, innovation and local priorities, a smart city has a different manifestation and a unique form. This is explained by a complex adaptive system with components related to both the physical and social areas. The physical components include the physical resources of the city and their processing and distribution. Social components are understood as intangible elements (people, social institutions, social activity) within the city. All types of tangible assets (buildings, networks, bridges, etc.) are called "hard" components and intangible resources (organizations, knowledge, wealth, etc.)—soft components. Based on these definitions, the city is considered a platform for the coordination of all the elements.

2 Methodology

One of the key theoretical issues of smart city topic is the terminological and the conceptual framework. The term "smart city" as well as the term "digital economy" is one of the most widely used in the scientific literature over the past decade. This term has replaced the concept of the digital city. The first evidence of a smart city appeared in 1997. At that time, there were more than 2000 virtual cities and urban web pages, as well as the term "virtual city" based on the World Wide Web (WWW) and acted as an electronic alternative to real urban districts was used. The early prototypes of smart cities were the projects of multifunctional polises near Adelaide (Australia) and Cyberjaya and Putrajaya (Malaysia). The "smart city" has a wide range of meanings and represents a rather complex, dynamic and ambiguously interpreted term.

The scientific sources contain various opinions on its essence. The are many definitions directly related to an attempt to reveal its complex framework. The essence of this concept is presented in such a way that it gives the impression of a variety of approaches that are not interrelated and interpreted in a rather broad sense. An analysis of the theoretical developments of the leading authors on this issue indicates a wide range of judgments among foreign and domestic researchers and each author holds his own view on the content and course of smart city development. According to most researchers, the concept of "smart city" due to its complex nature cannot have one simple definition and need several ones.

Among all judgments on this issue, we should highlight the standpoint of the group led by Rudolf Giffinger [4]. In its opinion, a city can be deemed smart, if long-term planning is succeeded in terms of six parameters. These are "smart economy", "smart mobility", "smart people", "smart approach to the environment", "smart lifestyle" and "smart government", which are based on a "smart" combination of capital and concerned residents who take independent decisions. From the standpoint of Boyd Cohen, "Smart city" is one that uses ICTs to be smart and efficient in using resources, energy, improving the quality of public services, mitigating the negative impact on the environment and developing a green economy [5].

From the perspective of a group of domestic authors, "a smart city should be regarded as a single system related to urban management and based on energy-saving and energy-efficient technologies and impartial information. (Medvedeva et al.) The approach interpreting a "smart city" as one contributing to the sustainable development of society, providing economic growth, social integration and environmental balance deserves particular attention. The extensive definition of this term is reflected in the UN program on the promotion of sustainable development of settlements. In addition to the above opinions, there is a wide range of other judgments related to this phenomenon. With the growth of companies offering technological solutions for smart cities, as well as "smart" initiatives, this term has become so ambiguous that it has propelled researchers to focus on the establishment of its frames [6].

In modern academic literature, two main methodological approaches used by researchers in the conceptual developments of "smart city" are particularly distinguished. Under the first approach, a "smart city" is one where technologies play

a decisive role. According to the second approach, a smart city is defined as an outcome of a balanced combination of technological, social, economic and environmental factors, comprising features of digital measurements, connected systems and flexible computing infrastructures that respond to the emergence of new online technology interfaces.

3 Findings

The city is a super-sophisticated multi-tier system with a variety of actors continuously communicating with each other and the external environment and absorbing technical- technological, organizational and other innovations. Under these conditions, a qualitatively new level of administration has become highly important. In addition to technical and technological factors, it allows taking into account socio-political ones, reaching an agreement between actors and working out an effective urban strategy aimed at the solution of city problems and promotion of development. Smart development within the smart city concept is an innovative project where the city is considered as an experimental area.

The consistent establishment and development of "smart cities" started the first decade of the 21st century. The impetus served an idea of IBM how to use the smart technologies of the city to ensure sustainable development and raise economic efficiency only with the help of a technological approach. Besides, it is suggested that a "smart" infrastructure can solve many urban problems, as well as improve the quality of life. During this period, the first real smart cities have been erected "from scratch" in Sangdo (Korea), Iskander (Malaysia), Masdar (Abu Dhabi, UAE), which became the experimental areas of large IT companies. This was an attempt to put into practice high-tech cities where the technologies would be developed in terms of particular elements not interconnected. Along with that, social, ethical respects and democracy in high-tech cities of the digital age were not taken into account, and technological systems did not possess human-centric qualities and adaptative abilities to people. This position has been criticized by celebrated foreign scientists (Townsend et al.), who did not agree with the corporate vision of smart cities. Researchers justified their stand by the fact that the technocentric approach to the design and delivery of "smart city" concepts disregards the socio-cultural and political factors of human civilization and can jeopardize the existence of human society [7].

The second stage of the development of smart cities is administration based on the use of technologies as tools and a strategic vision of city evolvement. At the same time, initiatives of residents and governments are integrated, relationships between the authorities and society are forged, information from all areas of the city's life is brought together, and "smart administration" is introduced. The city refines administrative processes through the entrenchment of integrated systems. At the same time, intelligent systems are implemented not only in the administrative area but also in

energy, mobility, etc. The technological approaches are worked out based on democratic principles, this contributes to the upgrade of the socio-technological approach, under which technology is a tool to achieve strategic goals.

Within the third stage, the concept of "smart city" is changed in some way and supplemented by new administration forms. Besides, the rights and opportunities of residents are broadened using ICT. This pioneering idea dramatically changes the nature of communication in urban space. The most successful examples of "smart city" implementation are Vienna, Vancouver, Barcelona, Amsterdam, etc., using a policy of openness and transparency at all levels of urban administration based on a "smart" combination of capital and conscious residents making independent decisions. Not only senior officials who set urban policy but also representatives of the urban community are getting involved in the establishment and development of smart cities at different stages of managerial and political decision-making. Moreover, access to data is open, which contributes to the development of innovative solutions.

This is proven by a vivid example of Barcelona which instituted a "smart urban ecosystem" of sound administration, demonstrating the transparency of all processes, the joint participation of all categories of people, providing conditions for commercial partners and creating social and economic values securing the digital rights to the city. Within the strategic direction of the city's development, the system created a sense of trust between the public and private sectors and ensured the co-governance of urban processes. Using city data, the government has turned the Spanish province in one of the most successful cities in the world both from a perspective of business and social suitability of the city, having laid conditions for mutual assistance of all parties involved and provided transparency and democracy. Engraining a sense of digital right to a city in civil consciousness improves their relations with a smart city.

Interest in the idea of "smart city" is exhibited in Russia and constantly discussed, besides one tries to put into life some systems of the "smart city" concept. Pilot projects "smart city" are being implemented in Moscow, Kazan, St. Petersburg, Samara, etc., where there hasn't been a comprehensive understanding of this concept. The transition to smart technologies is constrained by insufficient business support by the federal and regional authorities, high depreciation of funds, as well as weak civic engagement in this process. The authorities, scientific community and practitioners have not yet developed a unified approach to answer the questions "What for we need a smart city?", "What are the development prospects?" and "What it should be in the future?". Local authorities do not know how to change innovative business models that can convert current funding models into the desired result. Besides, city leaders have a deficit of the skilled staff to take advantage of these technologies. Without appropriate changes in the administration system and well-trained staff, the results of smart city initiatives will mismatch their potential [8].

All-permeating and all-encompassing administration of smart city using ICT have led to low civic engagement and reinforcement of the vertical power structure. Using smart urban projects, authorities gain access to new tools, but at the same time retain the traditional structure and old management models. A particular problem is a troublesome adaptation of innovative developments (technological, managerial, organizational and socio-political) aimed at resolution of urban issues and the provision of

progressive development. Despite the undeniable advantage of "smart" technologies and their capabilities aimed at the reasonable use of resources, sustainable development, and improvement of the quality of life, they are not prioritized by municipal authorities. This points out that nowadays the authorities and civil society are not yet ready for the widespread entrenchment of innovative models of city development. But authorities do not rule out this possibility in the future, as evidenced by the results of a survey conducted within the Basic Research Program of National Research University "Higher School of Economics" [9].

The authorities are concerned that these technologies are not approved to a full extent under certain conditions. These concerns are allayed by testing "smart" urban technologies.

We are talking about intelligent systems related to traffic, electric power networks, energy-saving technologies and wireless communications of a new generation, which are studied using simulation with special computer programs. Besides, it is tested to what extent technological innovations are compatible with the available public utility and other infrastructure.

The authorities of most Russian cities think about the application of a "smart city" concept mainly in medium or long-term, which points at the infancy of the process. Their ideas of the "smart city" concept are limited by a narrow technological view of the current state of a city administration with a focus on the modernization of the public utilities sector and enhancement of energy efficiency [10]. In the opinion of the famous scientist Boyd Cohen, all the concepts of a "smart city" contain risks, which he classified into three groups, such as investment, recycling, and assurance of human security [5].

As for human security, HP Fortify studied widespread home smart gadgets and concluded that they do not grant full safety, explaining it by that "smart" things bear the main risk. In the world, there are a lot of digital faults and their number is increasing every year. Besides, the development and implementation of new technologies are always associated with a risk of information leaks. This circumstance propels the IT industry to develop more sophisticated applications, and hackers find ingenious ways to get access to them and execute fraudulent schemes. Companies developing many "smart" devices with access to the Internet do not aware of the hazard in the information field. However, we know the vulnerability of hundreds of devices of different manufacturers, which causes an increased risk to the entire city. This is explained by that overwhelming part of the information generated in cities belongs to commercial organizations such as IT companies and mobile network providers, which is a sign that smart cities can turn into "Internet vulnerabilities" over time. In real practice, a willingness to make the city prosperous and well-managed hides some problems. This is the introduction of innovative business models and the development of a strategy adjusted to actual and potential resources due to the lack of detailed procedures on the specific features of a particular territory.

The corporate vision of smart cities was a reason for criticism on the part of E. Townsend, A. Greenfield, and S. Marvin, who believed that the modern implementation of the smart city concept is characterized by non-transparency, elitism, corporate lobbying, avoidance of ordinary people, and the triumph of neoliberalism. In 2013,

Adam Greenfield (USA) expressed his negative attitude to "smart cities" in his book "Against Smart Cities" [4]. Some scholars (J. Shaw and M. Graham) call for counteraction to the harmful impact of monopolistic companies and suggest founding a civil society movement to solve the socio-political problems on the establishment and development of a smart city.

4 Conclusions

In modern conditions, value orientations, the role of technology in human life, the ways to develop the "smart city" model, which is fixed in the city's development strategy as one of the principal goals, featured as an innovative project and an experimental area, have been rethought. When putting the concept of "smart city" into life, the developers use an ICT-based approach, which includes a block of strategically important social, organizational and political tasks with a focus on interdisciplinary cooperation, identification of unlocked opportunities, elaboration of coordinated development strategies, which helps to avoid failures and reduce implementation costs.

Manufacturers of products, technologies, service providers and funding companies take a keen interest in the initiatives of those cities which administrative bodies can provide the most favorable conditions for such projects. An especially important role here is assigned to the federal government interested in smart city technologies, which makes contacts with municipal authorities, business and scientific communities for joint assessment of the potential benefits from the delivery of smart solutions. Shaping a political course within a smart city implies the right of every resident of a smart city to use ICTs and get access to urban data bespeaks the democratic rights of society to information and its key role in the development of fair and equal urban agglomerations united by digital technologies.

In modern conditions, the powers for urban management are distributed not only between traditional bodies of municipal power but also between the new information monopolists like Google, Alphabet Inc, etc. Control of technological giants over cities and data manipulation has negative consequences for city residents. Exploiting the image of a smart city and its capabilities allows companies to establish and a data market, taking a benefit from the interaction of people with their user-friendly new-media devices.

Management of smart cities as integrated systems presupposes a technological and cognitive approach. Under a technological approach, the decision to be made is associated with the choice of high-tech infrastructure technologies that do not fully satisfy the population's needs and do not contribute to a higher quality of life. The cognitive approach takes into account social factors and human capital using an integrated approach and visual representation that displays relevant information and non-linear interaction of various systems. These tools are based on digital technologies that allow collecting and processing corresponding information, as well

as providing effective expert communication and facilitating knowledge management. Due to the focus on technological and social respects, a wide range of *ethical problems* related to the inevitable collection and utilization of data by governments and companies implementing these technologies fall out of sight. As smart cities are developing, the issue of the confidential data of city residents, their privacy and security are getting more acute. As far as the overall number of people lives in digital or digitally-mediated urban spaces, representatives of society should know how the government instruments the code, implements content, control, and urbanization of this information.

Shift of Paradigms of Personal Income Tax in Russia: From Fiscal to Social

Galina B. Ternopolskaya and Nikolay N. Tyutyuryukov

Abstract The purpose of this paper is to assess, based on legal and economic data, which paradigm prevails in personal income taxation in Russia—a fiscal one or a social one, and suggest the measures to tackle the deficiencies discovered during the analysis. The authors analyze the features of PIT regulations that may improve the people's effective demand and therefore their welfare, and continue with the analysis of tax-related statistics to determine effective PIT rates and potential people's tax savings should the paradigm shift happen. They show that Russian Tax Code virtually neglects the redistribution function of PIT, and after lost of connection between PIT deductions and minimal monthly salary level (proxy to minimum subsistence level, as it was in Law on PIT of 1991) the people with lower revenues, especially the families with children, lose the material sums. This happens along with the decrease in disposable household income, thus hindering effective demand of these people. The authors conclude that fiscal paradigm still dominates in Russian PIT in Russia and suggest the advantages of a shift towards the social paradigm.

income, the main source of personal welfare in current society [9], a redistribution function may be called its peculiarity. The state may use PIT to shift the burden of public spending towards people with higher revenues and alleviate that burden for people with lower revenues or lower level of social security [5].

