Socio-economic Systems: Paradigms for the Future

Springer

Studies in Systems, Decision and Control

Volume 314

Series Editor

Janusz Kacprzyk, Systems Research Institute, Polish Academy of Sciences, Warsaw, Poland

The series "Studies in Systems, Decision and Control" (SSDC) covers both new developments and advances, as well as the state of the art, in the various areas of broadly perceived systems, decision making and control–quickly, up to date and with a high quality. The intent is to cover the theory, applications, and perspectives on the state of the art and future developments relevant to systems, decision making, control, complex processes and related areas, as embedded in the fields of engineering, computer science, physics, economics, social and life sciences, as well as the paradigms and methodologies behind them. The series contains monographs, textbooks, lecture notes and edited volumes in systems, decision making and control spanning the areas of Cyber-Physical Systems, Autonomous Systems, Sensor Networks, Control Systems, Energy Systems, Automotive Systems, Biological Systems, Vehicular Networking and Connected Vehicles, Aerospace Systems, Automation, Manufacturing, Smart Grids, Nonlinear Systems, Power Systems, Robotics, Social Systems, Economic Systems and other. Of particular value to both the contributors and the readership are the short publication timeframe and the world-wide distribution and exposure which enable both a wide and rapid dissemination of research output.

Indexed by SCOPUS, DBLP, WTI Frankfurt eG, zbMATH, SCImago.

All books published in the series are submitted for consideration in Web of Science.

About This Book

This book is reflective of a science-based vision of the future development paradigm of economic and social systems. It deals with the digitization as the technological basis for the future development of economic and social systems and presents a review of groundbreaking technologies and prospects for their application. The specific character of the industry and prospects for the application of digital technologies in business are analyzed. A rationale is provided for future prospects for the sustainable development of economic and social systems in a digital economy. The authors determine the process of the formation and development of the information-oriented society, social and educational aspects of the digitization, as well as the institutional framework of the digital future of social and economic systems.

The book combines the best works following the results of the 12th International Research-to-Practice Conference "Artificial Intelligence: Anthropogenic Nature vs. Social Origin" that was held by the Institute of Scientific Communications (ISC) in cooperation with the Siberian Federal University and the Krasnoyarsk Regional Fund of support of scientific and scientific–technical activities on 5–7 December 2019, in Krasnoyarsk, Russia, as well as following the results of the 3rd International Research-to-Practice Conference "Economic and Social Systems: Paradigms for the Future" that was held by the ISC in cooperation with the Pyatigorsk State University on 5–6 February 2020.

The target audience of the book consists of representatives of the academic community concerned with the future prospects for the development of economic and social systems, as well as economic agents engaged in the digitization of business processes, and representatives of public agencies regulating the development of business systems for their progressivity, sustainability and competitiveness.

Contents

Digitization as the Technological Basis for the Future Development of Economic and Social Systems: A Review of Groundbreaking Technologies and Prospects of Their Application

Blockchain Technologies as a Reflection of Modern Reality: Diversity of Opportunities Versus Security Risks 3
Evgeniya K. Karpunina, Alexander M. Mikhailov, Natalya A. Bondareva, Olga A. Lyubimenko, and Elena V. Fedotova

Formation of a Justified Strategy of Education in the Sphere of Information Security in the Digital Economy 15
Gevorg I. Margarov, Elena A. Mitrofanova, and Lidia V. Anikeeva

The Influence of Digital Technologies' Development on Financing of Small Companies and Startups 23
Ekaterina A. Panova, Anastasia V. Kozhanova, and Arsen A. Tilov

Parametric Architecture and Artificial Intelligence as a Way of Modeling Three-Dimensional Environment 33
Daria G. Sohatskaya

Cloud Technologies in Banking 41
Elena P. Shatalova and Rasul M. Huseynov

The Power of Modern Digital Technologies for the Specialist Training in Artificial Intelligence 49
Zhanna S. Afanasyeva and Alexander D. Afanasyev

The Effectiveness of the Artificial Intelligence Development as a Factor in the Nonlinear Development of Social Systems 55
Alexander A. Berzan, Alexey V. Gubin, Alla V. Pavlova, Stanislav N. Vasilev, and Tatyana V. Skudalova

From Artificial Intelligence to Dissipative Sociotechnical Rationality: Cyberphysical and Sociocultural Matrices of the Digital Age 65
Sergey V. Leshchev

State Regulation of Blockchain Technology in the Sphere of Payments and Financial Services 73
Vera D. Nikiforova and Alexander A. Nikiforov

Ontology of Artificial Intelligence: On the Question of the Dehumanization of Social Regulators 81
Anna V. Popova, Irina V. Balashkina, Pavel V. Nikitin, and Galina A. Prokopovich

The System of Law and Artificial Intelligence in Modern Russia: Goals and Instruments of Digital Modernization 89
Anna V. Popova, Svetlana S. Gorokhova, Marianna G. Abramova, and Irina V. Balashkina

The Application of Artificial Intelligence for the Identification of Relevant Forensic Information Among Video Surveillance System Data 97
Ily'a O. Prichko and Aleksandr D. Afanasyev

Conceptual Approaches to Formation of Machine Building Product Development Systems 107
Ekaterina P. Garina, Elena V. Romanovskaya, Natalia S. Andryashina, Victor P. Kuznetsov, and Sergey D. Tsymbalov

Artificial Intelligence Instruments as the Basis for the Development of the Machine-Building Enterprises Export Potential 117
Galina Ya. Belyakova, Sergey A. Belyakov, Darya A. Fokina, and Anastasiya S. Shpak

Digital Technologies: Artificial Intelligence and Big Data in the Digitalization of the Russian Economy at the Present Stage 125
Olga A. Burova and Ekaterina A. Dolgikh

The Ratio of Staff and Artificial Intelligence in Modern Entrepreneurship: The Specifics of Small and Medium-Sized Businesses 137
Zhanna V. Gornostaeva

Secrets of the Empathy of Artificial Intelligence and Digital Economy. Philosophical and Cultural Aspects 145
Valeriy D. Didenko, Sergey G. Afanasiev, and Nikita A. Shcherbakov

Development of Urban Infrastructure Through the Introduction of Digital Technology 159
Ekaterina Yu. Kamchatova, Vladislav A. Chashchin, and Zhao Dong

New Technologies of State Supervision Over Labor in the Context of Economic Digitalization 169
Sergey P. Kosarin, Pavel V. Tereliansky, and Svetlana E. Titor

Historical Science and the Digitalization 181
Sergey P. Kostrikov, Alexandr A. Iliyuhov, and Elena V. Kryukova

Assessing the Capacity of Structural Segments of the Artificial Intelligence Market 191
Boris E. Tokarev, Tatyana A. Beregovskaya, and Roman P. Tokarev

Cross-Cutting Digital Technologies in the Management of the Competitiveness of High Technology Products 203
Nataliya G. Shalamova, Lidia S. Zelentsova, and Yulia V. Vorontsova

Robotization in the Economy 215
Alexey V. Zaitsev, Marina V. Bukhtoyarova, Snezhana V. Atoyan, and Natalia V. Mokrova

Artificial Intelligence Versus Human Intelligence in Socio-Cultural Measurement 227
Olga F. Morozova, Elena A. Nozdrenko, and Irina A. Panteleeva

On the Issue of Legal Support of Public Administration in the Context of Digital Transformation 241
Leonid L. Grishchenko, Yuliya L. Korabelnikova, and Oleg N. Dyadkin

Alternative Models of Economic Actors' Behavior and Interactions Under the Digital Transformation 249
Elena V. Kulyasova, Olga T. Shipkova, and Nikolay S. Kulyasov

Impact of Digital Technologies on Management Economics of Russian Companies 259
Irina B. Rodina

Project Management Transformation in the Digital Economy 269
Svetlana M. Sycheva, Tatyana F. Chernova, and Yuliya A. Evdokimova

Modern Approaches to Digitalization of the Company's Financial Task 279
Anatoliy B. Yaroschuk, Anatoliy Grekov, and Makhmud-Khussein Orusbiev

Creating and Measuring Company Value in the Digital Economy 287
Anna L. Denisova and Alexander N. Lopatnikov

Information Analytical Support of Analysis of Digital Economy Development 299
Marina D. Khabib, Marina Y. Teplyakova, and Aigul K. Bekkhozhaeva

Improving the Level of Digital Maturity of the Company (Based on Example of Reckitt Benckiser Group PLC) 309
Elena V. Kuptsova, Valeriy V. Maslennikov, and Irina A. Kalinina

Digital Technology for Vehicle Safety 323
Andrey G. Lipatov, Olga A. Tettsoeva, and Mohamed Conde

The Impact of "Smart Technology" on the Evolution of Ideas About the Subject Matter of Theft 333
Lyubov V. Lobanova, Larisa N. Larionova, and Alexey P. Rozhnov

The Application of Artificial Intelligence Technologies in Telecommunications 341
Sergey S. Golubev, Aleksandr I. Ivanus, Dina A. Aybosynova, and Viktor A. Chinaev

Economic Digitalization: Contradictions and Prospects 353
Andrey E. Sychev, Elena V. Zaytseva, and Pavel S. Tolkachyov

Digital Economy Development as an Important Factor for the Country's Economic Growth 361
Shakizada U. Niyazbekova, Luiza P. Moldashbayeva, Bakhytzhamal A. Zhumatayeva, Tatiana M. Mezentseva, and Larisa V. Shirshova

Industry Specifics and Prospects for Business Application of Digital Technologies

Using the Digitalization Experience of Small Enterprises of the Tourism and Hospitality Sector in Germany for Development of the Tourism Infrastructure in Russia 369
Alexey D. Chudnovskiy, Olga R. Tsabolova, and Marina A. Zhukova

Systemic Analysis of the Consequences of the Financial Market Digitization 377
Ksenia V. Ekimova, Nikolay V. Kuznetsov, and Olga I. Larina

Digital Technologies in the Hotel Industry: New Prospects for Sustainable Development 387
Valentina A. Kolobkova, Aleksey A. Romanov, and Elena A. Frolova

Assessing the Efficiency of the Digitization Process of the Russian Transportation Industry 395
Inna S. Prokhorova

Digitization in the Activities of Social Workers 409
Pavel V. Tereliansky, Nina A. Chernikova, Anna S. Shubina, and Elisaveta V. Terelianskaya

Innovations in the Retail Payment Market of Russia 421
Olga M. Korobeynikova, Dmitry A. Korobeynikov, Larisa V. Popova, Marina V. Glazova, and Ekaterina V. Kuzmina

Availability of Digital Financial Services: Problems and Solutions 431
Olga M. Korobeynikova, Dmitry A. Korobeynikov, Tatyana G. Agievich, Oksana A. Minaeva, and Svetlana J. Shaldokhina

Distributed Registries for Credit Cooperation: The Need and Opportunities 441
Olga M. Korobeynikova, Dmitry A. Korobeynikov, Mariya I. Kuzmina, Aleksandr V. Malofeev, and Svetlana A. Shevchenko

Digital Marketing and Sales Technologies: Dealership Marketing Management 451
Victor Ya. Konks, Evgeniy V. Krasnov, and Ekaterina V. Sumarokova

The Product Development System Category: Components and Modeling Approaches 465
Ekaterina P. Garina, Elena V. Romanovskaya, Natalia S. Andryashina, Yaroslav S. Potashnik, and Alexander P. Garin

On the Prospects of Digital Transformation of the Field of Sports 473
Andrey A. Dashkov, Maria N. Belousova, and Vladislav Yu. Pokazanev

Digital Monitoring for the Effectiveness of Financing Industrial Clusters in the Russian Federation 483
Aleksandr V. Voyko, Daria V. Voyko, and Olga D. Gaisha

Optimisation of Material Flows in the Concept Urban Mining Based on the Use of Long-Term Storage Depot 491
Svetlana B. Globa, Mikhail Ashkerov, Viktoria Arnold, and Viktoria V. Berezovaya

Tools to Smooth Regional Differentiation in the Digital Economy Formation Process 499
Zhanna A. Zakharova, Pavel N. Zakharov, and Andrey A. Cherkashin

Estimating Scientific and Technological Competitive Advantages: Study of Foreign Approaches, Type Classification of Business Entities and Influencing Factors 511
Evgeniya L. Moreva, Lyudmila V. Obolenskaya, and Antonina V. Sharkova

Recursion of the Temporal Paradigm of the Digital Economy Accounting 521
Roman S. Blizkiy, Valentin E. Malinenko, and Yulia S. Lebedinskaya

Management of Scientific and Technological Competitive Advantages in the National Industry 531
Olesya I. Dontsova, Niyaz M. Abdikeev, Yuriy S. Bogachev, and Segey A. Tolkachev

Attitude of the Russian Population towards the Processes of Digitalization of the Economy and Provision of Public Services 541
Elena Z. Imaeva, Julia V. Kostikova, and Natalia A. Sukhareva

Digitization of the Process of Administrative-Legal Declaration of Compliance with Mandatory Requirements by Supervised Entities as Part of an Automated Risk Management System 551
Anatoliy V. Zubach, Gleb N. Vasilenko, and Elena E. Tomilina

Digitalization and Application of Telemedicine Technologies in Healthcare of the Russian Federation: Economic and Legal Aspects 555
Farit N. Kadyrov, Abdula M. Chililov, Irina V. Shutikhina, Bagavdin G. Akhmedov, and Valery V. Antonov

Digital Socialization Agents in Adolescence 569
Sergey L. Kandybovich, Tatyana V. Razina, Aleksandr S. Solodukho, and Galina A. Fofanova

Application of Digital Technologies in Public Finance 577
Nadezhda S. Matveeva, Julia A. Lebedeva, and Olga A. Petrina

Digital Platforms as a Business Engine in Smart Space 587
Valentina V. Poliakova, Sona L. Sumbatyan, and Ester A. Hakobyan

Evaluation of the Effectiveness of the Implementation of Digital Public Procurement Systems: European Experience 595
Olga M. Pisareva and Svetlana A. Suyazova

Digitalization as a Driver of the Banking Sector 607
Elena B. Starodubtseva, Marina V. Grachyova, and Marina B. Trachenko

Legal Basis for Digital Transformation of State Control (Supervision) in the Labor Field 615
Svetlana E. Titor, Pavel V. Terelianskiy, and Sergey P. Kosarin

GR Management as an Innovative Model of Interaction Between Business Entities and Public Authorities in the Context of Digital Transformation 625
Iakow I. Kayl, Veronica S. Epinina, Roman M. Lamzin, Elena V. Zudina, and Julia M. Azmina