In this article the authors review the implementation of fiscal and redistribution functions of PIT, assessing, which paradigm prevails in personal income taxation in Russia—a fiscal one or a social one.

2 Methodology

In their research, the authors undertake two approaches. First one includes an analysis of relevant Russian tax regulations, revising those features of PIT, which may reduce inequality of income (especially lighten tax burden on poor people, which is a crucial issue in Russia). Second approach is the analysis of relevant empirical statistics provided by Russian Federal Tax Service (FTS) and Russian Federal State Statistics Service (Rosstat) on the amounts withheld from or retained at the hands of people, number of taxpayers etc., assessing scope of benefits of social nature.

3.1 Analysis of Legal Developments in Russian PIT

The Law of Russian Federation No. 1998-1 "On income tax from individuals" became effective on 1 January 1992. It defined the taxpayers and taxable items, as well as introduced structure of the tax: tax base, tax rates and tax compliance procedures. This law underwent 18 editions, often with retroactive force, which was common in 1990s. Table 1 provides the nominal PIT rates since 1992.

In 1993, the tax rate for topmost revenues went down by 10 percentage points, while the rate for lowest revenues remained the same. In 1996 the highest rate was increased by 5 percentage points, and went up by further 10 percentage points during economic crisis of 1999; the lowest rate did not change. At that period, the foreign

Source developed by the authors based on respective versions of Law of Russian Federation dated 7 December 1991 No. 1998-1 (1992–2000) and Tax Code of the Russian Federation (from 2001 onwards; accessed via Legal information system ConsultantPlus)

tax systems generally features reduction of the tax burden on people with lowest revenues [12].

Chapter 23 "Personal income tax" of the Tax Code of the Russian Federation (TC RF) became enacted on 1 January 2001; it introduced a general flat rate of 13% and have maintained it since. Thus maximum tax rate went down by 17 percentage points, while the tax rate for lowest tax bracket increased by 1 percentage point. The policymakers claimed that such changes were necessary to increase tax revenues to the budget, to legalize personal revenues and to simplify tax administration [4]. The tax authorities actually reported significant increase in PIT receipts for 2001 and attributed it to the improvement of tax compliance due to flat tax rate. However, in April 2017 the economist A. Krutov during interview to OTR TV channel claimed that "the increase in [tax] collection efficiency is a myth. Back then, in early 2000s, the volume of PIT receipts went up due to the fact, that at the same moment it was introduced for military personnel on their money allowance, and afterwards its collection was correlated with tempo of general remuneration increase in the country's economy. There wasn't any increase in collection efficiency". Other researchers made similar findings [3].

Therefore, the beneficiaries of 2001 changes in legislation were the people with middle and high income. As Gazeta. Ru noted, "the introduction of flat 13% [PIT] rate in 2001 meant the increase of tax burden for 98.7% of Russians by 1 percentage point, as lowest tax rate before was 12%. Effectively, the poor at that moment paid for the rich" [7].

3.2 Analysis of Fiscal Statistics

Every tax fulfills the fiscal function—i.e. replenishes the public budget; PIT accounts for 35% to 38% of revenues of consolidated budgets of Russian regions [6], thus being the significant instrument of economic policy. As rating agency "Expert" reports, in 2018 70 Russian regions reported surplus in their budgets, and share of PIT in it was material (RUB 402 billion of additional revenues).[1]

Table 2 suggests that during 2008–2018 average salary increased 1.6 times, while PIT revenues did so 1.2-fold; however, from 2012 (when standard PIT deduction for taxpayers was abolished) the increase rate became similar (64% and 62%, respectively). While PIT revenues in 2012 changed only marginally, the number of informally employed went up and has remained since higher than until 2011. That could be partially attributed to increase of tax burden on people with lower income.

Calculation of PIT incidence includes tax deductions. However, these deductions are not adjusted for annual inflation rate, and their change is much slower than the inflation—which results in strengthening of the fiscal function.

Source developed by the authors based on Rosstat data and Federal Tax Service data (https://analytic.nalog.ru/portal/index.ru-RU.htm)

The authors estimated the "surcharge" of such non-adjustment for 2001–2010. By 2010 those receiving average nominal salary could enjoy standard tax deduction for one month per year. The budget system collected at least RUB 4.6 billion of additional revenue per annum only due to lack of inflation adjustment of the deductions, which meant higher tax burden on all individual taxpayers. The people with lowest level of income suffered most because of violation of "vertical fairness" concept, and this hindered even simple reproduction of the workforce [15].

Since the times of J. M. Keynes the policymakers have been recognizing that the taxes don't just fill the budget—they may be used as an instrument of economy regulation. One of their tasks became the redistribution of the people's revenues, so that those with lower income retained relatively higher share of their income.

Both Russian and foreign researchers discuss redistribution function of the taxes. Generally speaking, the taxes execute it by shifting part of tax burden from the poor economic actors towards richer economic actors [1]. Glukhov and Glukhov [2] note, that "by executing their fiscal function, the taxes actually do not fulfill their social function, which is virtually replaced by the redistribution function, which partially redistribute the accumulated obligatory contributions from all taxpayers via tax policy implementation".

Perekal'skii [8] considered the priority areas of improvement of PIT instruments affecting local budget revenues and people's income. He suggested introduction of general standard deduction equal to RUB 5,600 (about the amount of monthly subsistence level at the time) instead of RUB 400 as per TC RF, and of progressive tax rate. He also showed that family taxation would be appropriate.

Volokhov [16] noted that the salary becomes the general source of people's income in Russia (about 70% of total income). However, his analysis also shows huge share of shadow income (up to 30% of total income). This means direct losses in PIT potential. S. Volokhov concludes on explicit fiscal nature of PIT: since the amount of tax deductions is fixed irrespectively of social and economic position of a taxpayer, PIT does not contribute to social support of poor people or families with children.

Shlyankevich [11] quotes Art.1 of ILO Convention 117: "All policies shall be primarily directed to the well-being and development of the population and to the promotion of its desire for social progress". Following this logic, the flat PIT rate introduced in 2001 does not meet the criterion of social fairness, does not facilitate social and economic reform aimed at promotion of people's welfare and contradicts the Constitution of Russia. The author also suggested introduction of family taxation in Russia, exemption of income up to subsistence level and adoption of progressive tax rate.

Peter et al. [10] reviewed the personal tax reforms in 189 countries. They showed that the countries usually reduce maximum nominal tax rate (weighted average maximum rate dropped from 62 to 36.4% over 25 years covered by research). The authors also determined the statistically significant positive correlation between tax rates and PIT revenues, but this correlation is weaker in case of less developed economies. They further noticed the general simplification of PIT systems, which did not unequivocally lead to lower fairness of tax burden distribution.

TC RF divides the income of individuals into specific groups, each being subject to a particular nominal PIT rate:

- 13%—general rate, applicable to most kinds of income of residents and certain kinds of income of non-residents;
- 30%—general rate for non-residents;
- 35%—fringe benefits, winnings and certain other kinds of income;
- 15%—dividends received by non-resident individuals from Russian companies;
- further rates.

Table 3 summarizes the distribution of respective tax revenues, corresponding tax bases and further statistics, while Table 4 proceeds with comparison of nominal and effective tax rates for particular types of income. This way the skew in tax burden distribution become visible. Effective PIT rate for non-residents decreases through

Table 3 Revenues of individuals taxed at various rates and number of taxable events in 2017

Nominal rates applicable to respective income	Total taxable revenues, RUB billion	Number of tax reports, thousand units	Average revenue per one report, RUB thousand	Withheld amount of PIT, RUB billion	Effective rate, %
13%	29,654.7	93,174.1	316.4	3,302.4	11.1
30%	42.5	154.8	274.8	7.9	18.7
35%	9.8	826.0	11.9	2.8	28.4
15%	31.7	22.8	1,394.6	4.7	14.9
Rates as per double taxation avoidance treaties	72.0	184.3	390.6	8.7	12.1

Note Effective tax rate equals PIT revenue divided by total amount of income taxed at particular nominal rate

the years from 0.86 to 0.62 of nominal tax rate, despite the fact that TC RF does not provide for any tax deductions for this category of income. At the same time the effective general rate rises from 0.75 to 0.85 of nominal general PIT rate—and that for the category covering 99% of personal incomes in Russia.

Absence of minimum exempt income means that even those receiving income equal or less that minimum subsistence level are still subject to tax.

We can conclude that the Russian state retains fiscal paradigm of PIT, while there is no particular consideration of shift towards the social paradigm (i.e. engagement of redistribution function).

3.3 Assessment and Analysis of Budget Revenue from Non-adjustment of Standard PIT Deduction

Table 5 shows that over 2001–2018 average salary increased 13.5-fold, while monthly subsistence level became 6.5 times higher and legal minimum monthly salary became 37.2 times higher. However, the general standard PIT deduction had been unchanged for 11 years (and abolished afterwards). Moreover, in 2001 a person receiving average salary could use it for 6 months, but in 2011 it could have been applied only for one month. By any reason, while the country claimed to be a "social state", this deduction should have been increased, or at least adjusted according to inflation, but the policymakers decided to abolish it.

The authors reviewed the efficiency of redistribution function of PIT under condition of general standard PIT deduction as effective in 2000 (last version of Law 1998-1).

Table 6 shows the amount of annual savings of individuals, should they claim general standard PIT deduction as per TC RF and as one minimum monthly salary for every month of the respective year (since Law 1998-1 effectively provided for such amount of deduction). Since 2012, this amount goes to consolidated regional budgets instead of the family budgets of the taxpayers. And while the majority of Russians has quite low level of income (and quality of life), this situation contradicts the Constitution of Russia, namely Art.3(3) of (the tax, hindering the execution of constitutional rights of the people, is inadmissible) and Art.6 (policy of the state is aimed at creation of conditions ensuring decent life and free development of a human).

Calculations in Table 6 show that if general standard PIT deduction equals to legal minimum salary (which was gradually adjusted to minimum subsistence level), the tax savings of an average taxpayer would increase 37-fold since 2001!

Therefore consolidated regional budgets receive additional PIT amounts, which under social paradigm could have gone to the citizens to improve their personal welfare. The reintroduction of general standard PIT deduction equal to legal minimum salary could retain in the pockets of the citizens over RUB 870 billion, which will positively affect development of human potential and effective demand.

Table 5 Dynamics of average monthly salary, minimum monthly salary, monthly subsistence level and general standard PIT deduction for 2001–2018

Year	Average nominal accrued monthly salary, RUB	Legal minimum monthly salary at year end, RUB	General monthly subsistence level, RUB	General standard monthly PIT deduction (Art.218(1)(3) TC RF, RUB (and upper annual income threshold to apply it, RUB)
2001	3,240	300	1,574	400 (20,000)
2002	4,360	450	1,893	400 (20,000)

4 Conclusions and Recommendations

The disputes on appropriateness of progressive PIT rate run on since 2001. However, Rosstat reports that until 2015 the share of expenses on food in household expenses has been rising—so reintroduction of progressive PIT rate until 2015 would have worsen people's welfare.

From 2016 this share shrinks for people from 6th to 10th decile groups by income—or about 35% of economically active people, which is significant number of people who could pay higher PIT. This means that currently progressive PIT rate might be introduced without worsening people's welfare. It is also possible to reduce tax burden for 1st to 5th decile groups by income without losses in regional budgets.

Table 6 Assessment of annual tax savings of individuals due to general standard PIT deduction

Year	Average nominal accrued monthly salary, RUB	General standard PIT deduction, RUB	Standard deduction applicable, months	Annual personal savings using general standard PIT deduction, RUB	Legal minimum monthly salary at year end, RUB	*Annual personal savings using standard deduction equal to legal minimum salary, RUB*
2001	3,240	400	6	312	300	*468.0*

2010	20,952	400	1	52	4,330	*6,754.8*
2011	23,369	400	1	52	4,611	*7,193.2*
2012	26,629	Abolished			4,611	*7,193.2*
2013	29,792	Abolished			5,205	*8,119.8*
2014	32,495	Abolished			5,554	*8,664.2*
2015	34,030	Abolished			5,965	*9,305.4*
2016	36,709	Abolished			7,500	*11,700.0*
2017	39,167	Abolished			7,800	*12,168.0*
2018	43,724	Abolished			11,163	*17,414.3*

The authors would also like to cite Art.3(1) TC RF: "Every person must pay legally established taxes and duties. The legislation on taxes and duties is based on the acknowledgment of total an equal nature of taxation. At the introduction of the taxes the actual ability of taxpayer to pay a tax should be considered". This provision reiterates the maxim of tax fairness formulated by Smith [13]: the taxpayers "ought to contribute towards the support of the government[2] in proportion to their respective abilities (that is, in proportion to the revenue which they respectively enjoy under the protection of the state)".

Over the time the academicians split the concept of tax fairness into "horizontal fairness" (it two subjects are in the same condition, the tax legislation should apply

[2]Nowadays we would call it "public welfare", as government is but one state body with particular functions.

equally to both) and "vertical fairness" (a taxpayer with better material abilities should be taxed more so that the government could redistribute the tax revenues without harming human development).

The analysis of Russian legislation and statistics shows that the redistribution function of PIT is out of use in Russia and methodology of tax base calculation remains within the fiscal paradigm. The majority of individuals receive revenues only 30% more than minimum subsistence level (which, by the way, does not allow even healthy survival). Due to lack of exempt minimum income and nominal amounts of standard PIT deductions the redistribution function works in favor of wealthier people, and tax burden shifts towards the poorer. First step towards the shift to the social paradigm and improving the people's financial position could be introduction of standard deduction equal to minimum monthly salary for all taxpayers, whose income is subject to tax at a general rate (and the same deduction for children under age is highly desirable). The annual adjustment for inflation should also take place.

The authors would like to mention, that the dominance of fiscal paradigm in taxation of personal income hinders both development of human potential and consumption: the effective demand for goods and services becomes lower, and many suppliers have trouble with selling their products.

Public and Legal Aspects of Digital Governance Transformation in Russia

Vladimir B. Zotov, Aleksandar Djordjević, and Marina A. Cherkasova

Abstract The paper deals with modern trends in digital transformation of Russian system of state administration in organizational and legal aspects using the methods of evolutionary and problematic analysis. Tracing the phenomenon of digital transformation in the broad scientific sense, the author identifies the main gaps in the reformation of public administration institutions under the adopted national concept of "digital government". The author comes to the conclusion that in Russian conditions it is still a question of the initial stage of digitalization of the public sector (service management), compared to foreign countries, and its transition into advanced development in program and conceptual federal documents is excessively hasty, as it requires a systematic restructuring of the public administration system, including in terms of historically established culture and mentality of perception of innovation.

subjects and the organizational basis of their activities, creating new opportunities for consumer satisfaction, forming qualitative changes in the processes being implemented. Terminologically, these changes with the use of digital technologies as a key trend characteristic for various industries and sectors of the economy and social sphere, in the broad sense, are called "digital transformation", which in theory and methodology has not yet acquired a clear interpretation in modern science.

The scientific rationale of approaches to the digital transformation of public governance is based on changing the fundamental understanding of the essence of the state. It should be mentioned that these concepts were widely used in the development of public governance reforms in our country and caused active theoretical discussion in the scientific community (I. N. Baranov, A. G. Barabashev, D. G. Krasilnikov, G. L. Kupryashin, A. V. Obolonsky. O. V. Sivintseva, V. L. Tambovtsev, E. A. Troitskaya and others). In this study, we adopt a broad understanding of the phenomenon of digital transformation and rely on key provisions of the works of these authors in order to interpret current practices and legal regulation of digitalization strategy.

Digital transformation in the public governance system not only changes the requirements to the competence of modern civil servants and approaches to working with data, but also generally creates the prerequisites for the implementation of the model of the state as a digital platform, which is a unique experience in world practice for each country, which suggests significant, qualitatively increasing changes within the framework of this model: while at the first stage, digital technologies serve as a tool for implementing public administration reforms, optimizing and automating administrative procedures, at the next stage, they create variable opportunities for the implementation of services, creating benefits adapted to the personal needs of the population, while embedding these processes in public policy [1].

2 Methodology

The methodological basis of the study was formed by general scientific methods, among which the following should be emphasized: analysis, synthesis, comparison, induction, deduction, grouping, generalization, analogy. Structural and functional, as well as systemic methods were also used.

Modelling and forecasting were used to justify the proposed provisions.

Theoretical basis of the work consisted of fundamental provisions in scientific works of leading Russian and foreign economists and specialists in other scientific fields.

For Russian practice, the intensification of digital transformation processes is of particular relevance today. It should be noted that our country has not yet become one of the leaders in the development of the digital economy: its share by 2025 is planned at 5% of the country's GDP, but these predicted figures are half the current results achieved by the leading countries in this sector. At this, the encouraging fact is that the volume of the digital economy in the Russian Federation in 2015–2019

showed a steady positive dynamics (over this period it accounted for more than 25% of the total GDP growth) [2].

The practical start to the processes of digital transformation of public administration in Russia was laid in 2008 with the approval and start of implementation of the state program "Information Society (2011–2020)" [3]. In the course of its preparation the world experience of formation of similar programs was taken into account, as the Russian practice of digital transformation of state governance by that time showed already considerable lag behind similar processes in foreign countries. The program provided for fundamental measures to implement the concept of "e-government" [3]. In development of the results planned within the framework of the above program documents, Presidential Decree No. 204 of May 7, 2018 "On National Goals and Strategic Development Tasks of the Russian Federation for the Period until 2024". Reference [4] the Government of the Russian Federation was assigned the tasks to implement the national program "Digital Economy of the Russian Federation". Reference [5] and the Federal Project "Digital Governance", within the framework of which, at present in our country, measures are being implemented to introduce digital technologies and electronic platform solutions to transform the functions of state and municipal administration on the basis of an integrated, omnichannel approach to dealing with the life situations of applicants through super-services and tools (mobile devices, social networks, web portals, applications, e-mail); development of institutional forms, minimizing the participation of officials in decision-making on the provision of services and their transfer to the online mode.

However, the main problem for the modern Russian society and public governance system today is the fact that the successful implementation of the set tasks requires consensus in defining the strategic goals of this transformation model, based on a change of views on the phenomenon of the state, as well as a radical restructuring of mentality, improving the information culture of all parties involved in this process.

It is necessary to consider the fact that public governance is a very conservative sphere that hardly adapts innovations. Due to historical reasons, this property is especially characteristic of the Russian system of public governance, for which digital transformation is not just a current trend, but to a greater extent an inevitable challenge of today. One more significant contradiction can be highlighted. The World Bank experts in the report "Digital Government 2020. Prospects for Russia" emphasize the fact that today "governments around the world are under double pressure: there is a constantly growing demand from the population for quality services, who want to interact with government agencies via the Internet as easily as with banking structures, online stores; at the same time, governments of all countries face the need to reduce administrative costs, improve the efficiency of implemented programs" [6, c. 5]. However, improving quality while reducing costs is an extremely difficult economic task, especially when it comes to advanced digital technologies.

Considering the digital transformation of public governance in the broad sense as a relevant phenomenon, in this article, in view of its limited scope, it seems appropriate to dwell in a problematic context on one of its key and leading (in the national dimension) aspects—the transition from "electronic" to "digital government" and the assessment of the current results of the introduction of digital technologies to

support the management processes in government at various levels, the emerging gaps in practice and the implementation of digital technologies.

3 Results

It should be recognized that during the period 2008–2017 Russia was able to make significant progress in implementing the concept of digital transformation by launching multifunctional centers and the Unified Portal of Public Services, a system of interagency electronic interaction of basic state information resources, and a unified information system of state and municipal procurement. According to estimates of independent experts, in general, the level of satisfaction of citizens with the quality of public digital services reached more than 85% during this period [6, p. 47].

Among the significant barriers to further development of the processes of digital transformation of public administration in Russia, experts point out the lag between institutional and technological changes. However, the system's perception of exclusively technological innovations without institutional change leads to superficial, fragmented changes. The most important tasks of transformation are: "platform independence, mobility orientation; design of services on the basis of the national digital platform, operating the unified data for sharing in the public sector and ensuring their cyber security, confidentiality, improved analytical processing and monitoring" [5]. These tasks have a relatively promising, but still largely declarative character, as their implementation is currently facing significant difficulties in real practice, which, among other things, is due to the already noted desire of the government system to conserve the current state and the methodological tools used. In this regard, the transition from established management methods to innovative digital technologies should be supported and coordinated at the highest level: at the national level—by the Deputy Prime Minister for Digital Transformation, acting as a kind of "chief architect" of the federal system, at the regional level—by the governor or vice-governor. However, such specialists should act as experts in the field of digital transformation (CDTO, Chief Digital Transformation Officer) in order to develop an adequate strategy, algorithmize the step-by-step activities and coordinate them with the appropriate responsible officers in charge of data handling, implementation and use of technologies and analytics. Unfortunately, Russian senior management personnel do not always meet these requirements.

One of the key challenges for the development of digital government is to "bring data, information and services together on one digital portal" [3]. It should be noted that in recent years our country has created integrated digital platforms at the federal level, comparable with similar models in leading countries. (The Common Government Services Portal, integrated since 2015 with the Unified National System of Identification and Authentication of Citizens, Unified Federal Public Procurement Portal) [7, p. 27]. Nevertheless, it should be noted that the implementation of the national program "Digital Economy" [5] has increased in recent years, according to

experts' estimates [7, p. 28], the degree of risks to the national (economic) security of the country [5]. Thus, by the end of 2018 the value share of foreign software purchased by state authorities decreased to 50%, and by the end of 2020 its reduction is planned at the level of 30%. However, it is not yet possible to completely abandon such procurement on the basis of import substitution policy: the level of fundamental and applied scientific developments, their active implementation to achieve technological independence in Russia does not yet meet the required level [8, p. 78]. According to the data of international ratings, the leading positions in the development of high-tech sectors (categories "electronics, computer memory", "software, information management"), which are the triggers for the development of state management functions, today are occupied by such countries as the USA, China, Japan, Germany, Great Britain, India. Russia is leading in these ratings only in the direction of "defense and security", which is an absolutely unsatisfactory indicator in terms of stimulating the digital development of public governance. It should be noted that at the global level, Russia is still inferior in the competition for factors that determine the creation of new advanced information innovative technologies, which in the conditions of low efficiency of the national innovation system leads to the "washout" of the country's remaining competitive potential—personnel, innovative scientific and methodological developments, promising ideas.

According to the tasks of advanced digitalization set in the program documents [3, 5], by the end of 2020 our country should have at least one, and by 2024 there should be 10 digital research platforms with participation of international partner centers [4]. However, in the Russian environment, there is still no structure for coordinating research in the digital economy that would ensure the harmonization of efforts of all actors involved in this process—representatives of executive authorities at various levels, business, higher education institutions, independent public organizations, research organizations, and society.

Among the key problems of the digital transformation of public administration remains a systematic methodological approach. More precisely, its absence. At present, despite the presence of the Ministry of Digital Development, Communications and Mass Media of the Russian Federation, various tasks of digitalization are dispersed among different departments, organizations and institutions, which, on the one hand, is quite logical, since the practice of the USSR and foreign countries suggests that it is impossible to create a single agency overseeing such issues in full. At the same time, the continuous transformation of the departmental structure of state institutions in our country, their merger, reduction, delegation of functions, causes inevitable deformations in the field of interagency coordination and control of the processes under study. In our opinion, a single, approved for a long period of time state institution in the field of academic science and management (for example, one of the leading centers at a leading university or scientific organization of the country with high research potential) could play an integrating role in this case, ensuring the unity of scientific and management and innovation space at a vertical level of integration (like, in particular, the Center for Strategic Development (CSR). Bringing together scientific and management capacities is crucial in this case. According to CSR experts, our country needs changes in order to quickly close the gap in the

development of digital transformation of public administration (compared to foreign countries), with further digitalization of all public services based on remote biometric identification on a single federal platform. The innovative nature of these proposals indicates that it will be extremely difficult to implement a digital transformation on their basis, which implies a transition to the a digital platform-state, because the existing management system, in Russian practice, as already stressed, seeks to maximize the preservation of its current state. And the set tasks, such as accumulation of Big Data and their operation in order to solve the tasks necessary for the population, are still innovative not only for practice, but also for science, considering the territory of the Russian state we are talking about a huge amount of such information, its defragmentation and distribution on an extremely significant number of levels—departmental, regional, municipal, local, etc., often demonstrating duplication, lack of data, inefficient and untimely exchange of data, etc.

Among the main barriers to activating the processes of digital transformation in public governance should be mentioned the lack of necessary legislative framework, excessively complicated legal structure regulating these issues, as well as insufficient level of professional competence of civil servants. The introduction of new documents implies the need for one-step amendment of a wide range of other interrelated legislative acts, which is not always possible at a full, comprehensive level and in a short time. A particularly characteristic proof of this statement is the fact that the program "Digital Economy" [5] provided for the preparation of a package of amendments to 50 existing Russian legislative acts, and the number of staff to implement these changes by 2024 should have exceeded several thousand people.

The leading tasks of the program "Digital Economy" [5] assume a sufficiently short time frame for the implementation of a number of fundamental changes in the public sector, to which this sphere is unable to respond in such a mode. In this case, it is possible to compare the public sector with business. While for the latter, digitalization is a vital requirement for competitiveness and profit growth, for the first, the role of digital transformation is not so obvious at the present stage: government bodies in our country practically do not compete with private companies for the consumers of public services, and the ineffectiveness of IT services created by them does not lead to bankruptcy of government organizations, their services still remain in demand in the absence of an alternative or ignorance of its citizens.

The results of inspections of the Accounts Chamber of the Russian Federation confirm that, despite the announced transition to a new stage of digital transformation of public administration, the main objectives of the system of coordination of measures aimed at digitalization in our country as of 2010 have not been achieved [9]. The assessment of experts of the Accounts Chamber in 2018 also revealed a number of significant violations, in particular, the "excess of expenditures over the amount of budget subsidies allocated for digitalization; insufficient accounting of information costs in the course of government procurement", etc [10]. So far, insufficient development of IT legislation in the Russian environment also leads to violations related to the creation of digital systems by government agencies at the expense of budgetary funds in the absence of any targets and standards. At the same time, the

cost of such a system is to a greater extent regulated by the assessments of contractors—market players, which leads to unreasonable overestimations. And these are not the only legislative gaps that lead to disproportions and deformations in the idea of digital transformation of the public sector. Although their list already indicates the significance and complexity of the gaps observed.