Transformation of Russian Banks Business Models in the Conditions of the Digital Economy Development 637
Tatyana Yu. Mazurina, Elizaveta I. Shamanina, and Klavdiya L. Neopulo

Use of Digital Technologies in Diagnostics of Functional Condition of the Russian National Basketball Team 3 × 3 Players 647
Raisa I. Andrianova and Marina V. Lenshina

Digital Scouting Technologies in Game Sports 655
Raisa I. Andrianova and Dmitry V. Fedoseev

Digital Transformation of Government Procurement on the Level of State Governance 663
Shakizada U. Niyazbekova, Roza Zh. Kurmankulova, Svetlana P. Anzorova, Makka G. Goigova, and Zeinegul K. Yessymkhanova

Oil and Gas Investment Opportunities for Companies in Modern Conditions 669
Shakizada U. Niyazbekova, Olga S. Ivanova, Buldyryk Suleimenova, Saltanat K. Yerzhanova, and Rysty K. Berstembayeva

Problems of Digitalization of Fiscal Authority in Passenger Traffic . . . 677
Anatoliy V. Zubach, Tatyana A. Lakhtina, and Lyubov S. Komovkina

Uniform Approximations to Solutions of Singularly Perturbed Systems of Differential Equations with the Eigenvalues Which Have No Zero in the Region Under Consideration 683
Saly K. Karimov and Guljamal M. Anarbaeva

Digital Transformation of the Financial Services Market in Russia . . . 689

Blockchain Technologies as a Reflection of Modern Reality: Diversity of Opportunities Versus Security Risks

Evgeniya K. Karpunina, Alexander M. Mikhailov, Natalya A. Bondareva, Olga A. Lyubimenko, and Elena V. Fedotova

Abstract Digital technologies determine the dynamics of social and economic development of modern states. The emergence of blockchain technologies has created conditions, on the one hand, for the optimization of business processes in various sectors of the national economy, and, on the other hand, for the emergence of new threats to security, primarily information and economic properties, which can call into question the well-being of society and the sustainability of the state. The purpose of the study: to analyze the content characteristics of the blockchain technology, the trends of its implementation in various sectors of the economy and limitations, as well as to justify the blockchain technology as a promising tool for the development of the digital economy and overcoming the factors of global instability. The content characteristics of the blockchain technology are investigated, and their advantages for use in various sectors of the economy are determined. The classification of blockchain applications used in business is given depending on the mechanism of their implementation. The industry structure of the blockchain technology market is analyzed. The countries where blockchain is most actively developing are highlighted-the USA, China, and the UK. The degree of implementation of blockchain technologies in various sectors of the economy is analyzed, as well as the economic benefits of their

1 Introduction

Blockchain, introduced to the world in 2008, like any new technology, has gone through many stages of its development over the decade: from complete rejection to rapid growth and mass implementation in real technological processes in various industries. The prospects and benefits of using this technology are discussed at the level of households and individuals, large corporations and financial communities, and at the state level.

Giants of the IT industry and financial sector, such as IBM and Microsoft, Oracle, Visa and Master Card have already started to develop blockchain products and services, in order to ensure a high level of trust and confidence. Indeed, numerous studies reveal the absolute advantages of new blockchain technologies aimed at improving the performance of industrial systems and financial calculations, government databases, and digital identification systems.

However, experts still have serious concerns about the safety of this tool for modern society, its reliability and ability to become a priority tool for the development of the digital economy and maintaining its stability. Thus, the problem of correlation of opportunities and threats from the use of blockchain technology in various sectors of the economy and spheres of activity currently requires special research attention.

2 Methodology

2.1 Purpose of the Study

Analysis of the content characteristics and trends in the introduction of blockchain technology in various sectors of the economy, the study of restrictions and justification of blockchain as a promising tool for the development of the digital economy and overcoming the factors of global instability.

2.2 Research Methods

Information and descriptive methods; structural and functional methods; comparative method; dialectical method; analytical method; classification method; modeling method.

2.3 Theoretical Foundations of the Research

The blockchain was originally developed for the digital currency bitcoin. The theoretical basis for creating a new generation of electronic currency is described in the article Satoshi Nakamoto "Bitcoin: peer-to-peer electronic cash system" [9]. The features of blockchain technology are described in the works Dyba and Dingsoyr [4], Swan [13], Wang and Liu [15], Iansiti and Lakhani [7]. Practical aspects of applying the technology of the blockchain is described in the book of Tabernakulov and Kojfmann [14].

2.4 The Information Base of the Research

The information base of the research is presented by analytical reports and forecast materials of Spanish bank Santander, Chinese Academy of information and communication technologies (CAICT), IDC group, Bain & Company, World Economic Forum, World Bank, Santander, OECD.

2.5 Results

Let's look at the content characteristics of the concept of "blockchain". Blockchain is a continuously growing chain of blocks with records of all transactions, while copies of the database or part of it are simultaneously stored on multiple computers and synchronized according to the formal rules of building a chain of blocks. The information in the blocks is not encrypted and is available in clear form, but the absence of changes is verified cryptographically through hash chains, that is, it is an element of a digital signature. In fact, blockchain, as a chain of blocks, is similar to many traditional electronic payment systems and interbank networks like SWIFT and has differences in the methods of information transfer and management. The distinctive characteristics that make blockchain technology a popular system in various processes are presented in Table 1.

In addition, the blockchain technology has an advantage in the speed of transactions and their efficiency, due to the elimination of intermediaries and full automation of processes. It has the potential to significantly reduce costs by eliminating the need to verify the completeness and purity of the transaction, which leads to faster transactions and settlements. Additionally, the blockchain reduces the cost of infrastructure transactions. It is estimated that the introduction of blockchain in the

Table 1 Distinctive characteristics and advantages of blockchain technology (compiled by the authors)

Differences between blockchain technology and other technologies	Advantages of blockchain technology
Decentralization of information storage and processing processes	• All information recorded in it is stored by each network member in full • The blockchain exists as long as at least one of its nodes is functioning, and the load on each individual node is relatively small • There is no need to create geographically distributed networks with expensive data centers, centralized data storage and backup systems, and local access to data for each node of the network • Decentralization reduces the cost of traditional technologies, improves the security of data and processes, and facilitates the introduction of new products to the market
Provable data immutability	• Blockchain allows you to check the entire sequence of adding information at any time and exclude the possibility of making any changes to individual sections of the chain without its complete restructuring • Reduces fraud and improves the level of confidence in technology
Transparency of operations	• In single-level blockchains, all network participants have the same rights, they take all the information about the operations taking place in the blockchain for storage • All the contents of transactions in public blockchains are available for reading by any network participants, but access to changing other people's data is not possible without the corresponding private key • Blockchain offers absolute honesty and openness: everyone can see the entire history of operations of their counterparties and it is never erased • Reduces fraud and improves the level of confidence in technology

(continued)

Table 1 (continued)

Differences between blockchain technology and other technologies	Advantages of blockchain technology
Irrevocability of transactions	• In public blockchains, transactions are irrevocable, they cannot be returned to their original state after confirmation-inclusion in the block and the formation of subsequent blocks • In the blockchain, it is almost impossible to cancel a confirmed transaction, and the entire history of payments between counterparties is stored in open form, which eliminates the need for mutual reconciliation of payments • Reduces fraud and improves the level of confidence in the technology
The possibility of anonymisation of participants	• Addresses in the blockchain are unique identifiers consisting of an impersonal set of characters, the blockchain does not contain any information that allows you to uniquely link the wallet with its owner • All payments in the blockchain are saved forever • Reduces fraud and improves the level of confidence in technology
No need for trust	• Blockchain users do not know each other when making transactions, but decentralized payment processing eliminates the need for trust between transaction participants—if the transaction is correct and sent to the correct address, it will reach its destination • The recipient of the payment cannot take the money without fulfilling its obligations, due to the presence of a decentralized mediation mechanism • Reduces fraud and improves the level of confidence in technology
Maintaining the network by the participants themselves	• Blockchain users are the owners of their tokens and other information stored in the blockchain • Each blockchain is supported by a group of independent developers who do not receive direct payment for their work • Increases the level of confidence in the technology and reduces the cost of operating the technology management body
Security and the inability to limit the transactions of clients	• There is no single management center, meaning it is almost impossible to block transactions, implement any regulation, or freeze or confiscate funds • Increases the level of confidence in the technology and reduces the cost of operating the technology management body

(continued)

Table 1 (continued)

Differences between blockchain technology and other technologies	Advantages of blockchain technology
Automation and programmability	• Allows you to program pre-agreed conditions that are automatically fulfilled when a certain condition is met-smart contracts (for example, payment of bills on arrival of cargo) • Improves the security of many traditional technologies and reduces the risk of fraud

financial industry can reduce losses associated with fraud by 15–20 billion dollars a year [12].

The blockchain interface actively adapts to different application scenarios when providing various services and applications. Depending on the implementation mechanism and application goals, blockchain technology can be divided into three types of scenarios: first, the transfer of values, second, the receipt of data or documentation of data, and third, authorization management. The main classification of blockchain applications used in business depending on the implementation mechanism is given in Table 2.

IDC analysts believe that the market for blockchain technologies will grow by an average of 60.2% per year, and by 2023 will grow to 15.9 billion dollars, and in 2019, global sales of blockchain technologies will be at least 2.7 billion dollars, which is 80% more than in 2018 (Fig. 1) [8].

Analysts IDC in its report Worldwide Blockchain Spending Guide indicates that the largest volume of investment in 2019 in blockchain technology will be the US—the volume of investments of 1.1 billion dollars, the EU—investment of

Table 2 Classification of blockchain applications used in business, depending on the implementation mechanism (compiled by the authors) [3]

Type	Governance	Finance	Industry	Healthcare	Law	Copyright
Value transfer		Digital bill Account receivable Supply chain Finance	Energy deal	Health insurance		
Receipt	Electronic invoices Digital license Targeted poverty alleviation	Cash serial number Traceability Supply chain finance	Security Traceability	Electronic medical record Medicine trackability	Notary Digital Receipt Online arbitration	Copyright verification
Authorization management	Government data sharing	Credit investigation		Health data sharing		Copyright management

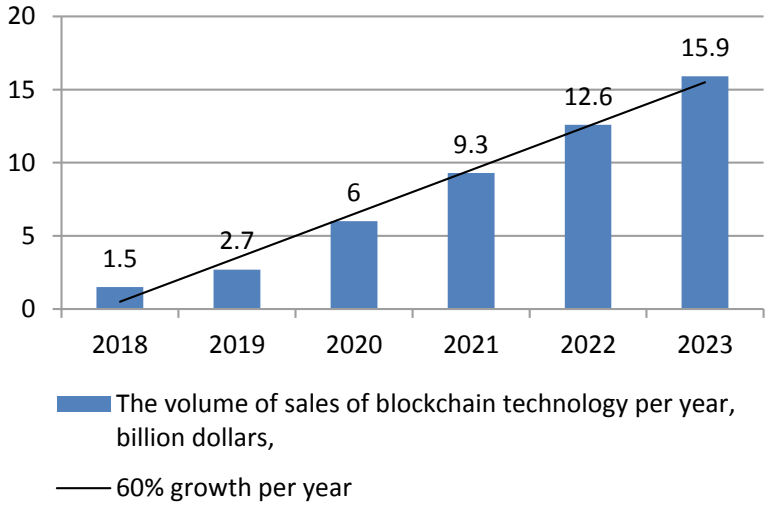

Fig. 1 Dynamics of growth of the blockchain technology market until 2023, billion dollars (compiled by the authors according to IDC forecast)

674 million dollars, China—319 million dollars. Japan and Canada with five-year CAGRs of 110% and 90%, respectively, will be the most dynamic in terms of growth in blockchain spending in the five-year period.

If you look at the structure of financing, the volume of ICO financing amounted to more than 18 billion dollars, which is significantly higher than the volume of traditional financing for the same period. The financial sector will be the leaders in terms of investment in the blockchain in 2019 among the industries—about 30%, due to the rapid introduction of this technology in the banking sector and insurance. Sectors with a continuous nature of production follow with 20% of the investment volume. At the same time, the cost of blockchain among enterprises of continuous production will grow fastest—by 68.8% annually. The discrete manufacturing industries, the professional services sector, retail and utilities will also grow faster than the market as a whole.

Blockchain technology will be a driver of growth in the e-Commerce segment. Thus, according to IBM forecasts, about two-thirds of banking operations will be carried out through this technology by the end of 2020. The Banking sector, the securities market, the investment services sector and the insurance market will invest more than $1.1 billion in blockchain technology. The industry with the mining and processing sector will invest about 653 million in the blockchain in 2019. The distribution and services sector, led by the retail and professional services industries, is about $642 million. The fastest growth in blockchain spending in the period 2018–2022 with a five-year CAGR of 77.6% is projected in the industry with the mining and processing sector. This is followed by the distribution and services sector with a CAGR of 77.1%. In 2019, the volume of investments in the blockchain sector of international settlements and trade Finance sector will amount to 453 million dollars

and 285 million dollars, respectively. If you look at the industry structure of demand for blockchain products, it should be noted that the greatest demand for blockchain is observed from the financial sector and the insurance market—almost half of all blockchain projects are launched in the financial sector (42%), and the least demand is from the public sector (13%).

Let's consider the features of the introduction of blockchain technology in various industries and the economic benefits of their use. The main advantage of blockchain in the financial market is the democratization of access to financial resources and services. This technology can offer customers "instant" payments, simplify payments in transnational payments and thus challenge the traditional strong monopolists in the financial market-large banks and insurance companies. Major players use this benefit and take active steps to implement blockchain in their calculations in order to prevent a decline in shares in financial markets. In addition, the blockchain creates an opportunity to liberalize financial transactions. This is important in the current regulatory environment of the financial market on the part of the Supervisory authorities, including due to the impossibility of limiting the operation of blockchain applications and imposing any restrictions.

The securities market and its accompanying depositories are also actively implementing blockchain technology. Thus, the blockchain is tested by the world's largest exchanges NASDAQ, NYSE and LSE, and others. The use of blockchain technology in the stock market allows you to reduce transaction costs and accelerate calculations in the market, reduce the number of intermediaries, which leads to lower commissions, operating costs and counterparty risks, increases market confidence. [2]. In addition to the private sector, blockchain projects also cover the public sector. For example, the report of the World Economic Forum indicates that more than 40 Central banks are exploring the possibility of implementing various blockchain scenarios at the state level, and the public sector already has 202 blockchain initiatives covering 45 countries [10]. The assessment of the impact of the new blockchain technology on various sectors of the world economy is presented in Table 3.