4 Conclusion

Therefore, the analysis makes it possible to state that in Russian practice digital approaches to the transformation of public governance are at the stage of active development and scientific reflection. However, in domestic conditions, it is rather natural to talk about the initial stage of these transformations, despite the fact that program documents in the periodization of 2018–2020 define this stage as a "stage of development" (which implies the formation and stable functioning of the necessary institutional framework and successful national approbation of methodological mechanisms and tools). The conducted research allows to draw a conclusion that conditions for achieving horizontal integration in the field of new quality of public governance based on digital technologies have not yet been sufficiently formed in Russia. Our country's further transition to a higher quality stage of transformation is hampered by a large number of risks and barriers, including those related to historical factors. Among the key problems hindering the digital transformation of management in the Russian environment are: the lack of strategic planning of IT architecture and distribution of state powers at the vertical level, within agencies and at the interdepartmental level, a clear legal regulation of these processes; inefficiency of budget expenditures for maintenance of the state apparatus and performance of functions; insufficient level of digital competences of civil servants correlated with a high level of complexity in management and budget planning of digital projects; institutional conflict of interests between state customers of digital projects and IT companies, resulting in the implementation of protection policy; lack of culture of interaction with digital technologies both at the level of state apparatus representatives and the Russian public. At present, in domestic conditions, it is more a question of testing the model of "service management" and a rather unstable transition to this concept in practice. To a great extent in this case it is the brisk pace of implementation of the planned activities, their scale and significant resource regional differences, departmental inconsistency, decentralization of efforts that influence the situation. Therefore, in today's conditions it is obvious that without a systemic modernization of administrative processes, without a fundamental reorganization of the work of the entire Russian state apparatus and a renewal of the mentality of its civil servants, without a transformation of the historical traditions of its formation and functioning, massive return on digitalization in Russia with a transition to the model of "united government" is unlikely to be expected in the near future. The "vertical" of outpacing innovations cannot lead to qualitative changes without the formation of a sustainable and gradually updated framework of the system in its horizontal dimension, which

requires not formal, but methodologically sound and understandable and stepwise implementation of agreed "road maps" not only at national, regional and other, lower levels. It also seems necessary to remove technological and legal restrictions for the digital transformation of public governance, to balance them; to increase investment of technological infrastructure at the expense not only of the state, but also of business, to continuously monitor gaps that arise in practice in order to make changes to the current legislative and theoretical-methodological foundations and their consolidation into a single system.

On the Issue of the Size, Prospects and Purpose of the Digital Economy

Yana S. Matkovskaya

Abstract The article **aims** to identify the size, prospects and purpose of the digital economy. Based on the methodology of analysis and synthesis, structuring of scientific positions using a systematic approach, abstract and logical types of analysis and analysis of statistical data, the author reveals the problem of the need to form a system of special knowledge about the essence and principles of digital economy functioning, which should be formulated by specialists in the basic and applied economic sciences and allow to create a basis for a systematic scientific-based multiparameter study of the digital economy continuum. However, the study shows that the digital economy, including its digital segment, shows a slower growth than previously expected and predicted. There is also a lag in the rate of development of the biotechnology industry. Yet, this does not call into question that the digital economy will develop at a faster pace in the near future. **The result** is an empirically based conclusion that, while the actual size of the digital economy is small relative to the size of all world production, the growth rate of digital technologies is exponentially increasing, expanding the space of the digital economy. For quality transformation, the underlying digital technology needs socialization, which implies the development of the technology itself, its size and acceptance by society. As a result of socialization, the most important general purpose of the digital economy—to meet the needs of consumers, and its special purpose—to contribute to the development of human capital, improve the quality of life of individuals, countries and the entire population of the planet, as well as reduce the uneven development of regions of the planet and economic sectors, should be fulfilled.

1 Introduction

To lead an argumentative discussion, to give an adequate scientific and methodological assessment of the so-called digital economy, and most importantly, to create conditions and institutional infrastructure for its development in the current conditions and for the future will be possible only when economists learn to understand well what digital economy is. Today, the digital economy is presented as a continuum formed as a result of the regularities of scientific and technological progress, MNC's financial interests and the needs of various consumers. Meanwhile, as a self-developing system, the digital economy in general can be considered as a new form of market self-organization [1, 2].

2 Methodology

The research methodology is based on the results of preliminary studies of the author and is based on the methods of analysis and synthesis, which allowed both to group the points of view of various researchers on the problems of digital economy and to make synthetic conclusions related to the identification of prospects and purpose of digital economy, caused by the need to implement its functions. The method of structuring of scientific positions is connected not only with revealing of system of digital economy definitions, but also with formulation of the problems facing researchers and connected with working out of positions and directions of research not only digital, but also all modern model of economic management. Statistical analysis using predictive models substantiates quantitative prospects of digital economy development, while abstract and logical analysis allowed to solve qualitative problems integrating conclusions of empirical and logical analysis.

3 Logical Analysis of Formation of the Economic Knowledge System and Ideas

The existing urgent need for the formation of a special knowledge system is dictated not so much by the presence of a significant number of definitions of this phenomenon as by the insufficiency of systemic economic concepts. Economic knowledge must not only define the essence of the digital economy, but also have the capacity to form future processes and reality. This knowledge should be based on monitoring the process of its institutionalization so that it can subsequently form multiparameter and non-monospatial models of its functioning. This is a long process and economists must be involved. While calling for this kind of discussion, there are several important points concerning the digital economy that are relevant for economists: there are several important aspects to know about the digital economy.

Firstly, each researcher should develop a position on how to view the digital economy: as an alternative to the analogue economy or as a dominant idea transforming analogue world.

Secondly, it must be understood that there are differences between the "digital economy", "digitalization of the economy" and "digitalized economy". It must be said that the introduction of the concept of "digital economy" is ascribed to different researchers. But it is very important to understand that the definition of the digital economy as part of economic production carried out through digital technology proposed by Bukht and Heeks [3, 4] was supported by Beerpoot; it is a business model based on digital goods or services [5, 4, p. 5]. Manyika and his co-authors are known to have the same viewpoint [6, p. 5, 7]. Brynjolfsson and Kahin take a different view—they propose to consider the digital economy as encompassing everything that is produced in the digital economy [8, 4, p. 5], while Knickrehm and his co-authors define the foundations of the digital economy as a set of equipment, special digital goods and services, digital skills [4, 9].

Thirdly, there is a need for a clear structuring of what is now considered to be the digital economy (Blockchain, Big Data analysis, artificial intelligence, 3D printing, Internet of Things, Automation & Robotics, cloud computing [4, p. 5].

Fourth, it is very important to understand that there are differences in the formation and functioning of value chains in the digital economy and the way added value is formed. These are chains that can be formed separately (blockchain technologies) or exist in parallel. And this is already happening everywhere: through digitalization, companies and their consumers exist in two spaces—the world of things and the digital world. In general, all the elements except the blockchain technologies that make up this digital economy are created to serve the economy, to create goods and services and to promote and consume them digitally and/or in a traditional way. Only the blockchain exists today separately from the real world, although within the rules of traditional economy aimed at receiving profit/minimizing transaction costs.

Fifth, there are many new problems with data ownership and the identity of beneficiaries.

Sixth, in the digital economy, both the impact and value of the network effect are increasing.

Seventh, new markets are forming and one of these markets is the Data Market. Preliminary estimates of the scale of this market are such that, for example, this Facebook unit has contributed to an increase of $5.8 billion in GDP [4, p. 70, 10] and similar Google centers brought $1.3 billion and created more than 10 thousand additional jobs in the United States of America [7, 11, p. 70], which is reflected in Fig. 1.

In fact, the E-commerce market has a steady upward trend. This is reflected in Fig. 2.

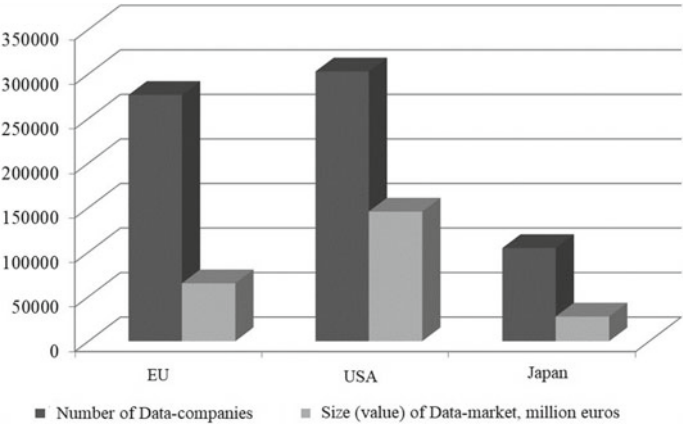

Fig. 1 Data market in individual economies. *Source* compiled by the authors on: [6, 7, p. 70]

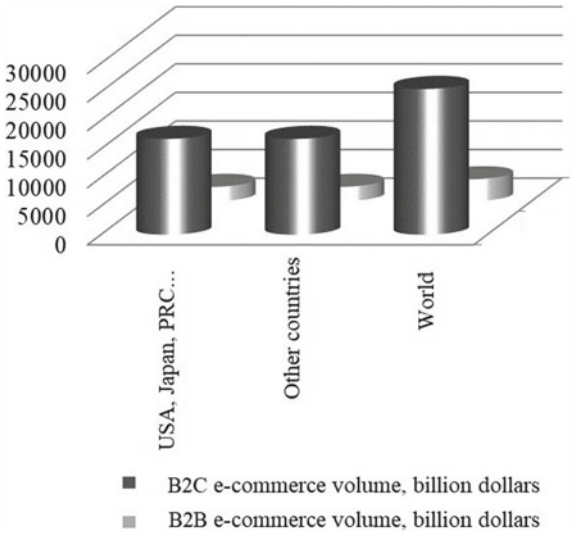
Fig. 2 B2B/B2C ratio in 2017 in the countries with the highest e-commerce development. *Source* compiled by the author on: [7, p. 15]



4 Quantitative Analysis of the Size of the Digital Economy

With regard to the size of the digital economy, it should be emphasized that, in virtually all reviews of its development, data transmission rates are among the major achievements. For example, the UNCTAD Digital Economy Report 2019 (by the way, earlier this annual report was called the Information Economy Report) points to the increase in data transmission speed as the main evidence of the growth of the digital economy. Thus, in 2017 the world Internet traffic already reached 46,000 GB per second, and in 2022 it will reach the level of 150,700 GB per second. Moreover,

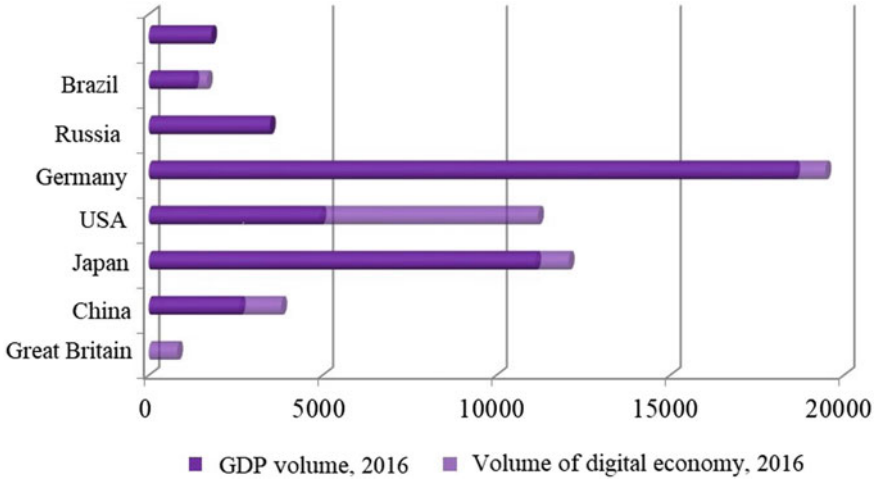


Fig. 3 Share of digital economy in GDP of leading countries of the world in 2016, billion dollars. *Source* compiled by the author [14]

an increase of 1507 times compared to 2002 is projected [7, p. 10] (100 GB per day in 1992). But the question arises, to what extent these dynamics solves the issues of economic development and whether this growth will influence the solution of the significant and actual for economic activity task – incompleteness and asymmetry of economic information. The growth of cross-border data flows (CBDF) is also predicted. According to McKinsey, the period 2005–2017 saw an increase of more than 140 times (5 and 704 terabits per second) [12]. In turn, the forecast of "The Boston Consulting Group" promises to achieve the size of the digital economy of the volume of $15 trillion by the mid-30s [13]. And what are the prospects (reserves) for the growth of the digital economy in GDP? Figures 3 and 4 show the data for 2016 and the forecast year 2021.

The lion's share of digital economy belongs to two countries – the USA and PRC: the value of market capitalization is the following – 70 digital platforms of these countries make up to 90%, including 68% of the USA, 27% of PRC and Asia, 3.6% belong to Europe, 1.3% to Africa and 0.2% to Latin America. 75% of all patents related to blockchain technologies, half of the world expenses for the Internet of Things, just under 1/3 of the cloud computing market are owned by the USA and PRC [7, p. 10]. However, in terms of colocation data centers, the leader is the United States—40%, while China owns only 2%. The total number of such centers is 4422 [7, p. 12].

However, half of the world's economic activity is offline, only 20% of people in developing countries have access to the Internet (are online), and there is a serious gender gap among digital users in the poorest economies [7, p. 10].