However, some IT specialists see in the action of the blockchain flywheel not only the multifaceted capabilities of the technology, but also hidden limitations and threats [5, 11]. For example, Harvard Kennedy school security technologist Bruce Schneier argues that there is no real economic value behind the success of the blockchain, it has an external limitation in terms of user roles and the consensus mechanism [17]. Experts of the International interbank system of information transfer and financial transactions SWIFT also point to the danger of unrealistic expectations regarding the hype around blockchain in the banking environment and the difficulty of achieving the potential benefits of blockchain technology [6]. CAICT experts point out that the blockchain technology is plagued by failures of the initial stage of implementation, and about 92% of them fail, and the average period of their implementation is 1.22 years [3].

Assessing the negative aspects of blockchain technologies, it should be noted that due to its immaturity, it can create new risks and difficulties for traditional processes. For example, technological, legal and regulatory risks, as well as problems of scalability, compatibility, operational security and cybersecurity, protection

Table 3 Assessment of the impact of the new blockchain technology on various sectors of the world economy (compiled by the authors)

The advantage of blockchain / Industries	Full traceability of any information s	impossibility of data forgery	Distributed nature of the technology	Smart contracts and automation	Increased speed and efficiency	Increased security	Transparency of transactions for all blockchain participants	New business products or services

of personal data, privacy should be attributed to such risks. The use of blockchain technology is transnational in nature, so it is necessary to take into account the risks and complexities of subsequent transnational disputes, as well as the problems of regressive mechanisms. We also note the problem of all new "breakthrough" technologies—the problem of insufficiency and incompleteness of the regulatory legal framework. In addition, there is a legal risk of supporting the process of using the blockchain, as well as the risk of difficulties and significant costs in the processes associated with the migration of existing IT platforms, operating mechanisms and institutional foundations of the financial market infrastructure to new blockchain platforms. Therefore, we can assume that the mass initial transition to blockchain technology will be in the financial market sectors that do not have previously implemented and tested IT platforms, for example, in the markets of trade finance and syndicated loans.

Blockchain technology is an IT system that works with a constant increase in load. In this regard, there is a risk of insufficient scalability, that is, the ability of blockchain platforms to cope with the increase in workload when adding new resources. This may limit the ability to increase transaction volume and processing speed. Blockchain may face the problem of integration or compatibility with current systems, which can lead to higher costs in traditional processes. There is a high probability of computer security risks, in which the software is not immune from technical vulnerabilities. Blockchain has good cryptographic protection, but this does not exclude attacks. Massive cyber attacks carried out by rogue groups pose a serious threat to critical infrastructure. At the same time, they hit the control systems of military forces, transport and energy management systems. According to experts of the World Economic Forum, one of the main risks of the modern economy is a possible regional or global economic instability, which can be caused by purely economic reasons, such as a sharp depreciation of one of the currencies, a default on the foreign exchange debt market, as well as possible military conflicts and cyber attacks [16]. So, according to analysts, the total damage from successful cyber attacks by 2022 will be 10 trillion dollars, and private sector companies in the next five years risk losing 5.2 trillion dollars, which is comparable to the combined size of the economies of France, Italy and Spain. Cyber attacks will lead to a nearly 3% decline in global private company revenues by 2023 [1]. These security risks spur a response in terms of increased spending on cybersecurity, which according to Gartner forecast amounted to 123 billion dollars in 2018 and will grow at least 10% per year and will amount to 170 billion dollars by 2022 [17]. Moreover, the growth of these costs for cybersecurity is also stimulated by the emergence of a large number of startups (4123 projects) in the field of cybersecurity, which have already attracted more than 120 billion dollars, starting in 2009, while studying the possibilities of blockchain in terms of protecting the digital economy and the cryptocurrency market [18].

Another weakness of the blockchain sphere is the lack of regulatory documentation and the lack of quality industry standards. The blockchain is immutable and distributed, so there is a high probability of problems with correcting incorrect or erroneous data-regression of transactions, which may be solved by conducting a separate transaction that will correct the error. The risk of lack of confidentiality

reduces trust in the technology of the blockchain. In many blockchains, all transactions are open and accessible to all network participants, although they may be encrypted. Another possible problem with blockchain technology is the right to be forgotten. In the way of the blockchain can be an obstacle in the form of rejection of the blockchain by many States and institutions. Often the barriers of new technology are based on excessive state control and the fight against excessive freedom of monetary circulation.

However, numerous risks become insignificant before the role of blockchain in the fight against economic problems and a positive assessment of its role in increasing the stability of the global digital economy. Thus, the current trend of economic security is aimed at tightening the role of state control both within countries and at the supranational level. This tightening is aimed at protecting the markets of specific countries and the interests of global players, as well as ensuring economic growth in individual countries. Many developed countries, which are caught up in the digital wave and mass automation, are currently facing problems of slowing economic growth at an average of 2.4% in 2018, which, in the actual absence of growth in the economies of developing countries, carries global risks. Blockchain technologies, in our opinion, can help the state to ensure confidence in existing economic processes, especially in case of possible global instability caused by both technological reasons and economic crises, limiting the role of the state in the excessive globalization of the world economy and reducing the regulation of the economy, trade wars and the growth of economic tension.

3 Conclusions/Recommendations

As a result of the study, the following results were obtained. It is proved that the blockchain technology is a promising tool for the development of the digital economy and overcoming the factors of instability due to the expanded possibilities of decentralization of information storage and processing, provable immutability of data, transparency of operations, irrevocability of transactions, the possibility of anonymization of participants, the lack of need for trust, maintenance of the network by the participants themselves, security and the impossibility of limiting customer operations, automation and programmability. The analysis of the dynamics of blockchain technology and the practice of its implementation, has allowed to draw a conclusion on the sectoral market structure blockchain technology: the greatest demand on the blockchain is coming from the financial sector and insurance market, and the lowest demand from the public sector. The impact of blockchain technology on the development of various sectors of the world economy is evaluated. The action of the blockchain flywheel is investigated based on the energy of understanding the value of the technology and its feasibility: the emergence of trust in the blockchain, acceleration due to its scalability, simplification and acceleration of implementation by sharing best practices, approval of the blockchain by the state and the development of a regulatory framework for its regulation. Hidden limitations and threats of

blockchain technology are systematized: substitution of real economic value, presence of external restrictions in terms of user roles and consensus mechanism, the possibility of creating new risks and difficulties for traditional processes.

Formation of a Justified Strategy of Education in the Sphere of Information Security in the Digital Economy

Gevorg I. Margarov, Elena A. Mitrofanova, and Lidia V. Anikeeva

Abstract Formation of a modern information space leads to emergence of serious risks and new threats for information security of person, government, and society on the whole—which leads to increased responsibility of each member of the society and its protection. Thus, the issues of training of specialists in the sphere of information security become very important. The purpose of this paper is to substantiate a strategy of education in the sphere of information security in the conditions of the digital economy. The research results include determining the target groups of the educational system in the sphere of information security, justifying the system of support for interested parties, forming a model of education in the sphere of information security, organizing training in the sphere of information security, and creating a system of informing the society on the issues of information security. The research proves the conclusion that formation of a justified strategy of education in the sphere of information security could reduce the influence of risk of cyber security and stimulate the acceleration of economic development and increase of the level of comfortable interaction in the information infrastructure.

1 Introduction

In the recent decades, innovative usage of the cyber space transformed the everyday activities of people, forming the modern information society, which is characterized by high level of development of IT and their wide application in almost all spheres of human activities. These achievements improved human life and created comfortable conditions of functioning of commercial, government, and public organizations [1]. In Russia and Armenia, the information sphere, which was proclaimed the top-priority direction of development of the country's economy, largely predetermines the state of political, economic, and defense aspects of national security.

The processes of digitization of economy and life of society lead to emergence of serious risks and formation of new threats for information security of person, government, and society on the whole [2]. Unsanctioned access, destruction or disclosure of information, and violation of the processes of its processing and transfer in the information systems deal large material and moral damage to all participants of the processes of information interaction [3]. Growing dependence of society on cyber space—as a critical component of infrastructure—predetermines the increased responsibility of each participant of society for their protection [4].

2 Methodology

As the problems of provision of information security become more complex and significant, they are the focus of attention of government and commercial structures. One of the most important directions of research and practical activities in the sphere of provision of information security is training of personnel in this sphere of activities [5].

Provision of information security at the national and international levels is based on vigilance regarding risks in cyber space and envisages presentation of training in the sphere of information security for all groups of population [6].

The following tasks should be solved in order to achieve this goal:

- determining the target groups of the educational system in the sphere of information security;
- substantiating the system of support for interested parties;
- forming a model of education in the sphere of information security;
- organizing training in the sphere of information security;
- creating a system of informing the society on the issues of information security.

3 Results

3.1 Target Groups of the Educational System in the Sphere of Information Security

The target audience of the educational system in the sphere of information security could be divided into three main groups [7]:

- pupils and students,
- specialists in information security,
- wide public.

It is obvious that the educational tasks for each target group are specific and could be described in the following way:

- expanding the circle of persons who are ready to enter the practical activities in the sphere of cyber security by means of increasing the interest to the subject sphere and training of specialists on information security.
- increasing public awareness of the risks of information security with provision of the main information for individual and organizations about protection in cyber space.

Generally speaking, requirements to education and the applied educational technologies for each target group should conform to the specific educational tasks and the level of their interaction and responsibility in cyber space. As interaction in cyber space at different levels and with different responsibility is expected, target groups and educational tasks could have certain repetitions.

3.2 Support for Interested Parties

Achieving high quality of education and solving the above educational tasks for each group are not possible without active support for interested parties, which are a wide circle of organizations, which receive real or indirect profit from successful educational activities [8]. In this context, the interested parties could include government, commercial, public, territorial and academic entities and organizations, professional associations, information associations, and individuals. Each of the three above tasks envisages the key selection of interested parties, the initiation and preservation of mutually profitable relations with which are among the main strategies of educational organizations that are decisive for the global initiative of provision of information security.

In view of the fact that interested parties have independent and free goals, tasks, and methods, which could be contradictory, one of the main methods of cooperation for an educational organization is achieving a compromise and consensus. For provision of correspondence to quickly changing realia of the sphere of information

security, educational programs and their content should be developed and regularly update in view of statistically generalized feedback from interested parties [8].

3.3 Models of Education in the Sphere of Information Security

Recently, due to active transition to the concept of Lifelong Learning, three main models of education have been recognized: formal, non-formal, and informal [9]. These models correlated with the educational practices in the sphere of information security. Comparison of these models with the above target groups and the corresponding educational tasks allows distinguishing three main models of education in the sphere of information security:

- organized training with assigning qualification according to the national framework of qualifications (formal education),
- advanced training and retraining of specialists (non-formal education),
- public dissemination of information (informal education).

These models of education should function in close contact with certain functional entities for provision of information security at the national level. Thus, the unified organizational management and technical support from higher educational establishments, which implement the government program of training of skilled specialists in the sphere of information security, is preferable.

In the modern society, risks in cyber space are caused by combination of two main conditions:

- large changes in technologies that predetermine the necessity for educational system to prevent the risks of information security;
- higher dependence on the information infrastructure, which creates more opportunities for cyber attacks.

As the landscape of the information infrastructure and the methods of access to information and its usage constantly change, it seems expedient to perform constant monitoring with frequent correction of approaches and content, for satisfying the current educational needs in the sphere of information security.

3.4 Organized Training in the Sphere of Information Security

In the course of dissemination of IT in all spheres of human activities, all educated people have to know how to work with IT and to know the basic security rules. Thus, it is recommended to add the corresponding lessons to high school programs and university programs for all specialties—primarily, for engineering specialties.

On the other hand, as the world becomes more connected to cyber space, protection of various information systems require more skilled specialists in the sphere of IT. Most of the modern organizations of private and public sector experience a lack of skilled specialists for evaluation, development, and implementation of solutions and strategies in the sphere of information security. At present, demand for such professionals grows quicker than offer from the corresponding educational establishments. The lack of information security specialists is also peculiar for specialized educational establishments, which leads to large deficit of such specialists in society. In order to fill this gap, it is necessary—together with the key interested parties—to implement a range of measures for stimulating early interest in cyber security. Besides, the corresponding structures of organization and management of education should consider the perspectives of expansion of the system of training in the sphere of information security.

During training of specialists with higher education in the sphere of information security, the main problems are as follows [10]:

- low level of pre-university training of future cyber security specialists, as the school course of informatics contains only mention of certain aspects of information protection,
- not meeting up the modern requirements of the qualification level of academic staff, due to absence of basic education and practical experience of work in the sphere of information security,
- material and technical basis does not conform to studies, as it does not contain the necessary special technical and software means of information protection, due to their high prices.

The main principles of provision of high quality of training of information security specialists are as follows [11]:

- active interaction with interested parties during development of the contents of the educational programs and execution of joint applied projects, as well as involvement of the leading specialists in the sphere of information security into active teaching activities;
- provision of the educational process's correspondence to the dynamic changes of the professional environment and synchronization with the labor market's needs;
- acquiring the practical skills of usage of protection means in the conditions of modern cyber threats;
- forming the conditions of the educational environment that form students' motivation for participation in the innovative activities.

The perspective ways of increasing the educational process's activities are various methodological solutions, which include the competence-based and innovative approaches.

3.5 Advanced Training and Retraining of Specialists

Training of information security specialists has been conducted for decades, but this sphere of activities is still underdeveloped, and a lot of its aspects are not fully determined. Effective rapid planning of human capital based on determining the needs of specialists with the corresponding set of professional competencies will allow solving the problem of lack of information security specialists. This will allow planning the specialists' training and determining the need for advanced training and retraining of specialists.

Being a relatively new sphere of professional activities, information security does not have a clear general description of responsibilities and required knowledge and skills. It is expedient—in the near future—to develop a sectorial framework of qualifications on information security, which would help creating programs of advanced training and retraining of specialists based on their current competencies. This framework should be comprehensive with coverage of all possible jobs, and also flexible and dynamic, envisaging regular update of the content based on feedback from the interested parties.

Despite the need for additional specialists on information security, there is no common methodology for determining the necessary number of specialists at specific jobs. Thus, it is necessary to develop a methodology of calculation and forecasting of the need for personnel according to the current sectorial framework of qualifications. Naturally, development of such methodology could be based on studying how organizations in various spheres of industry forecast the need for work force and how the unique problems of the information security sphere could influence forecasting.

Skilled specialists of information security should be provided with regular specialized advanced training, which will guarantee possession of knowledge, technical skills, resources, and trust to execution of their role. In the course of development of the need for specialists on information security, the updated sectorial framework of qualifications will help to plan advanced training and retraining of specialists and to formulate the requirements to formal training, aimed at satisfaction of the changing needs of the labor market.

3.6 Public Informing and Dissemination of Information

Most people in the modern society communicative with the information infrastructure for performing their official duties and satisfying personal needs on a daily basis. Thus, there is a need for systemic and targeted work on informing wide public on the risks in the information space and teaching the usage of resources and tools of security for reducing cyber risks.

In cooperation with interested parties, it is necessary to develop information materials and effective mechanisms of their delivery for a wide circle of consumers. Information materials should be created in various forms in view of the available

means and methods of public informing—special courses, thematic competitions, and extracurricular measures.

IT users, knowing about various available tools and resources of security, often do not understand how to select the necessary activities and tools or which confidentiality settings should be used for provision of security on Internet. It is necessary to inform wide public—in a popular form—about practical recommendations for effective usage of such tools and resources.

4 Conclusion

Training of information security specialists remains one of the foundations of sustainable development of the modern economy and society on the whole. Formation of a justified strategy of education in the sphere of information security, in view of all factors that influence the quality of specialists training, could reduce the influence of the risks of cyber security and stimulate acceleration of economic development and increase of the level of comfortable interaction in the information infrastructure.

The Influence of Digital Technologies' Development on Financing of Small Companies and Startups

Ekaterina A. Panova, Anastasia V. Kozhanova, and Arsen A. Tilov

Abstract Over the recent several years, the financial sector underwent substantial changes due to development of digital financial technologies, which stimulates the increase of the opportunities of access of small and medium-sized enterprises (hereinafter—SMEs) and startups to financial resources by means of appearance of P2P crediting, crowdfunding, and the tools of financing based on blockchain—in particular, ICO. In view of the dissemination speed of the technological progress achievements, these changes will continue and they cannot be ignored. This paper studies the influence of digital technologies development on the changes in the financial sources of SMEs and innovative startups. The purpose is to perform an empirical research of the influence of factors—primarily, digital—on the change of the volumes of SMEs alternative financing with the usage of a set of data from open information sources on financing of SMEs and startups in 17 countries. The research method is regression analysis. Its results show that the change of the volumes of ICO, number of Internet users, and volumes of venture financing has large influence on the changes of the volumes of SMEs alternative financing. The authors distinguish the main directions of the emerging technologies' stimulating the improvement of SMEs access to financing and complexities that arise during their application. The results of the performed research could be used for further study of the factors that influence the development of alternative financing of SMES and startups.

1 Introduction

The recent years of the global economy development have been peculiar for so called financial and technological revolution, which has been based on usage of digital technologies and the related transformation of the financial system on the whole and the banking sector in particular. It has been traditionally believed that banks are the main source of innovations in the financial sector—however, there is an opinion that the recent real innovation for final users was ATM in 1970 [5]. Half a century passed since then—and the time of a new revolution came. Fintech revolution, which is based on digitization, changed the banking sector and spawned a range of new financial services and products—bitcoin, P2P crediting, crowdfunding, mobile payments, and online insurance. Besides, banks created barriers for crediting small and medium-sized enterprises (SMEs), which led to development of an alternative financial market.

The experts of the SMEs credit market acknowledge the limitation of the traditional debt-based banking financing for satisfying various needs of SMEs, which they face during their life cycle [8]. The main problems that hinder bank crediting of SMEs are as follows:

- information asymmetry;
- high transaction costs and lack of own means and short-term assets;
- absence of public information or its low quality, including incompleteness of financial reports as compared to large companies;
- insignificant volume, limited credit history, and unclear business models, which complicate evaluation and monitoring of credit risks, as well as other structural barriers.

The financial crisis also reduced the trust of people to traditional banks, making them using new methods of investing with higher profitability more readily.

In particular, traditional debt financing is not good for innovative and quickly growing startups, which, according to E. Ries—an author of popular books about startups, develop in the conditions of uncertainty and increased risk of bankruptcy [10]. The statistics also confirm this.

According to the OECD [9], traditional banking financing continues growing (by 2–3% annually in developed countries and 5–6% annually in developing countries); the volumes of alternative sources, which finance innovative startups and SMEs, grow quicker.

The recent available data for 2017 show expansion of the tools of non-banking financing of SMEs, in particular the following:

- volumes of factoring, based on demand of international growing SMEs, in the OECD countries grew by 3.3% on average, showing similar growth rates as compared to previous years;

- lease and other secured instruments grew in 24 out of 34 studied countries by 6.2% on average with potential of replacement of banking crediting of SMEs;
- private crediting grew by 10% in the OECD countries, and by 27% in Europe (this tool is especially important for mature SMEs, which plan to change the owner, enter new markets, and/or expand their types of activities);
- venture investments grew in most countries, and the number of SMEs that use this tool constantly grows;
- financing with participation of business angels grew in Europe by 9%, in the USA—by 12.6%;
- such types of alternative online financing as crowdfunding and P2P crediting grew substantially in recent years—especially in countries where the share of these markets was small—in particular, China, following the USA and the UK, developed the largest market of alternative financing.

The observed development of alternative sources of SMEs financing is aimed mainly at satisfying the needs of new innovative companies, which bank financing is limited by high entrance barriers. The alternative financial market does not fully solve but only decreases the problems of information asymmetry and high risk of credit investments in SMEs—but it offers a real solution to the problem of financing of SMEs, as it does not set serious limitations in comparison with the traditional banking system, and uses digital technologies.

It was new digital technologies that provided alternative creditors with a competitive advantage in saving expenditures and increasing the effectiveness of business. Financial establishments used a large branch network for business, which required a lot of investments into real property and personnel. Financial technologies envisage investing mainly in IT systems.

Online lease and factoring platforms became a growing tendency in the world, as they ensure online market, where SMEs could purchase equipment or receive financing from financial intermediaries that purchase unpaid invoices of customers in real time—very often, in the form of an auction. SMEs receive profit from instantaneous increase of liquidity, which allows them to use their potential of growth. Online factoring is also good for startups, as the key link of factoring is financial state and credit history not of the company but its customers, which often are large companies with a long credit history and established reputation.

Crowdfunding, P2B platforms, and P2P credit platforms allow borrowers to apply for credits online and provide all the necessary documents. Initial coin offering (ICO) and other derivatives—e.g., ISO—allow investors to purchase a share in business for tokens. Very often, token is a crypto currency, a digital method of values exchange, which is based on distributed ledger technology. Online platforms and ICO exchanges do not have geographical limitations, as they can receive assets from individual investors, institutional investors, and government bodies from different parts of the world.

The most vivid examples of application of financial technologies in the UN concept "The financial system we need" include the following [12]:

- M-PESA, which created a well-known P2P service of mobile money, started in Kenya almost ten years ago—25 million customers in 11 countries. ANT Financial Services—Alipay—has 450 million users in China and 170 million users in India.
- Borrowers and creditors have been finding each other in the online P2P platforms for ten years, and the sum of provided credits grows annually.
- As of now, fintech has entered the investment industry due to growth of the number of "robot consultants", which manage USD 2.6 trillion in the USA out of USD 30.4 trillion of the (ETF) and the mutual fund market.

It should be noted that the scope of use of financial technologies is very wide, and a lot of technologies are not new—but combination and application of these technologies in the process of digitization create a common transformation potential of the whole financial system. Importance of financial technologies and online crediting in future development of the system of SMEs financing is noted in strategic documents in this sphere. Thus, the above UN document notes the necessity for disseminating financial technologies according to the principles of sustainable development: the role of venture capital and social influence funds in stimulating startups with specific strivings for active growth.

The book by Eva Kaili, Dimitrios Psarrakis, and Raz Hoinaru "New Models of Financing and Financial Reporting for European SMEs" [6] sees the future of the financial system of small business in further democratization, which will reduce the concentration of capital in specific spheres and investment barriers, and increase the access of small business to capital. According to the authors, this conforms to the needs of technological development, which stimulates financial disintermediation. Appearance of crowdfunding and the tools of financing based on blockchain technologies—e.g., ICO—is a result of these technological changes, and they cannot be ignored.

2 Methodology

The purpose of this paper is to consolidate data on the volumes of alternative financing of SMEs and startups, to perform empirical research, and to determine factors that are connected to digital technologies and influence the change of these volumes.

The research is aimed at systematization of the developing topic of alternative SMEs financing and is a logical continuation of the earlier empirical studies [2, 7, 11]. The results of this research could be a basis for further study of the factors that influence the development of alternative sources of SMEs financing.

Empirical analysis uses the annual data of 17 countries of Europe (including Russia) for 2016 and 2017. The research has been performed in three stages. At the first stage, the types of SMEs financing in countries of Europe, including alternative types, have been determined. At the second stage, the factors that could influence the

change of the volumes of SMEs alternative financing have been determined. At the third stage, the authors have collected statistical information on the selected factors and have performed regression analysis for determining their influence on the change of volumes of alternative financing of SMEs and startups.

Analysis of open information sources on financing of the SMEs and startups allowed determining the main types of SMEs financing in Europe and classifying them. All data on the volumes of financing of SMEs and startups by alternative sources have been taken from the study by the Cambridge Centre For Alternative Finance [1, 3]. The data on the volumes of venture financing and bank crediting of SMEs were taken from a study by the OECD [9]. The data on the volumes of lease and factoring were taken from the global data base published by the World Bank [13]. The data on the volumes of ICO were taken from web-site coinsheduille.com,[1] as, according to the experts on the ICO market [4], this web-site is the most complete source of data on ICO and STO. The time period of the data that is used in the analysis—2016 and 2017.

For the purpose of an empirical study of the influence of digital technologies and other factors on the changes of the volumes of financing of SMEs and startups by alternative sources, the authors used regression analysis – in particular, equation of multiple regression for evaluating the influence of several factors. The regression equation has the following form:

$$y_i = a + b_1 x_{1i} + b_2 x_{2i} + b_3 x_{3i},$$

where y_i—dependent variable, namely changes of alternative SMEs financing ; a—constant, which reflects the non-functional part between the dependent variable and factors; b_1, b_2, b_3—regression coefficients of independent factors; x_{1i}, x_{2i}, x_{3i}—independent variables; i—country.

The received model evaluates the influence of the factors on the changes of volumes of alternative financing of SMEs and startups and allows forecasting the change of these volumes.

3 Results and Discussion

As a result of the first stage of the research, the authors determined and classified the types of non-bank financing of SMEs. The results are shown in Table 1.

The main factors that have the largest influence on the changes of volumes of SMEs alternative financing include the ones connected to the influence of digital technologies—e.g., changes of the ICO deals volume for countries and the number of individual Internet users.

[1] https://www.coinschedule.com/stats

Table 1 Classification of the types of non-bank financing of SMEs and startups

I. Traditional financing	III. Alternative financing
– Venture financing – Private financing (business angels) – Lease – Factoring	– P2P consumer crediting – P2P business crediting – Accounts trading – Share crowdfunding – Debt crowdfunding – Crowdfunding based on property security – P2P property crediting – Business crediting based on financial reports – Subsidized crowdfunding – Debt securities – Consumer crediting based on financial reports – Mini obligations – Distribution of profit – Property crediting based on financial reports
II. Financing with the use of blockchain technologies	
– Initial coin offering (ICO) – Security tokens (STO)	

Source Compiled by the authors based on OECD [8], CU CAF [3]

Besides, the factors of changes on the sphere of traditional non-bank SMEs financing were considered: change of the volume of SMEs financing, change of interest rate for SMEs; and factors connected to the changes in the sphere of traditional non-bank financing of SMEs: change of the volumes of venture financing, volumes of lease, and volumes of factoring. Only one factor is significant—change of the venture financing volume.

The aggregate statistics of the data used in regression analysis are shown in Table 2.

The results of regression analysis are shown in Table 3. They show that change of the ICO volumes, number of Internet users, and volumes of SMEs venture financing influence the change of the alternative financing volume (significance of the indicators is 5, 0.1, and 1%, accordingly). The influence of the change of number of Internet users and the venture financing volume is direct, and the influence of the change of the ICO volumes is reverse.

Table 2 Factors of the regression model, the change in 2016–2017

Factor		Min	Max	Average
Change of the alternative financing volume (AF)	y_i	– 15.69	663.49	153.76
Change of the ICO volume (ICO)	x_{1i}	−78.14	2225.05	334.61
Change of the number of Internet users (IU)	x_{2i}	−0.38	10.56	2.61
Change of the volume of SMEs venture financing (VC)	x_{3i}	−82.48	673.13	60.55

Source Compiled by the authors based on the data of 17 countries [1, 3, 9, 13]: UK, France, Netherlands, Italy, Finland, Sweden, Spain, Poland, Latvia, Estonia, Lithuania, Austria, Russia, Czech Republic, Slovenia, Turkey, and Switzerland

Table 3 The results of the regression analysis

Parameter	Value	Standard error	t-value	p-value
a	19.09	43.19	0.44	0.6657
b_1	−0.10	0.05	−2.22	0.0447*
b_2	50.89	10.85	4.69	0.0004***
b_3	0.61	0.17	3.57	0.0034**
R-square	0.7071			
Corrected R-square	0.6395			

***Significance at the level 0.1%, **Significance at the level 1%, *Significance at the level 5%
Source Authors' calculations

Thus, the obtained regression equation has the following form:

$$y_i = 19.09 - 0.10x_1 + 50.89x_2 + 0.61x_3.$$

Determination coefficient 0.71 shows the model's applicability and ability to explain the dependence between the given variables. The model is adequate and well interpreted.

The results of the performed research show that development of digital technologies influences the change of the volumes of alternative sources of financing of SMEs and startups and the conditions of their access to financial resources. The work is limited by a narrow time row of the existing statistical data and, in the course of their expansion, could be the basis for further studies in this area.

4 Conclusions

Analysis of the scientific literature in the studied sphere allowed concluding on the necessity for the following measures, with the help of which new technologies and innovative business models could improve the access of SMEs and startups to financial services and stimulate long-term economic growth:

- improvement of traditional crediting with the use of new technologies and Big Data;
- expansion of the financial instruments, including the capital market;
- increase of consultation functions of financial entities.

Despite the potential social and economic advantages of financial technologies in expanding the access to financial services, usage of innovative solutions remains limited, as compared to the traditional debt financing, due to the following reasons:

- these instruments could be applied only by SMEs with financial and digital literacy and access to reliable information and infrastructure;

- alternative finance—e.g., crowdfunding and P2P crediting—have high risks of losing investments, fraud, information theft, and cyber attacks.