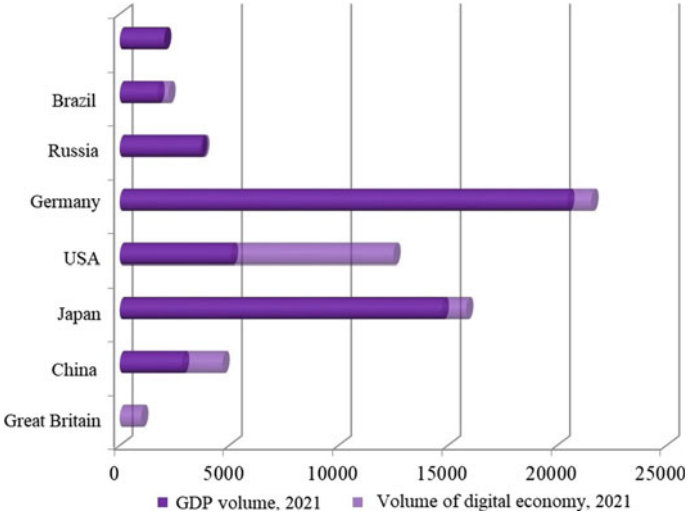

Fig. 4 Ratio of contribution of digital and analogue economies to GDP in 2021. *Source* compiled by the author [14]

Artificial intelligence and machine learning, according to some projections, are expected to reach $13 billion by 2030, which will increase world GDP by 1.2% [7, p. 8].

Figure 5 generally shows that the digital economy is not growing as fast as expected. The growth of innovation in this sector, as can be seen from [15], is taking place within the framework of global trends, and is even lagging behind

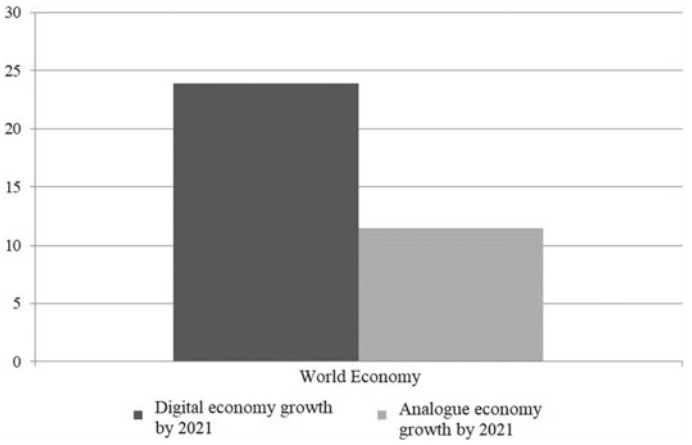

Fig. 5 Growth of digital economy and analogue economy by 2021. *Source* compiled by the author [14]

other advanced industries, such as biotechnical industry. But this does not mean that the digital economy, or more precisely the sectors it includes, are not in demand by mankind, but only that the digital economy is part of the economy designed to digitize economic processes, optimize (saturate) the existing ones and form new value chains. A really important achievement of the digital economy is considered to be the formation of a new value chain—"data value chain", as well as the formation and operation of digital platforms.

5 Results: Conclusion About the Prospects and Purpose of the Digital Economy

As it becomes clear from the above research, which is a continuation of a number of the author's works on the development of digital economy, that it is not appropriate to consider digital economy separately from other factors of the world economy development. All technologies created in the digital economy should be subordinated to the main purpose to meet people's needs and develop human capital. That is why we cannot help but support the developers of the Global Innovation Index in 2019, who are completing their research on innovation development by examining progress in healthcare as a result of the impact of digital technology [15]. Moreover, the relationship between R&D and the growth of the human capital index should develop and have some positive dynamics in terms of improved quality and increased life expectancy, which should be ensured not only by the development of digital technologies, but also by changing attitudes towards lifestyle, increasing access to healthcare and medical services. Thus, the development of digital technologies is not as important as the benefits they should provide humanity with.

6 Conclusion

The digital economy contains a great social, economic and cultural potential, called to develop a social and economic system, which, provided the development of scientifically sound economic knowledge and conceptual positions based on the development of fundamental concepts generated by economic science, will create conditions for the transition of mankind to a new level of socioeconomic development, in which digital technological innovations will not only solve production problems, but also the problems of development of mankind and its economic and social life ecosystems, ensuring better quality of life and habitat.

Digital Transformation of TPP Control Systems: Transition to an Intelligent Equipment Life Cycle Management Model

Valentin Ya. Afanasiev, Eugene P. Grabchak, Eugene L. Loginov, and Sergey V. Mischeryakov

Abstract The article discusses the intelligent information-analytical technology implemented in the operation of thermal power plants, based on the capabilities of multi-agent analysis of the state of each item of equipment in a single unified digital model of thermal power plants, when the system signals in advance about the need for equipment repair. The analysis includes the study of indicators characterizing the technical condition of equipment (using calculation models for planning the TPP operation mode) with the introduction of a virtual model for managing the equipment life cycle to determine the optimal type, composition and cost of technical impact on the equipment. At the same time, it is proposed to use a system of uniform standards, a unified model, unified identification principles based on a unified ontological model of subject activity for the transition from scheduled preventive repairs (SPR) of facility equipment to repairs as it is possible to generate scenarios of technical impacts on equipment (agent modeling) event-driven behavior): continued operation, repair, replacement, technical re-equipment or reconstruction. The article presents approaches to the formation of monitoring technology that ensures the construction of unified accounting systems for equipment operated at electric and heat power facilities, the improvement of their technological parameters and characteristics in relation to the assessment and forecast of the technical condition of production equipment based on monitoring data, statistics of defects and failures to determine the optimal type, composition and cost of technical impact on equipment that allows directing

JEL Code L51

1 Introduction

In the Russian energy sector, in connection with the digital trends of the transformation of information management systems, intellectual information and analytical technologies implemented in the operation of thermal power plants (TPPs) are becoming more and more in demand [1, 2]. The construction of modern digital systems for identifying fixed assets operating at electric and heat power facilities, and optimizing their controllable parameters and characteristics is being actualized [3, 4]. This is especially important, first of all, in relation to monitoring the technical condition of the equipment of thermal power plants, which is significantly worn out and has developed standard operating periods [5, 6].

Despite the increasing number of developments in this area, there is a need for innovative technologies for monitoring the technical condition of TPP equipment for the transition from scheduled preventive repairs of energy facilities to "repairs according to the technical condition" [7, 8]. Aging and deterioration of TPP equipment determine the need for predicting the optimality of technical impacts on components and mechanisms: continued operation, repair, replacement, technical re-equipment or reconstruction, taking into account the occurrence of degradation processes in the equipment array [9–14].

2 Methodology

2.1 Create a Digital Management Environment that Supports Risk-Based Management Using Digital Technology

To determine the rational composition and the minimum cost of technical impact on equipment that allows you to direct the flow of events in accordance with the conditions specified by the availability of financial resources for these purposes, it is advisable to use calculation models for planning the operation of thermal power plants based on monitoring and analysis of the state of functional units in a single

digital thermal power plant with verification models to clarify its relevance to events in a real environment [15].

It is proposed to create an ecosystem that provides risk-based management based on digital technologies to assess the technical condition of the equipment of thermal power plants using digital models of technological processes, physical systems, objects and products for a rational composition and the minimum cost of technical impact on the equipment at all stages of equipment operation. In this case, the operation of equipment using calculation models for planning the TPP operation mode (with planning future synchronization operations, forecasting to eliminate the causes of their delay) based on monitoring and analysis of the state of each functional unit of the equipment in the digital TPP model is considered by the authors as a dynamic combination of current and overhaul with taking into account various categories of indicators of reliability and working life of equipment allocated on the basis of direct or indirect to participate in the reduction of the flow of failures, failure rate and longer trouble-free operation.

To control the processes of equipment operation in the monitoring system of the technical condition of the equipment of thermal power plants with the introduction of a virtual model for managing the equipment life cycle, when the system signals in advance about the need for equipment repair, it is proposed to use agent analysis and modeling technologies.

It is necessary to establish an analysis of reliability indicators and operating time of equipment for the transition from the maintenance and repair of equipment of facilities to repairs according to their actual state (with testing maintenance strategies), which require predicting the level of equipment wear and the probability of failures (oriented graph with vertices—states and pseudo-states of the equipment) [16, 17].

For this, the technical condition of the equipment of thermal power plants is analyzed (based on a virtual model of equipment life cycle management taking into account the course of degradation processes in the equipment array) using standards, a unified model, identification principles based on an ontological model of subject activity with support for risk-oriented management with using digital technology.

On this basis, it is assumed during the monitoring and monitoring of the state of equipment elements in the digital TPP model with model verification to clarify its compliance with events in the real environment—within the calculation models for planning the TPP operation mode—software determination of the technical condition of the equipment corresponding to the target settings to prevent situations with non-performance or improper repair. That is, the analysis and identification of failures and their consequences, the intensity of failures is necessary to increase the period of trouble-free operation based on the use of the index of the technical condition of the equipment, aimed at determining the rational composition and minimum cost of technical impact on the equipment, allowing you to direct the flow of events in accordance with the conditions specified by the availability of financial resources for these purposes, taking into account indicators of reliability and working life of equipment.

2.2 The Structure of the Description of the Analyzed Data

Descriptions of structured databases of the technical condition of equipment, with support for risk-based management using digital technologies, are presented in a standardized manner and contain data on the results of equipment operation in the technical condition system of the equipment of thermal power plants. End-to-end digitalization creates the basis for building systems for identifying equipment of electric and heat power facilities, monitoring their controlled parameters and characteristics.

Identification, setting the structure of information in the database is one of the components of ontological modeling. It assumes a set of terms (TBox—from the Terminology Box), a set of statements (ABox—from the Assertion Box), i.e. the values of specific properties for specific individual objects, specific relationships between them (this part of the model describes specific facts).

On November 15, 2019, Russia adopted GOST R 58,651.1—November 15, 2019 "Information model of the electric power industry. Basic Provisions" and GOST R 58,651.2—15.11.2019 "Information model of the electric power industry. The basic profile of the information model", which determine the requirements for profiles of information models and the organization of information exchange in the electric power industry and establish the composition of the information model to ensure an unambiguous interpretation of the transmitted and received data by all participants in the information exchange in the electric power industry. The adoption of GOSTs gives an additional impetus to the work on the development of unified industry classifiers of the main technological equipment, the formation of a single information model of the electric power industry.

The dynamics of the flow of failures, the intensity of failures based on monitoring and analysis of the state of an equipment item in a digital TPP model is studied using a special unique code that is virtually attached to a unit of equipment (group).

Descriptions of identifiable parameters of the failure flow, the failure rate associated with the execution of design models for planning the operation mode of thermal power plants of one type are grouped into virtual information classes of data on the operation of the equipment in the system for analyzing the technical condition of units of technological equipment (TEU) of thermal power plants taking into account the phases of its life cycle.

This creates the opportunity to analyze heterogeneous technical and economic data obtained from various information sources to determine the rational composition and minimum cost of technical impact on equipment using standards, a unified model, and identification principles based on the ontological model of production activity.

On this basis, access to the formation of scenarios of technical impacts on equipment (agent-based modeling of event-driven behavior) is carried out: operation, repair, modernization, replacement, taking into account the occurrence of degradation processes in the equipment array, where the analysis of the parameters of the operation processes allows us to analyze the movement of resource packages,

highlight a changes in the group of indicators of reliability and operating life of equipment and their characteristics for the development of management recommendations within interactive communications utilities and regulatory agencies.

The systematics of indicators of reliability and operating life of equipment is presented during the analysis of normal and emergency operational dynamics for the transition from the maintenance and repair equipment of facilities to repairs according to their actual condition (with testing maintenance strategies) that require adjustment based on predicting the level of equipment wear and the probability of failure (oriented a graph with vertices—states and pseudo-states of equipment), i.e. a predictive analysis of the technical state of production assets on the basis of monitoring, failure analysis of statistics.

Participants in monitoring the state of equipment when analyzing the flow of types and the intensity of its failures, using digital models (doubles) of technological processes, complex technical systems (CTS), objects and functional units, can identify the causes of events based on the analysis of explicit and implicit cause-effect relationships during predictive analysis of the technical condition of production assets based on monitoring, statistics based on monitoring, analysis of failure statistics in each functional unit of a technological unit one equipment (TEU) in a single, unified digital model of TPP with verification model to refine its matching events in a real environment.

2.3 Determination of Resource Efficiency of Current and Overhaul

Clustered indicators of the state of production assets based on monitoring, predictive analysis of the technical condition are determined during the monitoring of normal and emergency operational dynamics with access to the resource efficiency indicators of current and overhaul with the expansion of the range of any equipment reliability and operational life indicators available for analysis. The data package selected by the monitoring operator for predictive analysis of the state of production assets based on monitoring, statistics on types of failures, carries information on the resource efficiency of the current and overhaul repairs in the time and object-parametric dynamics.

Classification, that is, the inclusion of each object in one or more classes, clusters is an integral component of ontological modeling. The term “class” in information models means a certain symbol (information signal), which is used to generically denote a collection of objects. Conceptualization in models and classification in information systems are needed in order to be able to formulate knowledge and build logical conclusions, in particular, on the resource efficiency of technical influences.

The calculated interpretations of the resource efficiency of the current and overhaul based on monitoring data, statistics of defects and failures allow us to determine the “optimal type, composition and cost of technical impact on the equipment” [18, 19].