However, this does not reduce the advantages of the digital economy, new IT, and innovations in traditional business models, which stimulate expansion of the access of SMEs and startups to financial resources. Use of the modern technological tools—e.g., cloud services, digital payments, and authomatization of the processes of document turnover and calculations—could help SMEs to increase business activity and obtain additional opportunities of access to various types of financing. Traditional processes of crediting could benefit from usage of online apps and automatization of the processes of proper care verification, credit operations, and execution of normative requirements. Thus, financial establishments could increase their efficiency and reduce operational expenditures—which will positively influence SMEs and startups.

Parametric Architecture and Artificial Intelligence as a Way of Modeling Three-Dimensional Environment

Daria G. Sohatskaya

Abstract The purpose of this article is to study the modeling of three-dimensional environmental space using artificial intelligence and computer programming. We considered the methodology of architectural design and the concept of parametrism as a modern way of modeling architectural space and design. Based on an understanding of architectural design methods, we identified the principles of shaping architectural objects and fragments of the environment in computer modeling of various CAD systems. The authors examined the content of parametric modeling methods in three-dimensional space. We have demonstrated the mechanism of practical application by a person of the parameters of the designed object in software. We have analyzed the combination of irrational and rational thinking in the methodology of architectural and computer design. The article discusses the future development of architecture and design in the future based on parametric architecture. The possibilities of the emergence of the latest styles and trends of parametrism are determined. Artificial intelligence and modern computer technology introduce a number of fundamentally new methods of parametric and compositional design. The synthesis of natural morphogenesis and new parametric modeling takes place at the intersection of interdisciplinarity. The mathematical algorithms of parametrism are wrapped in an aesthetic shell, an ideological essence that is dictated by human thought.

1 Introduction

Man has been improving the environment since the beginning of his existence. The choice of a residential "shelter" was made for several reasons: climatic, protective and geographical. The climatic features of the place of residence, as well as geographical, reflected the features of housing. The causes of housing or any other structure are based on protection from adverse environmental conditions. Given this fact, all primitive dwellings ever found were created by man from natural materials or by nature itself. The main components of the genesis of anthropomorphic space is man.

Today, residential, domestic and administrative buildings are created on the basis of engineering devices and building materials based on the functional features of the premises. Funds for the implementation of projects and the construction of buildings with the development of architectural design are constantly replenished with new developments, including in the field of computer-aided design.

Modern innovative computer-aided design tools allow a person to simplify the process of creating architectural spaces and forms. The interest is concentrated in computational technologies, processes of interaction between nature and technology. This entails the development of the latest tools, methods and materials, which is reflected in the current architecture and design.

2 Methodology

Awareness of architectural design as a form of human practical activity leads to the identification of theoretical methods for implementing this process, which is aimed at presenting its intended purpose, principles, intentions and system.

Architectural design takes into account: the basics of architectural composition, visual perception, socio-cultural, psychological and functional foundations of the formation of the environment; composition and technical features of the structure, content, methods, sources of pre-project information.

In this article, we are interested in the interaction of architectural design methods with artificial intelligence of an electronic computer (computer) and, as a result, the formation of a full-fledged environment.

Basically, the design methods in architecture are based on the creative approaches of various architects, designers, urban planners.

Today, the main stages of design have developed: the preparatory stage or pre-project analysis; stage of sketching or creative search for ideas; stages of creative development; The final stage. Throughout the design process, a logical chain is revealed: "concept" (thought/idea)—development (sketch, drawing)—result (presentation of the finished product, object). To implement the plan, a clear understanding of the laws governing the formation of an architectural organism is required. In the book "Methodology of architectural design" by B. G. Barkhin identifies three main design methods [1]:

(1) Integrated design method;
(2) The method of structural analysis, the principle of designing an object as a system;
(3) The method of problem design.

Designing by a complex method combines the application of general knowledge about man and nature, as well as the theoretical foundations of architecture and urban planning, the use of information on interdisciplinary disciplines.

The method of structural analysis involves the representation of architecture as a system. Here Barkhin [1] distinguishes three subsystems: an object environment, an object process, architectural morphologic and volumetric-spatial subsystem structurally-technical, economic and aesthetic subsystem. This method reflects the analysis of existing data on the projected object, identifies the principles of the solution and anticipates the result.

It should be noted that in the method of problem design, the creative process, detecting an error that interferes in obtaining the result, eliminates it at the initial stage. That is, the foresight of the final projected object is a priority at the very beginning. This method is also interpreted in the method of "assumptions and refutations" of the Austrian and British philosopher Karl Popper. He wrote: "Every "good" scientific theory is a prohibition: it prohibits the appearance of certain events. The more a theory prohibits, the better it is," thus we can say that abstracting from the surrounding "noise", we can take into account factors of influence on a certain situation through the prism of several sciences, or refute them. Thus, the final result can be rebutted at the initial stage of design [2].

D. Luckman's method [3] is based on the search for possible solutions to various design problems. He combined many combinations of constructive models, identifying the real and feasible.

Based on the patterns (patterns) the Cr.V. method Alexandra (Alexander, [4] suggested an analysis of the overall picture at the initial stages of design. This allowed us to formulate a problem in the design, to gradually solve it by detailing the new information found. Thus, a template was formed of unique informational components that interpreted environmental phenomena and human interactions with them. It became possible to design architectural "scenes" not from a "beautiful" point of view, but in accordance with the trends of those who will subsequently use the projected object or fragment of the city territory.

In addition to the use of visual images, sensory experience, knowledge gained, designing is carried out with the help of thinking. Mental skills are used everywhere, but in interaction with thinking, solving problems in practice becomes a whole new level. The irrationality and rationality of thinking in design was investigated by Matchett [5]. His functional design method is based on managing his own thinking process, applying five modes of thinking. They represent setting a strategy and achieving a goal while being in the plane of consciousness of the interviewer. Consideration of the problem to be solved from several points of view, as well as the use of schemes, individual semantic images and associative terms, is also inherent in the modes of thinking according to Matchet.

The study of the connection diagram of the projected object, the structuring of concepts in the form of graphic records involves attempts to simplify the process of architectural design using artificial intelligence of an electronic computer or computer.

Numerous architectural structures created by man in modern times with the help of engineering and technical capabilities represent various architectural and design solutions that are created not only with the help of mental conclusions, drawing and sketching, but also with the help of endless mathematical algorithms in computer modeling.

Any modeling is a way to visually solve a phenomenon, process or volume during a person's interaction with this material-informational formation, which can be called a model.

Any object or its model in space consists of a point, which is marked by some position in space. A line consisting of many points has the following characteristics: length, direction and location. An extended line can transform into a plane and have such characteristics as: length, width, configuration, surface, orientation, location. A plane, like an extended line, can acquire a volume with the following characteristics: length, width, depth, spatial dimensions, surface, orientation, and location.

If for a designer of design tools a sheet of paper, a pencil and a concept in lines and planes become, then in computer design paper becomes a "digital drawing" or a screen with the program interface, which is a toolkit, in this case, an "architect's pencil".

Thus, the volume consisting of points has properties that can be reproduced using computer technology in three planes: x, y, z. Three-dimensional space is a geometric model of the world in which we are. It has three dimensions—length, width and height. Accordingly, three-dimensional space allows you to visually reveal the required qualitative and quantitative indicators of the designed object. He was studied from the point of view of various sciences by such scientists as Aristotle, Euclid, Galileo and Newton, Leibniz and Huygens. Artists XIV-XVI J.D. Bondone

P. Uccello and P. D. Francesca developed the technique of "perspective" or "geometric image" of spatial objects located on the surface. In addition to the fact that the "perspective" takes into account changes in the size of objects with visual perception, this technique provides for the distortion of the outlines of the shapes of objects and the space itself, as well as black and white nuances that create a three-dimensional image.

Currently, computer technology is already broadcasting the use of this technique. They are called computer-aided design systems. CAD or CAD systems make it possible to draw and draw drawings in 2d space, that is, in the two-dimensional space of the x, y axes. Such software may be AutoCAD, CorelDRAW, etc. Complex joints of planes or reproduction of two-dimensional systems of lines is considered in 3d space. Software products in the field of 3d-visualization can be represented by 3D-mach, Archicad, Lumion, Revit, etc. These computer programs use parameters for constructing various objects that have indicators of real objects, structures and fragments of the environment. In addition, in the interface of each of the listed programs there is a list of tools for reproducing the intent of the designer, architect,

and designer. The toolkit is aimed at simplifying the creation of components of various volumes, its design, engineering, economic features. The structure of the computer program retains the ability to transform the object at any design stage.

Computer design allows you to visualize various "scenes" of architectural space with mathematical precision. At the same time, it is possible to create unique volumes and fragments of the environment that have multifunctional properties. It should be noted that in computer design, its information base takes into account in detail all the factors affecting the designed object—economic, constructive, geographical, demographic, cultural. An architectural "scene" can be visualized based on existing computer data.

In the theory of stage art according to Stanislavsky [6] shows the basic technologies of acting: craft, art of representation and the art of experience. It is relevant for us to consider the art of representation and experience. It can be noted here that in the first case, the actor in the process of rehearsing experiences genuine experiences, which are presented as a form of manifestation of these experiences, that is, he "draws" a finished sketch of the role. In the art of "experiencing," the actor experiences genuine emotions during the game, which, in the sum of these two technologies, gives rise to the life of the image on stage. You can compare this concept with the method of architectural design. At the preparatory stage, the architect becomes the user entity of the designed space or object, takes into account its features and characteristics, influencing factors. Having realized the plan, having thought over the concept, he proceeds to the design of the "plot, scene".

So, human engineering is reproduced using mathematical calculations in computer modeling. This assumption is supported by the words of E. Hyman: "In architecture, for example, the use of a computational paradigm helps to derive the concept of an object from very abstract things. The architect conducts a large-scale research of the territory and creates algorithms that should meet his requirements to the maximum. A computer counts large amounts of data" [7].

Currently, parametric modeling is becoming a new tool in 3d modeling. Parametric architecture is created in the Rhino and Grasshopper software package. The toolkit of these programs allows you to create an accurate three-dimensional model. At all stages of design, Rhino can edit and transform, visualize NURBS curves, any surfaces and polygonal meshes. Grasshopper is used by Rhino as a graphical editor of a mathematical algorithm. With it, a person can compose generators of forms of a parametric model. The objective of this software is the ability to design the most ambitious models.

Parametrism as a method of modern modeling helps to change the parameters of the designed object in real time. The first users of this method were architects F. Otto, G. Lynn, L. Spybrook. In his manifesto, Schumacher [8] describes parametrism as a denial of the differentiation of form in the functional plane, preferring multifunctional, permeable spaces under the auspices of individualization.

As mentioned above, the volume has its own physical characteristics, but in parametric modeling, these characteristics become the parameters of the model, which during the design process are constantly adapted and changed in space due to the abstract approach to the environment.

Parametric modeling technologies in architecture are very similar to the idea of the social-symbolic code according to Chertov [9]. Environmental objects possess physical characteristics (properties) and a "code image" located in the cognitive "dictionary" of a person. And in the first and second case, the organizer and "designer" of the environment is a person.

The human idea of a thing (model), like the representation of artificial intelligence, is based on certain parameters and properties of the object. The system of "designing" thought is based on the parameters of environmental objects already known to man. We can say that the visualized object or its volume goes through, first, a certain process consisting of many phenomena, each of which leads to a consequence of something, the birth of an idea and image. The artificial intelligence of an electronic computer (computer, computer) has a database of objects (memory, dictionary) with parameters that take into account factors influencing them: climate and seasonality, history and culture, psychology, physics, mathematics, etc. For example Turning to specialized software in the design of the building, the architect uses his sketches. Aware of the specific characteristics of the location of the future object, he transmits its parameters to the database of artificial intelligence, lays down the structural features of the structure and the materials that will be used in construction.

The main goal of combining computer design and human is the generation of new ideas and concepts not only in architecture and design, but also in the aspect of various sciences.

3 Results

Comparing the data of its "memory" with the parameters set by the person, the computer reproduces the mathematical algorithm, interacting with the provisions of various sciences. Such intelligence is able not only to calculate the design of the projected object, but also to take into account: engineering and technical maintenance, reducing them to a minimum; calculate the influence of seasonal weather conditions on the building, including the ideal position of the building relative to the sun; extrovert interaction of the structure with the environment.

As a result, using computer modeling and artificial intelligence, it becomes possible to design architectural "plots" based on multifunctionality and multifactor using interdisciplinary sciences. In the "digital environment", the architect creates a spatial model of the object, surface or plane of the environment in which it will continue to function. The intent of the person is transmitted in the converted parameters to the computer. So, the combined creative process of two entities "man-computer" form a new tandem for visualization of the thought process and spatial environment.

The design process is getting easier. Complex and multidimensional surfaces, their modification and modification can occur endlessly, reaching ideal technical and economic indicators project [10].

Today, computer artificial intelligence is becoming a partner of man [11], and parametrism brings different directions together. There are completely new styles in architecture and design: parametric urbanism, bionics, morpho-ecological design, digital baroque and morphogenesis, parametric ornament that can form a harmonious space.

4 Conclusions

In the perspectives of architectural design, parametrism stands as the main evolutionary transformation of architecture and design. Artificial intelligence and modern computer technology introduce a number of fundamentally new methods of parametric and compositional design as a whole.

As a result, architectural traditions and digital technologies merge based on a complex system of historically developed human knowledge and the natural characteristics of space.

The synthesis of natural morphogenesis and new parametric modeling takes place at the intersection of interdisciplinary sciences: mathematics, physics, economics, biology, psychology, etc. They provide for the study of parametrism in interaction with each other and are successfully integrated in complex computer design.

Thus, the mathematical algorithms of parametrism are enveloped in an aesthetic shell, the ideological quintessence, which is dictated by human thought and its cognitive activity.

Cloud Technologies in Banking

Elena P. Shatalova and Rasul M. Huseynov

Abstract *Purpose*: Studying the features and prospects of using cloud technologies in world banking in recent years is of great relevance, as among banks, cloud technologies are becoming more popular, and in the field of financial services, the use of cloud-based solutions continues to expand. *Design/Methodology/Approach*: The transition to a digital economy is a global trend. The world has already gained some experience in using cloud technology by banks, however, the question of which cloud service models are preferred by banks, what are the features of outsourcing cloud service providers and the service models they offer, continues to be studied. *Findings*: To date, in international practice, there is successful experience in transferring business functions critical for the bank to the cloud infrastructure, such as accounting and operational activities, risk management and maintaining information security procedures. *Originality/Value*: Modern banks are increasingly becoming IT institutions. A review of current practice shows that the use of cloud technologies by banks not only saves costs, but also acts as a growth driver for the bank, allows banks to introduce innovative products and develop in the institutional aspect. In Russia, the development of cloud technologies is a factor contributing to the development of Russian regions, as it creates the infrastructure for the formation of regional financial centers, which allows to solve the problem of disproportional development of Russian regions.

1 Introduction

Currently, the world has already gained some experience using banks with cloud technologies, however, the question continues to be studied to what extent banks from different countries, including global banks, use public cloud services. Studying the problem of using cloud technologies by banks also includes studying the real and perceived barriers to introducing cloud services in banking.

The use of cloud services by banks is affected by legal and regulatory issues, as well as the regulation of outsourcing of cloud service providers offering several service models.

Cloud technology is a model for providing convenient network access on demand to the fund of configurable resources (from storage systems to business services) that can be quickly provided, scaled and freed up with minimal operating costs and contacting the supplier.

For banks, harnessing the potential of the clouds helps to increase capital adequacy (relevant to the recent global financial crises and Basel III recommendations), reduce operating costs, maintain capital and profit, and remain competitive. The transition from a traditional economy to a digital one is a global trend [1]. Innovations and relevant technologies are now becoming the most important factors of economic growth in the modern conditions of the formation of the information economy [2].

The issues of liquidity and profitability management are currently relevant for each commercial bank, a lot of work is being done to optimize this sphere of banking activity [3].

However, cost savings are not a major factor for banks, which are increasingly becoming IT institutions. Banks should not use the cloud, only to save money, in the case when they could use the cloud services to provide services transferred to third-party "traditional" integrators on their own. Banks can consider the cloud not just as one of the tools to reduce costs, but as a "growth driver" that allows them to simplify their work, introduce innovative products and increase efficiency, which will allow banks to focus on adding value to customers.

For Russian conditions, the development of cloud technologies has another important aspect. Russian scientists are exploring regional differences in the spatial distribution of banks between Moscow and the federal districts of the Russian Federation, as well as subjects of the federation and their capitals, identifying features of the existing hierarchy between regional financial centers and factors explaining why such financial centers were formed outside the capital. Studies have shown that regional financial centers appeared despite the concentration of financial institutions in Moscow [4]. From our point of view, the development of cloud technologies in banking is a factor contributing to the development of the Russian regions, as it creates the infrastructure for the formation of regional financial centers.

2 Materials and Method

Over the past few years, discussions have been actively held about the features and prospects of using cloud technologies in banking. Among banks, cloud technology is becoming increasingly popular. At the same time, there are both positive reviews and forecasts of the introduction of cloud technologies in banking, and sharply negative.

Currently, in the field of financial services, the use of cloud-based solutions continues to expand, problems are being investigated, the solution of which becomes possible in the digital economy, which is reflected in publications of Ageeva and Mishura [4], Ferrer et al. [5], Stavrinides and Karatza [6], Konovalova [3], Mell and Grance [7], Magee [8], Taghavi et al. [9], Raza et al. [10], Sullivan [11], Hon and Millard [12, 13], Costache et al. [14], Travkina and Annenkova [1], Yudenkov [2].

3 Results

The following cloud service models are currently distinguished:

1. Cloud Software as a Service (SaaS)—cloud software as a service;
2. Cloud Platform as a Service (PaaS)—a cloud platform as a service;
3. Cloud Infrastructure as a Service (IaaS)—cloud infrastructure as a service.

In addition to the above models, a variation of the second model, denoted by the abbreviation iPaaS, is a distribution platform for integrating cloud services among themselves, as well as cloud services with local IT systems of a consumer company.

Different deployment models are possible for cloud services [7]: public, private, or hybrid cloud and cloud community, each of which may include IaaS, PaaS, and SaaS. Two main deployment models: a public cloud (public, or public cloud) and a private cloud. Public cloud involves the use of standard real equipment, which is distributed between different customers or "tenants". Banks mainly practice using public cloud services.

A private cloud is designed for a specific customer. It can be managed by the client himself, and is often localized in the client's premises. But a private cloud can also be located outside the client's premises, for example, in a data center of a service provider or a system integrator who creates and manages a cloud for a client. This type of private cloud is closest to classic traditional outsourcing. Private clouds can be physically separated, albeit at a higher cost. For example, the servers used only by this client are allocated. Customers choose how to connect to their private environment with an Internet provider, their own data centers and internal networks.

The term "hybrid cloud" tends to be used in two cases: either the case of "breaking" a private cloud to access the public cloud from its own customer data centers for additional capacity during peak demand periods, or the storage of some (usually sensitive or confidential) data and its processing in their own data centers, but other data and their processing is carried out in a public cloud.

The community cloud includes a group of unrelated organizations with common interests that use the cloud service, which is private only for this group.

A type of private cloud is a virtual private cloud or VPC. VPC refers to a cloud service that allows multiple tenants to use the same physical equipment as in a public cloud. However, providers claim that VPC offers improved security by providing each tenant with remote access to cloud computing resources through a virtual private network (VPN).

Cloud computing is essentially related to the use of network computing resources, usually on demand scalable Internet [12].

In cases where the resources used are software applications accessible through a web browser on the local cloud user device, but installed and running on remote cloud servers, the service model is indicated by the term Software-as-a-Service (SaaS) [7], Software applications available through SaaS vary, but may include website hosting, data storage (e.g. Box, Dropbox), as well as customer relationship management (CRM), HR, accounting and financial management (e.g., Workday), are Work on text messages, email and other office applications [e.g. G-Suite (formerly Google Apps for Work) and Microsoft Office 365], sharing photos and files (e.g. Flickr) and social networks (e.g. Facebook) [6].

If the IT resources used on the network are computing power, that is, servers, storage, networks, the service model is called Infrastructure-as-a-Service (IaaS). The cloud provider manages the equipment, but the IaaS client must independently manage its virtual machines (VMs), including the operating systems and applications that it installs in its own virtual machines. Thus, customers can use IaaS services (virtual servers, storage, networks) for everything they choose, taking into account contractual restrictions imposed by the provider [9].

If the relevant IT resources include application hosting and deployment platforms that enable software applications that have the source code downloaded by the cloud client, the service model is known as Platform-as-a-service (PaaS) [14]. Examples include the Google App Engine (part of the Google cloud platform), IBM's Bluemix (built on Softlayer), and Microsoft Azure. As with IaaS, cloud clients can be flexible about how they want to use PaaS. Some PaaS platforms can be installed in their own client data centers, such as Open Source Pivotal Cloud Foundry, which can be hosted on Openstack (the open source IaaS platform) [5].

Instead of using a specific SaaS service, one can create equivalent software on IaaS/PaaS, given the sufficiency of experience, resources and time. However, in this case, the client, as a rule, is more efficient, convenient and economical to use the SaaS service, which already provides the required functionality [10].

Today, in international practice, there is successful experience in transferring business functions critical for the bank to the cloud infrastructure, such as accounting and operational activities, risk management and maintaining information security procedures. In this case, as a rule, a public cloud infrastructure is used from one of the technological giants, such as Amazon, Microsoft or Google.

Thus, in 2015, the largest digital bank, Capital One (USA), completely migrated its IT system development and testing environments to Amazon Web Services (AWS, USA) in 2015, and in 2017 built the processes of migration of main services to AWS

and formed a team in several thousand certified cloud engineers. By the end of 2018, Capital One plans to abandon 5 of its 8 own data centers in favor of a cloud infrastructure in the PaaS format.

Bunq Digital Bank (Netherlands) has completely migrated its IT systems to Amazon Web Services for IaaS in two years. Bunq remotely provides its services to customers in the Netherlands, Germany, Austria, Italy and Spain from the Amazon data center in Frankfurt.

In addition to the scenarios of migration of the bank's automated banking system (ABS) infrastructure to the public cloud infrastructure, there are several cases of the creation of initially cloud-based banking IT systems.

So, DBS Bank (Singapore) opened DigiBank in India—a mobile client bank in the public cloud, which uses the accounting and operating system of the parent bank, located on private infrastructure.

Atom Bank (Great Britain) is a mobile bank without branches and a website; it is developing on a cloud integration platform from the supplier MuleSoft (USA). Using the cloud integration platform (integration Platform as a Service, iPaaS) allowed Atom Bank to implement straight-through processing of applications for mortgage lending.

Oaknorth Bank (UK) provides online credit and deposit products to small and medium-sized businesses using the cloud-based automated banking system of Mambu (Germany) [11]. The launch of an automated banking system (ABS) in the PaaS format cloud has accelerated the launch of products on the market from several times a quarter to several times a week, which means the ability to quickly adapt to changing customer requirements.

Monzo Mobile Banking (UK) has developed a cloud-based automated banking system (ABS) to host its systems on Amazon Web Services (AWS) infrastructure. Compliance with the UK Financial Regulatory and Supervisory Authority (FCA) requirements for auditing operations in IT systems is ensured by AWS CloudTrail technology [15].

HSBC has worked with Google, Amazon and Microsoft to transfer some of its data to the cloud services [8]. Representatives of HSBC Bank said that the transition to the cloud was an important way to reduce the budget of the bank's IT department. Depending on the area where cloud services are used, the cost savings for the bank could be 50%, but in some cases, HSBC could eliminate up to 90% of costs [13].

Financial organizations should be able to reduce their costs due to the "collective" implementation in the cloud services of those functions that are not their competitive advantage. This primarily concerns automated banking systems, the preparation of regulatory reporting and certified cryptography.

1. The business models that implement cloud technologies in banking include the following.

   A niche fintech company is an organization with expertise in a narrow field, such as remote banking or credit scoring based on an analysis of user behavior of a retail client on the Internet. An example of such a company is Rocketbank (Russia), which specializes in providing a convenient mobile client bank, working

on the basis of the infrastructure of another bank in the BaaS format (Banking as a Service—a service for banks to lease their infrastructure) under a license from Kiwi Bank.

2. Distributor—an organization that is a supermarket of financial products, where consumers can compare offers and make a deal with those who offer more favorable conditions without leaving the platform. The key competence of the distributor is to gradually build up the customer base through a large number of suppliers and attract new suppliers by increasing the number of customers (the so-called "platform effect"). For example, the financial group ING (Netherlands) provides the opportunity to purchase both its own products and products of other banks through its platform.
3. A food factory is a financial organization that specializes in developing business processes and introducing services such as loans, deposits, insurance products, financial management services, operations with guarantees and letters of credit, and other related services to the financial market. The main goal of such an organization is to maintain a balance between financial stability and the availability of the opportunity to offer customers financial products on favorable, competitive terms. An example of food factories are large financial groups—Credit Agricole (France), Allianz (Germany), Sberbank (Russia).
4. A technology company is an organization that has expertise in the field of creating highly loaded, scalable and flexible IT systems. The key competence of the integrator is the ability to implement a turnkey ready-made IT solution for the consumer, consisting of many different IT systems.

To develop and support cloud infrastructure, a technology company may offer the following services:

1. The implementation of open API,[1] which includes the development of standard software interfaces to the IT systems of financial institutions, as well as the provision of a technological environment for messaging. For example, SaltEdge (Canada) provides services for the integration of internal IT systems of financial market participants using open API in accordance with the requirements of the Second Payment Directive of the European Union (PSD2).
2. Placement of several competing services on the cloud services marketplace, where customers can pilot the business services (BaaS) of several suppliers in parallel and develop cooperation with companies that provide the most suitable solutions. the cloud services marketplace can simplify the conclusion of contracts between participants who have signed a framework agreement with the trading platform, provide hosting services, monitor the quality of services, billing.

Cloud computing can drive bank growth by supporting product development and innovation processes, as well as increasing flexibility and reducing time to market.

The outdated systems used by the bank for decades can act both as a driver and as a barrier to cloud implementation. On the one hand, cloud services can be more

[1] API—application programming interface.

secure than outdated and poorly supported outdated bank IT systems. On the other hand, if a bank does not have a comprehensive understanding of its longstanding old systems, migrating to the cloud can be a daunting task.

4 Conclusion

The use of cloud solutions can reduce the barriers to market entry for innovative companies. Simplification of integration between participants in the financial and technological sectors will help reduce transaction costs and increase the transparency of outsourcing schemes, which will increase the rate of adaptation of financial institutions to changing market conditions.

The introduction of cloud solutions gives rise to several new features of banking practice.

Firstly, it becomes possible to use cloud services without involving IT specialists, but for the safe storage of customer data, these specialists are necessary. Secondly, most banks choose a private (private) cloud, especially for basic banking operations and everything related to customer data. Thirdly, the need for customers to keep in touch with the bank in mobile and online interfaces is increasing.

It is worth noting that complex solutions in the cloud infrastructure can be better than the solutions implemented in the bank's own infrastructure. In particular, access to the widest possible data set provides an advantage in areas such as credit scoring, anti-fraud, money laundering and terrorist financing.

Under Russian conditions, cloud technologies will contribute to the formation of regional financial centers, which will play a positive role in smoothing the imbalances in the uneven economic development of the regions. The development of cloud-based financial infrastructure will create a competitive environment and conditions for the transition to a qualitatively higher level of development for the financial sector.

The Power of Modern Digital Technologies for the Specialist Training in Artificial Intelligence

Zhanna S. Afanasyeva and Alexander D. Afanasyev

Abstract *Purpose*: The purpose of the article is to present a set of methodological recommendations to introduce Modern Digital Technologies in the educational process that can be used for training in Artificial Intelligence including preparation for Bachelors' and Masters' degrees. *Design/Methodology/Approach*: The authors note that in the modern education system the navigation through educational online resources and competent use of such sources of information to obtain relevant knowledge and skills are becoming important. We must accept that contemporary development of education changes the role of a lecturer. A professor is no longer a central figure in order to transfer the knowledge to students. Currently a professor should be a moderator as well so that students can obtain the necessary competence. The authors describe approaches to organizing full-time student learning using a set of Modern Digital Technology tools such as the Kaggle platform, the Google Service—Colaboratory (Google Colab) and the Stepik educational platform. Website Kaggle demonstrates a World-Class level of development in Artificial Intelligence. The Colaboratory resource reduces entry barriers associated with limited technical and software resources for studying Deep Learning and online experiments with neural networks. Stepik is a service to organize online learning. *Findings*: It is shown that the use of digital tools provides an increase in the effectiveness of the educational process, mobility and a differentiated approach to study training materials. *Originality/Value*: A set of methodological recommendations on the use of digital education tools was developed. The proposed methodological recommendations give an opportunity to introduce the powers of digital resources for educational purposes. The advantages of using Modern Digital Technologies providing opportunities to students for professional growth and personal development are shown.