Analysis of the state of production assets based on monitoring, statistics of types of failures and their consequences, identifying the inefficiency of a particular position within the calculation models for planning the TPP operating mode, allows you to individualize the characteristics of the technical condition index of a particular unit of equipment with the formation of clarifying conditions for the implementation of current and overhaul (with planning future synchronization operations, forecasting to eliminate the causes of their delay).

It also helps to determine the compliance of the operation process with regulatory requirements [20, 21]. The results of the analysis allow government departments to develop recommendations on adjusting the programs for current and capital repairs of thermal power plants taking into account the tariff-price and resource dynamics in relation to the production and sale of electricity and heat [22, 23].

3 Results

Thus, to reduce the flow of failures, the failure rate and increase the period of trouble-free operation of TPP equipment, a method is proposed for predictive analysis of the technical condition of production assets based on monitoring data, statistics and defects using a multi-aspect interpretation of the systematics of reliability indicators and operating life of equipment based on digital technological doubles processes of complex technical systems, objects of electric and heat power engineering and technological units of equipment and other production assets.

4 Conclusions

The proposed monitoring technology provides the construction of typical systems for predictive analysis of the state of production assets of electric and heat power facilities, improvement of their life cycle parameters and characteristics based on monitoring, statistics of types and failure rates to determine the rational type, composition and minimum cost of technical impact on them, which allows directing the flow of events in accordance with the conditions specified by the availability of financial resources for these purposes. An automated analysis of the indices of the technical condition of each unit (node) of equipment is carried out and scenarios of technical impacts on the equipment (agent-based modeling of event-driven behavior) are generated: operation, repair, modernization, replacement or reconstruction (with the planning of future synchronization operations, forecasting to eliminate the causes of their delay) with the specification of basic characteristics, when the system pre-signals the need for equipment repair, using x models of planning the operation of TPPs.

Condition and Prospects of Innovative Development of the Economy in Kazakhstan

Ardak A. Nurpeisova, Laila K. Smailova, Bibigul Zh. Akimova, Elena V. Borisova, and Shakizada U. Niyazbekova

Abstract The article reviews the problems of innovative development in Kazakhstan. Today, the sphere of innovation is the formation of competitive advantages of any national economy. The weakest element in the number of factors that ensure the country's competitiveness is innovation. The main indicators of innovative activity of enterprises are shown and considered problems of the country's scientific and technical potential and steps to overcome them. The creation of a national innovation system and the development of innovative strategies and programs have become key tasks for the Republic of Kazakhstan in creating a knowledge economy. The study found that the existing system in Kazakhstan's condition of innovation infrastructure is imperfect. Notwithstanding numerous initiatives in recent years, Kazakhstan's innovation system is still in its infancy in many ways. **Results**: the terminological apparatus of the "innovation" concept is revealed. The main reasons for Kazakhstan's delay in innovation are identified. Considered ways to solve problems by increasing the proportion of employees engaged in the sector of high-tech services and high-tech industries; increasing government funding for Research and development (R&D); increasing the number of intellectual property patents. Kazakhstan needs to move from the current response to the challenges of innovation development to its long term planning.

Keywords Innovation · Economic development · Innovation activity · Global innovation index · Competitiveness

JEL Codes O10 · O20 · O30

1 Introduction

Innovation has been recognized as a very important driver of renewal in today's rapidly changing and competitive business environment. Innovation is a process aimed at creating or developing a new product, regardless of the type or degree, that increases the company's profit and strengthens its position in the market. Competition is the main reason for firm innovation, so different firms innovate in various ways. The understanding of "innovation" is widespread and depends on why and where it is located. Innovations are developing in companies, organizations, institutions, or systems. To succeed and create value, innovative companies, organizations, and other establishments must evaluate the tools and resources to achieve the expected results. Economic and technological innovations have changed our lives for the better.

2 Background and Methodology

The experience of successful developing countries shows that science and technology research policies are well integrated into national development strategies and match with institutional and organizational changes, which can improve productivity, increase firm competitiveness, support faster growth and create jobs. To achieve this goal in the policy, it's needed to take into account the specific characteristics of innovation in developing countries [1].

Innovation is one of the most important components in the modern economy, it's a "stepping stone" to improving the quality of life and a stable and environmentally safe future. Innovation is an important part of social and economic life and human activity in all its forms [2]. Currently, there are more than a hundred different definitions and interpretations of the term innovation.

In recent decades, innovation has become one of the most intensively studied topics in Economics and management. The works of several scientists are devoted to the problems of innovative development of the economy, the innovative activity of industrial enterprises and implementing innovations: Drucker [3], Schumpeter [4], Twiss [5], Kondratiev and Wolfgang [6], Damanpour and Aravind [7], Cohen [8], Chesbrough [9], Weidlich [10]. Such scientists have devoted their works to innovative processes: Semenyuk, Sabina, Sadykova, Arynov, Beloussova, Niyazbekova, Suleimenova [11], Niyazbekova, Bekbenbetova, Borisova, Dzholdosheva, Rasulya [12], Baigireyeva, Niyazbekova, Borisova, Ivanova [13], Nurpeisova, Niyazbekova, Dyussembayeva, Seitova [14], Imangozhina, Satenova,

Niyazbekova, Zuyeva, Issayeva [15], Niyazbekova, Zuyeva, Borisova, Anzorova, Novikova [16], Sivash, Burkaltseva, Kurianova, Nekhaychuk, Stepanov, Tyulin, Niyazbekova [17].

World practice shows that the development of innovations is not only the main tool for improving the competitiveness of an individual enterprise, but also is a serious incentive for the economic development of the country.

3 Discussion and Results

In the annual competitiveness rating compiled by the Swiss business school IMD, out of 61 leading economies in the world in 2019, Kazakhstan took the 34th place and rose on four steps. Russia received 70,4 points out of 100 possible and rose from 40th to 38th place. The rating leaders are the United States, Singapore, Sweden, and Denmark.

According to the 2019 report of the Global innovation index, the leading innovator countries are Switzerland, Sweden, the United States, and the Netherlands. By the results of the Global competitiveness index in 2019, Kazakhstan took 79th place (in 2018, it took 74th place) among 129 countries, between Bahrain and Oman, and Russia took 46th place. Innovative activity of Kazakhstan's enterprises is at a low level of 10,6%, the percent of innovative products is 1,91% of GDP (Table 1, Fig. 1). In Kazakhstan, R&D expenditures in percentage of GDP were: 2015– 0,17%, 2016– 0,14%, 2017— 0,13%, 2018– 0,12%.

Percentage of innovative products (goods, services) to GDP (Fig. 1).

According to Table 2, the largest number of enterprises that performed research

Table 1 Main indicators of enterprises' innovative activity

	2014	2015	2016	2017	2018
Number of enterprises, units	24,068	31,784	31,077	30,854	30,501
among them: having innovations in all types of it, units	1,940	2,585	2,879	2,974	3,230
levels of innovation activity	8.1	8.1	9.3	9.6	10.6
among them: having innovations in all types of it, units	1,303	1,781	1,743	1,770	2,019
level of activity in the field of innovations in product and process innovations, in percent	5.4	5.6	5.6	5.7	6.6
Percentage of innovative products (goods, services) to GDP	1.46	0.92	0.95	1.55	1.91
Share of innovative products (goods, services) of manufacturing enterprises in the total volume of industrial production, in percentage	2.61	1.80	1.81	3.18	3.78

and development, education and health and social services, then goes manufacturing, the smallest number of enterprises in the building sector.

In 2018, internal R&D expenditures totaled KZT 72224,5 million, increased by 10%, while in 2014 this figure was equal to 66347,6 million KZT (Table 3).

Business innovation remains weak and not diversified. In 2015, the business sector invested approximately 40% in R&D, which is quite low by international standards, especially compared to OECD countries, where the average is 68%, and below the level of countries such as China or Malaysia [18]. Moreover, this low indicator has to be considered in the context of a low level of R&D spending in General: if you look at it in proportion to GDP, the gap will be even larger. Government funding for R&D is also not sufficient. In this case, Kazakhstan is similar to other Central Asian countries, where there is also a low level of investment in R&D.

Table 3 Sources of funding for internal R&D expenditures KZT million

	2014	2015	2016	2017	2018
Domestic costs R&D	66,347.6	69,302.9	66,600.1	68,884.3	72,224.5
Including own funds	19,858.3	25,356.6	26,388.8	28,187.6	34,251.0
Republican budget	43,052.6	40,424.7	35,186.3	35,338.3	31,635.5
Local budget	290.9	294.5	254.2	641.7	510.3
Foreign investment	489.6	1,254.6	1,018.7	272.3	x
Other funds	2,656.2	1,972.5	3,752.1	3,444.3	3,904.4

Source Statistics committee, Ministry of National Economy of the Republic of Kazakhstan

Despite a certain potential in human capital and research, Kazakhstan's innovative development is low. Low innovative development of enterprises, weak patent activity, science continues to function within the traditional (industrial) model, separated from business and education. It is necessary to develop competitive mechanisms that stimulate not only the supply but also the demand for innovations.

Perhaps the most significant obstacle to business innovation in Kazakhstan is the low demand for innovative products [19]. Local businesses do not invest enough in non-technological innovations, paying little attention to changing their processes and marketing strategies.

Kazakhstan's innovation infrastructure is represented by 10 special economic zones (including 1 independent cluster Fund), 19 technology parks, 29 technology commercialization centers, 4 design bureaus, 6 international technology transfer centers, and 2 innovation clusters. According to the SWOT analysis, the innovative infrastructure existing in the Republic is in an imperfect condition. This is described by the low number of infrastructure links, their regionally and functionally unbalanced distribution, and the weak links between them. Other internal factors hindering its development include poor human resources, lack of methodological procedures for quality control, analysis, evaluation and forecasting of innovation infrastructure development, and immature infrastructure connections supporting the high-tech sector and a low level of integration of science, education, and production [20].

The number of results in research projects conducted in collaboration with production is limited, and the level of culture and supporting infrastructure for cooperation with the private sector is low. Despite the increased number of training courses for future entrepreneurs in universities, enterprises have a lack of specialists with managerial and entrepreneurial skills. The scarcity of initial funding is because of the low level of innovative entrepreneurship, lack of knowledge in venture financing, uncertain prospects for selling the investor's share in domestic financial markets, and the lack of options for financing projects at a later stage.

Compared to the population, employment in R&D is low by international standards, although there has been some recent growth. In terms of the number of research personnel, Kazakhstan is behind the average of the OECD countries or the Russian Federation, Malaysia and China; its number is about half of the average among countries with higher-than-average incomes, according to the World Bank classification [18].

It is reasonable to develop science, technology and innovation policies simultaneously with policies aimed at improving the framework conditions. More attention should be paid to new forms of innovative activity: clusters, technology parks, industrial zones, etc. It should be taken into account that not only real assets are important but also institutional and social interaction of all participants and an atmosphere of mutual trust.

During the years of independence of the Republic of Kazakhstan, formed the basic elements of the national innovation system. The National Innovation Fund, the National Center for Biotechnology, the Science Foundation, JSC "KazAgroInnovation", the National Information and Communication Holding "Zerde", Nazarbayev University, the National Welfare Fund "Samruk-Kazyna", the Kazakhstan Institute

of industry development, etc. Over the past decade, a lot of attention has been paid to improving the quality of implementation of educational and research programs by merging universities and reorganizing their educational and scientific activities.

4 Conclusions

It cannot be denied that the government of Kazakhstan is doing a lot to solve the tasks set. The Council for technology policy under the Government of the Republic of Kazakhstan and the Specialized Institute for technology development were established to coordinate innovation activities in the country.

Currently, there are forming a wide range of innovative infrastructure: engineering offices, regional technological parks, venture funds, technology transfer centers, commercialization offices, adopted normative legal documents, provides the innovative grants, implement the project and venture funding, tax incentives [21].

Prospects in improving the innovation economy in Kazakhstan:

- increasing the proportion of employees in the high-tech sector services and high-tech industries;
- increasing government funding for R&D;
- increasing the number of intellectual property patents.

Another important step in this direction is the expansion of innovative financing tools. The tasks should include adequate financing of all investments and the availability of early venture financing mechanisms that would ensure the initial financing of high-tech enterprises. The R&D requirement for subsurface users must be properly implemented. The expected funds should be directed to R&D, bringing significant benefits to society, including outside the extractive sector. Besides, the restrictions on such applications (especially those related to external R&D) and ambiguities in the rules (expenses that qualify for benefits, and so on) that reduce the effectiveness of this requirement need to be reviewed.

Consequently, taking into account the above, eliminating several gaps in legislation in innovation and the implementation of additional stimulating regulations at the legislative level, will have a positive impact on the increased level of innovation activity in the country and create a favorable innovation environment.

Improving the System of Management and Coordination of State Policy on the Institutional Provision of Technological Breakthrough in the Russian Economy

Niyaz M. Abdikeev, Yuriy S. Bogachev, and Yuriy P. Kalmykov

Abstract Purpose: The article discusses the efficiency of state policy on the provision of a technological breakthrough in the Russian economy. Design/methodology/approach: Within the study, the authors have employed the methods of systemic, factor, functional, logical, comparative, and statistical analysis. On the back of the analysis, an integrated assessment of institutional and technological provision means of the Russian economy has been carried out. Findings: The authors have found out that the current system to manage and coordinate the performance of national projects does not pay due attention to inter-industry and interdisciplinary interaction, the achievement of sustainable demand for breakthrough technologies, products, and services, and development of a large-scale system for generation of scientific and technical knowledge. The authors have proved the need to coordinate the performance of national projects in the field of labor productivity, employment of the population, and science using network principles. It has been proposed to engage a coordination committee as the governing and coordinating bodies in the performance of these projects. The paper has established its functions and priority areas to improve the institutional provision of national projects. The authors proposed a mechanism of megaprojects as forms of executing national projects on the back of development institutions within a unified management and coordination system. Besides, the criteria for development institutions have been developed, a list of development institutions has been suggested and the structure of the platform for the generation of scientific knowledge and their transformation into innovations have been discussed. Uniqueness/value: The findings can be useful in executing national projects.