1 Introduction

Modern trends in the development of education in the world set different rhythms and approaches to gain knowledge. Most demanded professional competencies these days can be obtained and evaluated remotely from almost anywhere in the world.

An open educational system has brought about a shift in focus from the educational activities of an instructor to the productive educational and research activities of students, to the creation of conditions for their active independent work. In this case, a fast feedback, a competitive spirit, an access to the global educational and professional space, and the solution of real practical problems become important. The resources as the Kaggle competitive platform [1], Stepik educational platform [2], and the Google service Colaboratory [3, 4] allow us to realize this in the educational process.

2 Methodology

A great way to immerse into Deep Learning is to look at learning AI through Kaggle Competition Site. A creator of Keras and Google engineer François Chollet shared that view [5]. The combination of Kaggle and Colaboratory Resources in the study of neural networks is used by both beginners and advanced specialists [6, 7]. We transferred this best practice to full-time students organization and added an online course to it.

The inclusion of these three components in the educational process—Kaggle, Colaboratory, Stepik—allowed us to obtain a synergistic effect in improving the quality of education.

One of the opportunities to determine the level as a specialist in the field of artificial intelligence (AI), to complete traditional training tasks, to learn the experience of experts and to join the solution of a specific practical problem is provided by the Kaggle platform.

International AI competitions are held at Kaggle. Kaggle allows users to find datasets for free use, multi-level free training courses on relevant topics in AI, ready-made Python codes for solving problems considered at competitions. The site has a convenient intuitive navigation.

You can search for the necessary sections using thematic tags (Deep learning, Classification, Data Cleaning, etc.).

The main opportunities available on Kaggle are such as follows:

- To take part in the competition and see your international rankings (Competitions);

- To improve your results in solving a specific problem, analyzing the ready-made solutions of competition participants, including qualified specialists (Notebooks, Kernels);
- To use a ready-made dataset for your research (Datasets);
- To offer your dataset for a public use (Your Datasets);
- To discuss the problem that is relevant to you at a discussion board (Discussion);
- To publish your code to be evaluated by other participants;
- To offer your code to solve a practical problem with ready-made datasets (Tasks);
- To use the Kaggle server as an online environment for programming in Python and R in the Jupyter Notebook command shell without installing additional software using Google Cloud Services (Notebooks ⇒ New Notebooks);
- To take training courses (Courses);
- To organize a commercial competition to solve your problem or a closed competition for students of your training course (Kaggle InClass competitions).

Kaggle should be perceived not only as a platform for participation in competitions, but mainly as an expert environment where you can learn from the experience of professionals, evaluate what approaches are used in AI and how successful they are, to improve your skills [5, 7]. The Kaggle profile takes a significant place in the portfolio for employers.

One of the most popular classical training competitions for beginners is the "Handwritten Number Recognition MNIST" ("Digit Regognizer") [8]. "Dogs vs. Cats" competition [9] is an example of the classical classification task using neural networks. "Titanic: Machine Learning from Disaster" competition [10] is a well-known classification task and a good example of exploratory data analysis using the Data Science tools and Machine Learning Algorithms such as Logistic regression, Random Forest, SVM and so on. An example of solving the regression problem is a house price prediction competition "House Price: Advanced Regression Techniques" [11]. One of the recently announced competitions is to detect a video generated by the AI "Deepfake Detection Challenge" methods with an impressive prize pool of $1 million [12].

To participate in competitions, to get an access to Kaggle datasets and other resources, you have to register step-by-step, to create the Kaggle API Token (kaggle.json) for later use. In most cases, the competition requires you to "accept rules".

Quite often, when you first try to submit your decision to the "Digit Regognizer" competition, a 403 error occurs—"You cannot submit until you accept the competition rules". To avoid this, we recommend the following sequence of actions:

- To create an account;
- To activate the account from your mail using the reference and create kaggle.json;
- To log out of the account and go to the competition page "Digit Regognizer" and click on "Join Competition".

After this, it is important to verify that in the Rules tab the message "Rules acceptance is not required for this competition. Good luck!" has been changed to "You have accepted the rules for this competition. Good luck!".

If this does not happen to submit your decision is useless, there will be an error. Then you need to log out of your account again and repeat the steps indicated earlier. Unfortunately, repeated attempts can lead to the account being blocked, then you need to delete both the account and kaggle.json; to create a new account and perform all the actions in the recommended sequence.

The next power of Modern Digital Technologies we use is the organization of Electronic Learning through an automated distance learning system.

Our courses "Introduction to Python", "Intro to Deep Learning", "Artificial Intelligence and Machine Learning", and mid-term and end-of-course assessments have online-support on the Stepik.org educational platform. In addition, to implement the individual educational programs of students, we recommend courses by other authors on Stepik and on other educational platforms.

The courses contain the necessary theoretical sections, links to useful Internet resources and literature, chat for students and instructors and automate the screening of tasks, including Python code. About 20 types of steps are available to create training and monitoring tasks: text, video, test, numerical and text tasks, programming, sorting and matching tasks, table task, etc.

Every participant of the course can choose a section with different exercises: basic, sufficient, high. Course navigation is available in six languages, including English and Chinese.

There is a ranking system for assessing students' educational levels on the course. This scoring system leads to self-realization and self-assertion. At the same time, it is possible to limit the time for completing a task, to take points for an erroneous answer according to the selected scheme.

In addition, the chat room and solution board provide a range of opportunities for both students and instructors such as follows:

- Continuously to develop and enhance the quality of the offered tasks through feedback from students and monitoring errors;
- To get instructor's advice outside the classroom;
- To discuss emerging issues with classmates;
- To learn from others studying their code and thereby improve students' skills;
- To have an opportunity to get instructor's recommendations to modify the programming code.

The challenge for students is to come up with their own assignments to form a creativity to solve problems and motivate students' cognitive activities. Students' best assignments are included in the training course.

Furthermore, we use "the flipped classroom" technology.

We can control the individual activity of each student by days, by the number of tasks solved, by mistakes made in a visual form through a weekly progress report and course digest.

We use both private (closed) and public (open) courses.

For more convenient monitoring of student learning in the case of a public course, a special group-class is formed by reference—an invitation to join the course.

The online course helps to save instructor's time on explaining new materials, reinforcing students' knowledge and skills as well as monitoring the active participation of students in the course.

An access to the course at all times allows the student to effectively plan his time for studying the course, to choose the individual learning rate, including using a mobile application. In addition to this, the course is the best resource for those who are lagging behind.

Thus, we solve didactic and methodological problems to manage the educational and cognitive activity of students, to plan and personalize the educational process, and to implement adaptive learning by the online course.

E-learning allows a comfortable environment for efficient communication, training and creativity, providing continuous education, which certainly affects the quality of education changing its form, making it more accessible and effective.

To implement training courses, you need a stable Internet connection. For the students' practical work, powerful computers and software are not required provided the educational process is implemented using cloud technology. The use of cloud technologies is of great help.

One of the main used cloud Google servers is the Colab Laboratory server (Colaboratory). Colaboratory is a powerful tool for machine learning education and online research of neural networks. The service provides GPU and TPU accelerators for Deep Learning. With Colaboratory you can write and execute code (notebooks) for Production deployment and participation in Kaggle competitions.

Colaboratory is based on a Jupyter notebook environment. Keras, TensorFlow and the necessary libraries for programming in Python are preinstalled in it, computing power is provided for free. Created notebooks are automatically saved in ipynb format on a Google drive. Colaboratory contains a beginner's guide and examples of machine learning models [3].

3 Results and Conclusion

It is possible to conclude that using Modern Digital Technologies for training in AI greatly contributes to the relevant training solving modern problems in various applications.

The benefits of the Modern Digital Technologies tools introduction to full-time students, are namely such as follows:

- Kaggle platform allows to adopt the world experience in the application of AI;
- Colaboratory reduces entry barriers associated with limited technical and software resources for studying Deep Learning and provides an opportunity for online experiments with neural networks;

- The Stepik educational platform is used to implement a continuous learning process through an online course as a supplement to the primary course.

More importantly, the learning process becomes exciting and motivating not only for students but also for instructors.

The Effectiveness of the Artificial Intelligence Development as a Factor in the Nonlinear Development of Social Systems

Alexander A. Berzan, Alexey V. Gubin, Alla V. Pavlova, Stanislav N. Vasilev, and Tatyana V. Skudalova

Abstract From the perspective of the nonlinear forecasting methodology, the prospects and risks of the emergence of artificial intelligence are revealed. The reasons for optimistic forecasts, as well as threats in the "horizons" of the singularity due to the creation of machine mind are revealed. Special attention is paid to the concept of a friendly smart machine in an intelligent explosion. An attempt has been made to philosophical reflection of several options for pernicious failure, namely, vicious implementation and infrastructural redundancy. The relevance of this topic lies in the fact that the topic is not well understood, additional research in the field of artificial intelligence is required. One of the main factors that influence the relatively sustainable development of man and social systems is the emergence of activities that, as the forms, means and methods of innovation become more complex, gradually become technologies. Their potential and technical implementation in various spheres of life since ancient times influenced the formation of the scientific rationality of the modern type, which undoubtedly correlates with the emergence of the information society with its characteristic strengthening of the role of statistical laws and the non-linearity factor. The future becomes both "better" from the present in strictly defined parameters, and "worse" in other parameters. And technologies, especially knowledge-based, which can cause an existential crisis of global proportions, get an important role.

1 Introduction

Since the mid-twentieth century, science has played a leading role in the system of social production, and high-tech technologies have begun to claim the role of a new attractor, which determines the vectors and axiological horizons of the development of social systems. But the more complex the social system, the more it is affected by stochastic factors, which create a non-linear space for further development paths that are formed as a result of the actualization of phase transitions—forced responses of a nonequilibrium structure to the threat of reduced stability. In this context, progress acquires the character of an end in itself, not value, but appears as a way of preserving complex integrity. The ways to achieve this state are non-linear, because it is impossible to calculate their quantity, degree of determination and danger for a certain period of time. The resolution of certain contradictions "launches" a nonlinear chain of many other, new, even more ambiguous problems. In the future, this determines the emergence of vectors of evolutionary changes: from more stochastic ("natural") to less likely states. According to the non-linear model, progress as "separation from the natural niche" means the restoration of the relative stability of the system at a higher level of disequilibrium. In the light of what has been said, it should be emphasized that the "technologicalization" of society and progress constitute an inextricable unity, but, unfortunately, not always organic, as the subject of the historical process would like. Today, scientists and philosophers recognize that it is high technology that is the factor and attractor that determines the development of social systems, and science has long turned into a productive force, which from time to time, ignoring humanistic ideals, drives itself into a cynical sphere, indicated by the idea that "The end justifies the means."

Any high-tech technology can both launch a non-linear space of new risks and become a potential source of threat. And in this sense, the problem of artificial intelligence becomes especially interesting. The creation of a thinking machine, like itself, is a process with an acute leakage regime, one of the distinguishing features of which is the growth of micro-fluctuations, as a result of which "the mouse gives rise to a mountain". In a nonlinear and unstable social system on a planetary scale, this can have disastrous consequences, contrary to the numerous opinions of the apologists for this technology, because any technical innovation can be used both for evil and for good. In the future, artificial superintelligence can create a self-reproducing machine of molecular collectors, called nano-assemblers, making a promise to humanity that their experience in using it will bring only benefit. Infinite optimism also fuels a complex of complex psychological reasons, the totality of which is called "anthropomorphism"—extrapolation of human qualities to the possibilities of a super-intelligent agent [1, p. 224].

Artificial intelligence is a qualitatively new one in the technological sense, according to N. Bostrom, since its appearance will change the essence of progress, excluding people from this process.

2 Evaluation Methods

The essence of the methodology for evaluating the effectiveness of the development of artificial intelligence is to evaluate the very parameters of the forecast model, which minimizes the development deviation from the points of the initial time series, i.e.

$$P = \sum_{i-1}^{k} (\hat{y}_i - y_i) \rightarrow \min, \tag{1}$$

where

$\hat{y}_i$—estimated value of the initial series;
y_i—actual value of the initial series;
k—number of observations.

If the evaluation model is presented in the form $\hat{y} = f(x_i, a_i, a_2 \ldots, a_k, i)$, where

$a_i, a_2 \ldots, a_k$—model parameters;
t is the time;
x_i—independent variables,

then, in order to find model parameters satisfying condition (1), it is necessary to equate to zero the first derivatives of P with respect to each of the coefficients. Solving the resulting system of equations with k unknowns, we find the values of the coefficients a_i, a_2. Solving the resulting system of equations with k unknowns, we find the values of the coefficients a_i.

The use of the least-square estimation procedure involves the mandatory satisfaction of a number of assumptions, the failure of which can lead to significant inaccuracies.

The use of a nonlinear form as the most complex and sufficiently satisfactory source data creates a dynamic problem of predicting the regression equation, which will look like:

$$\hat{y}_t = a + bi, \tag{2}$$

where $\hat{y}_t$ found value y_t, in a given time interval t;

a and b are constant values that invert the sum of the squares of the deviations of the obtained values y_t from the calculated $\hat{y}_t$ to a minimum.

Using this method, we obtain an equation of the form

$$\frac{\partial}{\partial a}\sum_{i=1}^{n}[y_i-(a+bt_i)]^2=0;$$

solving which we get a normal equation

$$\sum_{i=1}^{n}y_i=na+b\sum_{i=1}^{n}t_i; \tag{3}$$

Therefore,

$$b=\frac{n\sum_{i=1}^{n}t_iy_i-\sum_{i=1}^{n}t_i\sum_{i=1}^{n}y_i}{n\sum_{i=1}^{n}t_i^2-(\sum_{i=1}^{n}t_i)^2},$$

where b is the regression coefficient characterizing the slope of the regression line (slope tangent);

$$\mathrm{a}=\frac{n\sum_{i=1}^{n}yt\sum_{i=1}^{n}t_i^2-\sum_{i=1}^{n}t_i\sum_{i=1}^{n}y_it_i}{n\sum_{i=1}^{n}t_i^2\left(\sum_{i=1}^{n}t_i\right)^2}.$$

or

$$\mathrm{a}=\frac{1}{n}\left(\sum_{i=1}^{n}y_i-b\sum_{i=1}^{n}t_i\right),$$

where a is the free coefficient characterizing the intersection of the y axis with the regression line, i.e. is equal to y_iпри $i=0$.