1 Introduction

The state policy on the institutional provision of the technological breakthrough in the Russian economy is not integrated. For example, the government program "Development of the Aviation Industry" [1] and "Strategy for the Development of Mechanical Engineering for the Food and Processing Industry in the Russian Federation until 2030" [2] stipulates the technological and economic development of these industries in Russia against the international level.

National projects that will speed up technological modernization of Russian economic sectors have been selected. However, it is not taken into account that the expected results cannot be achieved without productive inter-industry and interdisciplinary interaction and the establishment of mechanisms for their application in the economy. Thus, the system of public policy management needs the means to coordinate the performance of national projects. The options are presented below.

2 Methodology

The Strategy for Scientific and Technological Development of the Russian Federation points at the need for the full-fledged provision of transforming fundamental knowledge into breakthrough technologies, products, services and achievement of sustainable demand in the domestic and foreign markets [3].

Another important challenge of national project (NP) performance is designing a mechanism for adaptation of the results to the real economy. A critical factor of the competitiveness of technologies, products, and services developed within NP is a high-tech production base, which requires, among other things, the development of an institutional provision system.

However, the national project "Labor Productivity and Provision of the Employment" is not aimed at the above value-added chains. The main focus is on assistance to the programs to increase labor productivity at some enterprises with annual revenue corresponding to a certain criterion. The task is to lay conditions for enterprises to reach a steady rate of labor productivity growth by 5%. But the desired level of labor productivity in the domestic industry and the growth rate set forth by the national project lowers the chances of the Russian economy to take fifth place in 2024 by GDP with regard to the purchasing power index. The expected results of this project

do not meet the Decree of the President concerning the need to forge conditions for the technological breakthrough in the Russian economy.

Conditions for a fundamentally new level of labor productivity cannot be reached without large-scale generation of scientific and technical knowledge, accumulation of human capital and development of breakthrough technologies corresponding to the sixth technological wave and their adaptation to economic turnover.

Therefore, the performance of the National Projects "Labor Productivity and Employment" and "Science" should be coordinated.

The international experience shows coordination may be efficient under a network performance of national projects.

Therefore, in accordance with the current situation solving the problem of higher labor productivity is impossible without developing technologies of network organizational forms and their application in value-added chains, achieving a stable trend towards increasing demand for relevant products in the domestic and foreign markets.

When preparing a comprehensive modernization of the real sector of the Russian economy, it is necessary to coordinate the interests of various ministries and departments, the scientific and business communities in the development of major projects on the design of new competitive products.

It follows from the international case that only the body headed directly by top public officials (the case of France, Japan, Ireland, China, South Korea, etc.) can successfully fulfill a task. It is this body that can coordinate diverse interests and ensure the focus of resources and efforts on the efficient solution of a strategic task [4].

In this regard, it is reasonable to engage the Coordination Committee consisting of senior representatives of the Presidential Administration, Government, leading Russian companies, business associations at the federal level, and the expert community as the governing and coordinating body of the national projects "Labor Productivity and Employment of the Population" and "Science". The procedure for its constitution, purpose, objectives, and functioning should be stipulated in the Presidential Decree.

When working out the mechanism for adaptation of the national project achievements to the economy, one should bear in mind that one of the key factors affecting the sustainability of the socio-economic development of the national economy is the balance of the real economy sectors in terms of labor productivity and investment capacity [5]. As it is stated in the Industrial Development Report [6], the balance can be achieved and maintained through vigorous inter-industry communication of the real economy sectors with high-tech and mid-tech sectors of the processing industry. Moreover, the communication will be fruitful if their contribution to the total value added of the processing industry together with the gross product per capita in Russia, is over 35% [6]. However, it is markedly less than 10%, which is typical for countries with low income per capita [7].

Therefore, the conditions for sustainable development can be laid provided that the development of the above sectors will be outrunning. In this regard, the national project "Labor Productivity and Employment Provision" should focus attention on these sectors and work out an appropriate system of measures. Along with that, the

development of these processing industries can be stepped up only under a certain trend of demand for their products. This can be ensured by a significant investment in the real economy sectors, which ultimately will help to create conditions for a breakthrough in the technological and economic efficiency of the Russian economy in general. Therefore, a technological development program should be elaborated.

The above problems can be solved given a substantial development of staff potential both in qualitative and quantitative terms, but this can only be achieved under a network communication between leading scientists, engineers, product designers, and managers.

For the institutional provision of the Coordination Committee, the management system tools need to be adjusted.

International experience evidences [8, 9] that a megaproject can act as a toolkit. Within it, a chain of transformations of scientific achievements into end products to be consumed by economic agents and private households will be arranged through the above communication mechanism. A megaproject should be developed in each basic industry which we understand here as high-tech and mid-tech sectors of the processing industry [4].

For the development of megaprojects, coordination, and performance, development institutions are being established within a single system. Its structural elements are subsystems that help to solve the problems of industry development. The system management is hierarchical and based on the principles of all-around network communication. It comprises the Coordination Committee, the Institute for Strategic Planning and Coordination, development institutions, executive committees for the management of megaproject performance, and megaprojects.

The Institute for Strategic Planning and Coordination brings into accordance with the preparation and performance of megaprojects for a balanced technological development of the Russian economy.

The Development Institute is an organization aimed at solving systemic problems regarding the development of the real sector industries, enhancement of their competitiveness in the domestic and foreign markets in accordance with global trends (transition to the sixth technological paradigm, establishment of the production base of the real economy based on network organization of value-added chains, digitalization of the management system, international standards for environmental protection, healthcare, education, and housing sector). Within the Development Institute, an expert council is composed to select promising innovative projects relying on the internationally recognized developments of domestic scientists in the fields relating to the sixth technological paradigm. Specific mechanisms are presented in works by Bogachev et al. [10, 11]. The Development Institute coordinates the preparation of mega-projects for the technological development of basic industries through the cooperation of specialists, including scientists, designers, engineers, product designers, and top managers of leading companies in these industries.

The obligatory criteria for development institutions:

1. an indicative development plan of the Russian economy industry approved by the Government on the representation of the Coordination Council in accordance with the functional purpose of the development institution;
2. world-class expert capacity (experts have achievements internationally recognized developments in science, technology, education, and management);
3. the availability of budgetary and extrabudgetary resources at the ratio not lower than 1: 5[1]:
4. financial security (the ratio of borrowed capital and own funds);
5. high level of regulatory documentation. It is determined by the legislative rule as a means of problem-solving in the most suitable way. It has several functions [12]:

   (a) contains a socially useful purpose and objectives (of a social, state, regional, collective, and individual nature) arising out of it;
   (b) sets the parties and level of decision-making;
   (c) defines illegal actions in some situations;
   (d) directs at the choice of appropriate behavior options;
   (e) secures against possible production and economic risks.

The list of development institutions covers industry, information infrastructure, transport infrastructure, science, education, healthcare (human capital).

Monitoring and coordination of the megaproject performance are carried out by an executive committee consisting of top executive authorities responsible for the development of the respective economic sector, top managers of leading companies and high representatives of the expert community. Besides, the body coordinates the upgrade of the respective production base made of cluster production associations.

3 Findings

One of the sufficient conditions for the economic growth of processing industries is the development of a chain: a platform for the generation of scientific knowledge and their transformation into innovations—the production base for the batch reproduction of high-tech internationally competitive products—a system for marketing of manufactured products.

The platform for the generation of scientific knowledge and their transformation into innovations consists of particular stages for the development of complex equipment, as well as its constituent parts, with regard to the structure of the modern

[1]The Development Institute is functioning within a public-private partnership using budgetary and extrabudgetary funds. Each of the sources has an intended purpose. Budgetary funds are used for arrangement and pursuance of basic and applied research, and extrabudgetary funds—for the development of proof-of-concept (POC) technologies, the performance of tests, and organization of pilot and batch production following the world experience of using financial resources in ratio 1:5.

production chain. The stages fall in the competence of the integrator and first-level suppliers respectively in accordance with their duties.

To ensure the performance of the above platform, the government engages the internationally recognized scientists in the relevant fields of knowledge to design breakthrough technologies and high-tech competitive industries. Thus, a mechanism of communication between the academic, university and business sectors of science is being established using network administration principles.

Within the platform, a system of reproducing staff potential of science and industry is being built by means of cooperation between leading educational and scientific institutions and industrial companies.

In view of the foregoing, we have worked out the following suggestions.

4 Conclusions/Recommendations

Suggestions on the arrangement of a management system.

1. To build a hierarchical system of management and coordination of national projects "Labor Productivity and Employment" and "Science", based on network principles and composed of

   first level—Coordination Committee;
   second level—Institute for Strategic Planning and Coordination;
   third level—development institutions;
   fourth level—megaprojects;
   fifth level—executive committees for the management of megaproject performance.

2. To design a system to select promising innovative projects in development institutes on the basis of developments made by internationally recognized scientists in the fields relating to the sixth technological paradigm for mega-project detailing.
3. To shape a system of analytical centers in high-tech industries based on scientific and educational centers (SEC) for the development of sound recommendations on industry development areas [13].
4. To institute a system of state control over holding program activities for the development of high-tech industries.

Suggestions on communication between high-tech and traditional industries.

1. To establish a system of technological development of traditional industries through intensification of inter-industry communication with high-tech industries.
2. To develop a system to meet the needs of civilian sectors in high-tech equipment by the defense complex enterprises.

Suggestions on the knowledge generation system that meets the requirements of the sixth technological paradigm.

1. To design a means for the development of knowledge generation platforms and systems for their transformation into breakthrough technologies.
2. To conceive an efficient mechanism for the cooperation of the academic, university and business sectors of science to create high-tech competitive industries.
3. To establish a system of advanced training of skilled academic staff in the fields relating to the sixth technological paradigm.

Suggestions on the development of the staff potential in the domestic industry.

1. To institute a system of advanced training of skilled staff in engineering and industrial specialties to ensure technological breakthrough through cooperation with leading educational institutions.
2. To set up an industry staffing management system based on monitoring of proficiency level of employees in high-tech and knowledge-intensive sectors.

Suggestions on financial instruments to ensure a technological breakthrough in the economy.

1. To develop an interest rate system when granting credits for business development in high-tech industries with regard to risks arising out of a foreign-equipment production base.
2. To work out a mechanism to harmonize state support for high-tech processing industries, linking it with the development trend of respective segments of the domestic market.
3. To design a platform for leasing provision of domestic products and after-sales servicing of domestic machinery and equipment within the state support of the product export.
4. To amend the customs tariff policy towards favorable conditions for domestic manufacturers to promote high-tech products to domestic and foreign markets and provide for higher duties for the corresponding foreign counterparts.

Methodology of Analyzing the Effectiveness of Activities in the Conditions of the Digital Economy

Ulyana Yu. Blinova, Nadezhda K. Rozhkova, and Aigul Zh. Sultanguzhieva

Abstract One of the key areas of activity of each commercial organization is investment activity, which allows for updating the material and technical base, which requires significant financial investments. It's necessary to involve investments in the economic process to increase the production of goods. The global market economy provides many alternatives for capital investment and international capital integration. Moreover, the amount of financial resources that can be invested has a finite size. Active dissemination of digital technologies influences the investment activities. The digital economy involves the formation of an accounting and analytical system based on information technologies, which are interconnected and interdependent with electronic business. In the conditions of economic sanctions and limited financial resources, the expedience of usage of investments sets before the companies the necessity for implementing the digital information technologies, which bring economic profit. In the current economic situation, analysis of formation of a methodology of effectiveness of the investment activities in digital information technologies is one of the most important tasks of the modern economy. The purpose of the paper is to study the current state of digitization of the methodology of effectiveness of investment activities and to solve the main problems that hinder the digital transformation. In particular, investment projects are often implemented spontaneously, without defining clear goals and financial results. This practice isn't permissible in digital information systems. There are no indicators of the achievement of the goal of investment activity that characterize the uniqueness and individualization of the investment project. Along with this, the problems of information support for the

management of an investment project based on the introduction of modern information technologies, which can only be solved by developing effective methods for analyzing investment activities, are put forward. Based on an analysis of the effectiveness of investment projects, the article proposes the application of the financial method, which allows synergies in the design of the system by the financial management and the management of the information technology department and the creation of a common information space.

Keywords Investment activities · Effectiveness · Digital technologies · Digitization

JEL Codes M20 · M41

1 Introduction

Investment activity is a key factor in increasing the efficiency of not only organizations and institutions, but also individual countries. However, the situation with the development of investment financing is aggravated by the current economic, political and epidemiological situation in the world, when there is a lack of access to the financial and technological markets of developed countries in America and Europe. It's necessary to evaluate the results of such an impact, but the methodology for such an assessment isn't sufficiently developed.

In the global economy, it's also important to improve the use of unused or underutilized assets, and the development of a digital economy, which is developing everywhere, leaves its mark on the formation of investment projects and assessment of their effectiveness. The level of development of engineering and technology is becoming a factor in economic growth; it has a significant impact on the socio-economic development of society and the investment activity of business at the international and national levels. The digital transformation of the economies of all countries necessitates the creation of an international investment policy to create a global business infrastructure, develop digital techniques and technologies, and stimulate the participants of the digital market.

In addition to the influence of global factors, an important question arises about the choice by investors of effective investment projects and their further implementation in the context of the digital market economy. In addition, the market is usually focused on the implementation of investment projects for economically viable investors. The methodology for selecting projects is diverse, but doesn't reflect the specifics of the current business environment in the digital environment.

The problem of optimizing investment projects in the digital economy is also gaining key importance and plays a paramount role. The importance of adjusting the current methodology for accounting for investment costs in the digitalization of the economy is also increasing [1]. The dominant position is traditionally held by a

preliminary assessment because it's carried out at the stage of preparing an investment project, which means that it helps to make optimal and informed management decisions. However, organizations often face the problem of competing investment projects and the presence of several alternatives, subject to only one choice. In such a situation, the issue of selecting the most economically attractive project arises sharply, and for this it's necessary to compare alternatives for a number of significant parameters, which are specific to the digital development of the economy. Based on this, there is a need to consider various methods of analysis of investment activity in relation to digitalization processes. The application of a scientific approach helps to most rationally select and implement an investment project in the context of the development of the digital economy.

2 Methodology

For managing the investment activities, it is necessary to obtain the correct information and ensure the process of decision making. For creation of such information, legislative norms should be oriented at the needs of information provision of government and commercial organizations and other users.

For the purpose of optimization of accounting of investment activities, it is offered to distinguish the innovative activities in the system of investment activities of each subject of economy and within the financial and managerial accounting. This allows obtaining detailed information on the consumed resources and results. Therefore, investment activities contain a lot of components of the production and economic activities of companies, including the innovative activities, which are aimed at implementing the digital information systems.

Accounting of expenditures is to be modified in the following way:

1. Accounting should be conducted by the target principle.

This means that any investment activities in the digital information systems cannot be adopted if there are no clear goals and target results from these activities. Such principle is used in International Accounting Standards 38 "Intangible assets", and this norm should be adapted to the Russian law [2–4].

As the goal does not have quantitative characteristics for financial and managerial accounting, it is necessary to form such indicator and determine whether the goal of the project implementation is achieved. Therefore, it is necessary to adopt the target principle for the cycle of implementing the "expenditures-results" project, which will simplify the procedure of expenditures control, and determine the cost of the obtained assets.

2. Each investment project should be separate, which will make it unique.

A special methodology for evaluating the analysis of investment projects and grouping the information system by functions and purpose of investments involves the development and implementation of special forms of internal reporting.

Currently, in the era of a market economy, the main factors for decision-making are flexibility, innovation and speed. These circumstances, together with the calculated costs and quality control of work, are used by companies in the context of the digitalization of the economy in order to evaluate the success of their outsourced projects. Compliance with these factors allows companies to be competitive. In the modern world, the effectiveness of information technology is one of the main problems that constantly arise in front of Russian organizations.

In the conditions of the introduction of the digital economy, the impact mechanisms of digital information technology have changed. Initially, local applications with a limited scope were used. Currently, with the development of engineering and technology, information technology is embedded in most economic processes of an organization. They act as a link not only with organizational units in the company, but also outside of it. An example is an ERP system that allows you to manage company resources.

Some authors argue that a digital information system doesn't benefit the company [5]. Based on the analysis of cause and effect relationships, we have ascertained that digital information technologies have a significant positive impact on the performance of companies- there is an increase in revenue due to timely management decisions. At the same time, the introduction of high-quality digital technologies is quite expensive, significant investment is required, and as a result, the formation of investment projects and analysis of their effectiveness.

N Melville, K Kraemer, V Gurbaxani developed the structure of the mechanism of the impact of the digital economy on the financial stability of companies, which consists of two stages:

- The first stage is an increase in the efficiency of operational indicators;
- The second stage is operational indicators affect indicators that characterize the effectiveness of the company, such as: financial result or margin;
- The third stage is the deglaciation of the combination of operational and final indicators is carried out, which significantly changes the economic climate of the company and the digital information system [6].

Sekerina A. B. emphasizes in studies of the effectiveness of digital information systems that such an income component as "intangible" is of particular interest. At the same time, the scientist rightly asserts that this type of income provides a significant part of the profit and is a tool that stimulates the increasing in the competitive advantages of any company [7].

3 Results

At present—in the time of domination of the market economy—the main factors of decision making are flexibility, novelty, and speed. These circumstances, together with estimate expenditures and quality control, are used by companies in the conditions of economy digitization, for evaluating successfulness of their projects, which

are performed by outsource. Observing these factors allows companies to be competitive. In the modern world, effectiveness of information technologies is one of the main problems that Russian companies constantly face.

The vector of investment activity is aimed at growth of companies' competitiveness and at development of the country's economy on the whole. The Decree of the Government of the Russian Federation "Regarding the adoption of the Program of support for investment projects that are implemented on the territory of the Russian Federation based on project financing" regulates the investment projects that are implemented in Russia. This decree establishes the goal of Russian companies' entering a higher level of deglaciation of development, evaluation, and implementation of investment projects. An effective method of achieving the set goal is usage of the results of modern IT in the process of investment activities (Decree of the Government of the RF 2018).

The issue of information support for managing an investment project based on the modern information technologies comes to the foreground. Companies could use different forms and types of investments. Capital investments are real long-term investments (construction of objects, reconstruction/modernization of production, purchase of real property/land plot, R&D). The term of realization of such projects constitutes 1–5 years. Financial investments include securities that are purchases at the stock exchange, purchase of registered capital of other organizations, and crediting of other companies. The term of profit return—more than one year.

Portfolio investments do not bring large profit, but they are reliable (bank deposit). For all results to be obvious in a company, we recommend opening an additional sub-account, which reflects each separate article of revenues. If tax and financial accounting are conducted simultaneously, there could be differences in values in accounts. For example, non-refundable shares or obligations are accrued by the average market price, but the cost of these securities in tax accounting will equal zero.

Urgency and inevitability of this task became the reason of developing certain methods of analyzing the investment activities and evaluating the emerging possible problems. The methodology of analysis of effectiveness of investments for most companies should be effective and efficiency, being a system of quantitative and qualitative indicators, which could determine the connection between the processes and tasks of the investment activities and evaluate the company's strategic development.

The totality of methodologies of analysis and evaluation of innovative projects' effectiveness is grouped in the following way:

- financial methodologies;
- probability methodologies;
- qualitative heuristic methodologies.

As a result of analysis of investment projects' effectiveness, we determined that the financial method has a range of advantages:

– criteria of evaluation;
– theoretical basis;

– internal revenue norm;
– net current value.

Financial methods allow financial director to create a system and a "common speech" with the management of the information & technical department.

Application of financial methodologies brings companies a certain economic effect: calculation of work efficiency of sales managers and customer managers, improvement of the process of document turnover, and improvement of solutions of personnel tasks.

The process of implementation of progressive methodology of analysis and evaluation in a company envisages large expenditures for purchasing modern software and teaching employees. There are situations when increase of quality of products leads to increase of services and products' cost—especially in the case of usage of the modern information systems and technologies, which often is the reason of refusal from their implementation.

In the modern market conditions (which are changing very quickly), it is difficult to use the financial and probability methods with high precision. For the purpose of increasing the effectiveness of the investment activities, we suggest using the heuristic methods of analysis, which allow for qualitative characterization of each investment project. The basis of heuristic methods is experience and intuition of company's specialist and their decisions.

The advantage of heuristic methods is using them as the basis for supplementing quantitative indicators with qualitative ones. As a result of application of the offered method, there's an opportunity to select the most correct parameters for the investment project and its technologies, as well as to find the dependence on the purpose and specific features of each project.

Usage of the qualitative methodologies has a significant advantage—reorganization of production area, project, or company, introduction of complex measures, and change of the type of the activities are subject to the strategic plan of development. However, this does not stimulate achievement of the goal of obtaining quick financial profit. The drawback of such methodologies is that selection of the system of indicators of the project's effectiveness is subjective. If the company has skilled specialists in the sphere of implementation of innovative projects, probability of successful implementation is guaranteed.

We have also determined that most large companies use internal documents, which are developed by the company itself, for analysis and evaluation of the investment projects' effectiveness. Certain methodologies of analysis are adopted by public authorities. However, application of such internal methodologies is not always effective, as there are certain issues that negatively influence the correctness of investment project's evaluation: low qualification of personnel, errors of the methodology, and impossibility to connect the quantitative and qualitative indicators to the investment project's specific features.

The result of this research is preparation of the main requirements to the existing methodologies of analysis and evaluation of investment activities' effectiveness in the conditions of the digital economy:

– common interpretation of the methodology for the national economy spheres and for investment projects at the stage of development and implementation;
– timely and correct information for determining the quantitative and qualitative indicators;
– usage of a constructive motive of the methodology of analysis and evaluation = effectiveness investment project.

The developed requirements are correlated with the method of measuring the value of property, the core of which is the method of comparing the performance parameters of one company in a certain industry with another. The application of the developed unified requirements will enable companies to reliably evaluate the effectiveness of each investment project.

In the course of the study, it was found that the companies in the deglaciation of the assessment and analysis of the effectiveness of the investment project disrupt the comparison method, resort to unlawful comparisons, therefore, from our point of view, the method for implementing the project effectiveness assessment should be comparative:

– for effective process of implementation of technologies in the company, it is expedient to compare them with the analogs that were used earlier;
– it is necessary to compare the indicators of similar companies by sectorial belonging and similarity functions.

The main drawback of using the above methods is that each company independently develops a detailed system of indicators, based on which analysis of the investment activities' effectiveness is performed. The developed methodology is used by all departments of the company.

Selection of the indicators of effectiveness is largely subjective, which is a negative factor—for company's employees do not always have large work experience on implementation and participation in such projects.

We offer the following stages for calculation of revenues, expenditures, and indicators of investment activities' economic effectiveness in the company:

- 1st stage—formation of a strategic goal; as a result, a portfolio of projects is formed—which will influence the indicators of effectiveness.
- 2nd stage—evaluation of investments' effectiveness—determining the project's cost.
- 3rd stage—evaluation of the risk of the project's implementation.

Experts and large companies have developed their own sets of recommendations for determining revenues from implementation and calculation of the cost of expenditures that could be used by other companies. We have analyzed the companies' arguments for discussing the approaches to a set of parameters. It has been proved that in order to receive correct data it is necessary to observe a certain sequence of calculation and evaluation of risk.

The leading economists think that it is impossible to precisely evaluate the advantages from implementation of an innovative project. However, the sphere of stick

market activities has a rather effective evaluation, which allows for growth of shares in the profile companies [8].

In order to ensure a high degree of accuracy in estimating the project budget, we recommended using the programs that we have grouped depending on the size of the organization into three components:

1. For large companies, the use of large integrated packages of foreign developers

The first group is class MRP II/ERP. Such programs are focused on the management process in large companies with a branched structure, the range of goods and services offered, based on a process understanding of doing business (dividing the organization's lines of business into business processes).

2. The second group is the middle-class programs of domestic developers (Galaxy, Sail), which is developed on the basis of foreign, but mainly at affordable prices, taking into account the Russian specifics of accounting and reporting. Of course, such programs haven't reached the full implementation of MRP II/ERP technologies yet.
3. The third is local packages or programs of domestic developers aimed at automating accounting and management accounting (including personnel management, warehouse management and payroll). For example, "1C: Enterprise" refers to such a program, which adequately allows budgeting functions to be implemented.

For formation of the base of typical investment projects and their further usage, it is convenient to use the information financial accounting of capital investments, which implements the following: determining the totality of expenditures, formed as a result of creating a fixed assets object and conducting its reconstruction or revenues from other sources.

According to the chart of accounts, investment investments are reflected in investment objects on accounts 01 "Fixed assets", 08 "Investments in non-current assets", 10 "Materials", and 58 "Financial investments".

Organizations require more summary information for investment analysis, because of it, it's proposed to group the costs of all investments in a free account 06 "Investment activity expenses" in financial accounting. The debit of this account can reflect the costs of the investment project, the loan- business operations to write off costs. The balances are recorded under the item "Non-current assets" of the balance sheet and characterize the incomplete costs of investment projects (Order of the Ministry of Finance of the Russian Federation of October 31, 2000 N 94n, 2000).

In order to group the information system by functions and purpose of investments and to summarize the characteristics of private indicators in order to determine the change with the greatest reliability (under the influence of the selected application solution), an analytically detailed internal form of management reporting is developed—"Report on investment activity costs". The report is detailed according to the articles (functions and investments) for the reporting and planned data for a number of years; compiled on the basis of data from the reporting period of synthetic and analytical accounting, which can be directly transferred to the reporting form.

Detailing is carried out on the basis of first-order subaccounts (function articles), second-order sub-accounts—project implementation costs, third-order (investment items) [9–16].

4 Conclusions

As a result of studying the methodologies of analysis and evaluation of the investment activities within digital information systems and the modern methods of evaluating the usage of digital information resources, we have found out that, together with the classical methods of analysis and evaluation, it is expedient to use heuristic methods. It has been proved that imperceptible revenues are deferred revenues – which are usual revenues and provide large economic effect.

Promptly identify changes and carry out a comprehensive analysis of the effectiveness of investments in automated information systems allows the proposed form of internal reporting. Using the proposed reporting form, synthetic details (account 06 "Expenses for investment activities") and analytical accounting will make it possible to form an analytical and methodological basis for the analysis of investment activity in the context of digitalization.