More than fifty countries are currently developing militarized thinking machines. And there are already the first manifestations of poor-quality programming that entailed terrible consequences: during military operations in the Middle East, combat drones equipped with automatic weapons, after being used against their own, were disabled. The failure of the robotic anti-aircraft gun program resulted in the death of nine and severely injured fifteen soldiers of 2017 on the African continent (see: [2, p. 128]). Very symptomatic is the fact that the duration of this incident was less than a second. So, there is an opinion that discussions about ethics and technical innovations take place on different planets. The concept of techno-humanitarian balance postulates the need for an appropriate spiritual level of civilization for an adequate "grinding" to technological innovations of various degrees of complexity (see: [3]). The technology of artificial intelligence, like nuclear fission, like many others, is a dual-use technology.

As a rule, the discussion of the dangers associated with artificial intelligence occurs in isolation from the context, with the substitution of concepts and is not marked by a professional assessment and analytical depth. It is clear that in academic

scientific and philosophical circles this problem is not avoided, but most often it is not given due attention. Most experts consider the creation of artificial superpowerful intelligence only a matter of time and are in pleasant euphoria from those prospects that are looming on the horizon. As soon as it comes to unpleasant forecasts, many media representatives (technical journalists, bloggers, editors) reflexively do not take them seriously. Such a reaction is determined by the usual unwillingness to reach the essence of the problem, which indicates the insolvency of the counterarguments put forward by them. For the majority of ordinary people on whom the media products are designed, the problem of an artificial intelligent agent seems to be something far and abstract, and therefore, it is not a matter of primary importance for journalists. The entertainment sphere is more attractive to technical journalism: plasma on quantum dots, more capacitive storage media and other new products of the software market.

3 Problem Solving Approaches

Today, no one is faced with any serious event that has tragic consequences, to the beginning and to the foundation of which an artificial intelligent agent would be involved. Artificial intelligence is not yet regarded as a source of existential threat. It is believed that in order for humanity to evaluate all kinds of risks that artificial intelligence may cause, it needs to be on the verge of life and death. A clash with a mind that surpasses ours will have nothing to do with terrorist attacks, nuclear winters and other disasters that are endo-technogenic in time and space. As a result of the actualization of the scenario, which escaped from the uncontrolled artificial superintelligence, the global human race, obviously, will leave only a trace in the form of fairy tales that will tell the works to their children before going to bed. Also, one of the reasons for the incorrect assessment of artificial intelligence as the beginning of the countdown to the existence of civilization is the fact that the phenomenon of an artificial intelligent agent was reflected in another controversial phenomenon called the “singularity”. The concept of “singularity” is widely used in scientific and philosophical circles and has a different contextual-semantic coloring. In the article, the use of this concept has the meaning invested in it by R. Kurzweil, who understands this as a measure of the transition of quantity into quality, in which a leap in technological progress fundamentally transforms human being. The mind will cease to be exclusively a human prerogative and, according to R. Kurzweil, will become more computerized, which will make it many times more powerful than today. The author of this concept is optimistic, believing that such a transition will eradicate such negative phenomena as hunger, illness, and, possibly, in the future, a person will gain eternal life (see: [4, pp. 136–147]). According to G. Kurzweil, an artificial smart agent will affect a fundamentally new qualitative transition of world civilization, but, as already noted, this will entail the development of related branches of high-tech nanotechnology [4, 47]. Forecasts by experts indicate that an intellectual explosion and the subsequent emergence of artificial supernatural will inevitably lead to a sharp jump in the development of nanotechnology. Many experts believe

that the artificial superintelligence should belong to the priority due to the fact that nanotechnology is too stochastic a tool that can be impossible for a person to control. It becomes clear why optimism in the context of singularity comes precisely from the sphere of nanotechnology development, and not from artificial intelligence. Most experts involved in the field of high technology do not analyze the more skeptical third option, the essence of which is that the final stage in the development of smart agents, and then machines that are superior in human intelligence, will not be a harmonious union of artificial intelligence with natural, but transformation human raw materials for the "triumphal promotion" of a new subject.

The interaction of the "traditional" human mind with the supermind of the machine is identical with the expansion of the spheres of influence of technological Western civilization on agrarian-type societies, or assimilated them, or turned into their own resource. It is likely that theorists in the field of high technology have already comprehended all the "dark sides" of artificial intelligence, but, having analyzed all the pros and cons, they came to the conclusion that the end justifies the means. Or they understand that the point of no return has been passed and accept the inevitability of any result, postulating the impossibility of changing something. An idea has been put forward according to which a person will be able to comprehend and discover ways of protection against a progressive machine mind only in the process of integrating this phenomenon into our society.

A significant breakthrough in the system forecasting methodology was made within the framework of a nonlinear methodology initiated by the theory of self-organization of complex systems. Depending on how open systems of various nature are capable of converting the internal heterogeneities of their structure to useful potential, while maintaining and increasing the level of organized complexity and relative stability, the researchers were able to systematize the specifics of the flow of regimes with aggravation, as well as ways to eliminate fluctuation deviations that lead to crisis conditions. Analyzing the prospects for the emergence and development of artificial intelligence from the standpoint of a non-linear approach, it is necessary to introduce into the prognostic model data on the specifics of the artificial system, development trends, threat levels, and non-linearity vectors. Predictive modeling with an unaccounted for nonlinearity vector does not reflect the entire complexity of the process and is linear. We deal with such shortcomings when confronted with prognostic models that are associated with artificial intelligence technology. In this regard, do not underestimate the creative potential of evolution, the stochastic influence of which is not something constant and stable. And from this position, the process of self-improvement of the artificial mind will probably one way or another meet the criteria of evolutionary development. A. Azimov in his writings put forward the thesis that cognitive models can be identical with the components of the psyche, in other words, he suggested that the work could evolve. His idea of "ghosts in a car" is now gaining new meaning. He talks about the possibility of the emergence of randomly generated protocols, which in the future can develop into what we call behavior, and unforeseen free radicals can initiate creativity, freedom of choice, and possibly the soul (see: [5, p. 253]). It is also worth considering that the occurrence of artificial superintelligence belongs to the category of those events from which the

consequences can be global, and the probability of occurrence is low since nothing like this just happened and the empirical component of humanity is zero. To come to an unambiguous solution, armed with traditional statistical methods, the task is not an easy one. In the process of developing an artificial mind, it should be borne in mind that specialists cannot afford the right to make mistakes. In a process with a sharp flow pattern, this can have the consequences of a "butterfly effect" and as a result we get something completely alien. This can be compared with the actions of a bear cub by breaking into a super-complex safe under the alarm in the bank. If he presses nineteen correctly with twenty digits of the code, then the doors will not open by five percent, they will remain locked. When creating artificial intelligence, an error of even one hundredth of a percent will result in a hundred percent unpredictable result. He will not be almost good, he will be completely bad. Most of the technologies familiar to humans are potentially dangerous for her, like any innovation—a "double-edged sword", as already mentioned. Obviously, artificial intelligence is no exception. It will not show negativeness to you, but it can find other uses for your atoms. Creating artificial intelligence with good intentions and extrapolating these positive emotions to the machine, experts mistakenly believe that this is a guarantee of the emergence of friendly characteristics. Such shortsightedness is associated with the already mentioned demon of anthropomorphism and linear determinism, which does not take into account fluctuations of varying degrees of importance. The homosapiens arose in the process of self-organization of matter, which involves the struggle for free energy, information and matter. And, if at the beginning of its formation, stochastic processes dominated the human being, then with the development of society, spontaneous processes were moved to the periphery due to the conscious factor and social institutions. The bifurcation phases were overcome thanks to the victory of the techno-humanitarian balance and the awareness of the essence and causes of the problem.

Looking back and analyzing the essence of most anthropological crises, we can conclude that their nature lies in the underestimated degree of threat of consequences, or in misunderstanding the essence of the causes of technological take-off. The development of artificial intelligence will probably also foresee its active inclusion in the process of natural selection, in the struggle for energy, substance and information. And, in general, for everything that it considers a resource. To put it mildly, the fact that many researchers do not quite understand how the whole system works is causing concern. And in this context, it is clearly not enough to create a rational machine with a pure heart and good intentions, hoping for a successful outcome and a wonderful appearance of friendly artificial intelligence. And this is not the fault of specialists. The root of the problem is not the ignorance of specialists how to create a friendly thinking machine. The reason that can lead to the cessation of human life, at least in the forms familiar to us, may be the belief that artificial intelligence will be necessarily friendly. First of all, because development paths cannot be imposed on a complex system, non-linear environment, which is not inherent to it inherently. When dealing with the creation of consciousness in a machine, a person, as has already been said, does not understand how the whole system works, and therefore it knows that it is a fan of nonlinear vectors, attractors, to which artificial intelligence

will follow. But nevertheless, in his study, E. Yudkowski puts forward the thesis that the friendship of artificial intelligence can be based on the so-called utility function (a synthesis of values, preferences, wrapped up in the pleasure of achieving a goal, which is embedded in determining the benefits in algorithmic patterns (see: [6]) First of all, artificial intelligence should never be hostile or ambivalent with respect to the human species, for whatever purpose the machine does not try and no matter how many steps of self-improvement pass. this is impossible without a deep understanding of human nature by the machine (does the man himself understand it?), so as not to harm a person in the future even as a result of random, indirect consequences of his actions (as we have already mentioned in the context of understanding the three laws of A. Azimov). In doing so, we do not want to get an artificial intelligent agent who performs short-term tasks with the help of measures that would prove harmful to humanity afterwards. As an example of the implementation of unforeseen consequences, N. Bostrom writes about the so-called pernicious refusals (see: [1, p. 153–176]). Here we give some options for disastrous failure—vicious implementation and infrastructural redundancy. The first of the scenarios in which the artificial superintelligence reaches its goal in a way that is optimal from its point of view, but a controversial universal scale of values. For example, the desired result that I want to come to is a constant smile on my face; the way to achieve this goal in understanding the machine is to directly engage the nerve of the face, which will inevitably lead to paralysis of facial expressions, as a result of which the smile will not leave the face. The worst thing is that the choice of this method of implementation is not due in any way to the desire of the machine to harm a person. In this case, a vicious realization, manipulation on the facial nerve, is much more optimal for machine intelligence than the usual methods of man, due to the fact that this is the most complete way to achieve the ultimate goal. As a result, super-intellect transforms the available space and substance into staple factories. The absence of frozen dogmatic values is another essential, fundamentally important quality of friendly artificial intelligence. The axiological landmarks of machine consciousness must endure corresponding transformations in close correlation with changes in landmarks in society [7–21].

4 Results

The result of the evaluation was the consideration of a previously methodology for assessing the effectiveness of the development of artificial intelligence, and the presentation of the positive development effect was laid. However, a comparison of the benefits and costs in cash does not always allow us to correctly reflect the effectiveness of the introduction of artificial intelligence as a nonlinear development of the social system. In particular, technical (technological), social, economic, political, etc. goals often cannot be adequately represented in the methodology for developing implementation effectiveness, since all these goals can be represented in monetary

terms. The main target for the development of artificial intelligence is the desire to improve the social and information environment, to raise the level and improve the quality of technical services.

5 Conclusion

The system of values embedded in a friendly machine does not have to be defined once and for all. Such theoretical constructions look at least utopian. From the foregoing, it becomes clear that the topic of friendly artificial intelligence requires further specification and development, although its supporters think very optimistically. Today, science does not guarantee an unambiguous prospect of the concept of friendly arrogance in the language of mathematics, nor is there a guarantee that the creation of such a mind is generally possible or its real integration into the perspective architectures of computer consciousness. The mentioned organizations working on the creation of a human-level thinking machine include: AGIRI, CYC, Google, IBM (several projects), LIDA, Nell, Numenta, SNERG and Vicarious. There are also at least ten projects whose funding sources are not considered reliable: NARS, Novamente, Sentience, SOAR, and also DAPRA, which supports directly or through intermediaries projects related to the development of an artificial intelligent agent, as well as related technologies (see: [2, p. 36]). This is not a complete list. In the context of this, a quite logical conclusion arises: the probability that the first artificial intelligence will be released within legal projects in the MIIR laboratories is negligible, and, therefore, there is a rather meager possibility of introducing a module of friendliness into this cognitive architecture. Probably, the developers of the first intelligent machine will not care much about the problem of software friendliness. However, there are strategic vectors that may further contribute to blocking the enemy's arrogance. Today, there is an educational program for advanced universities and mathematical competitions, within which MIRI and CEAR organized the so-called "mind training camps." In these cells, potential creators of smart programs and managers are trained, who shape further technical policy, innovative thinking. In the long run, this should help to avoid developmental deadlocks and pitfalls on the path of improving the created mind. It is clear that these measures are not enough, but MIRI and CEAR managed to draw the attention of the public to an important risk factor, due to which more and more works are devoted to the problem of singularity, the authors of which in this way expand and deepen the scientific and philosophical aspects of the phenomenon of artificial intelligence risks.

From Artificial Intelligence to Dissipative Sociotechnical Rationality: Cyberphysical and Sociocultural Matrices of the Digital Age

Sergey V. Leshchev

1 Introduction

Artificial-intelligence and converging technologies [23] currently setting global post-industrial (economic, cultural, social, and manufacturing) trends, such as the Internet of things, penetrating computing, physical-digital communication, smart medicine and smart education replacing step by step the traditional forms of communications, logistics, management, data logging, and automation. Reproducing the ever-expanding pool of the knowledge-based economy, AI becomes the driver of the "third wave" (E. Toffler) and has impact both on the macroeconomic situation and the microeconomic trend of agent involvement in decision-making and procedural regulation of business arrangement and conclusion of transactions, since these processes and procedures are more and more mediated by machine learning algorithms and neural network application agents. From the transhumanist view, merging macro- and microeconomic trends presupposes a gradual integration of global computing socio-technical platforms (management frameworks, electronic governments, and electronic exchanges, ERP-systems, Industry 4.0, etc.) and distributed AI systems involved in local-transaction decision-making.

2 Methodology

Determining the infogenesis and infotectonics of the current communication image of the digital world [18], modern Sociotechnical systems regard the relationship between intelligence, rationality, and intersubjectivity in a new way. The research

path becomes complicated and determined by the environmental growth of intelligence, for example, thanks to AmI and AmE technologies [6, 7], which combine the concepts of distributed AI and sociotechnical autonomous technology-production platforms. The programmability of technical evolution directs the local AI to the sociotechnical framework of machine intelligence. Technically (from the perspective of big data technologies, distributed systems, and cloud computing), this means that the development of artificial intelligence is more and more hard to keep within the local framework. This point, in particular, has been a trigger mechanism to launch the friendly AI initiative ("Open Artificial Intelligence"), which involves the development of a state/corporate-free AI platform.

AI as a factor with transformative potential for the development of the super-industrial economic image of the digital world deal with various contra- and co-directional constituents of the sociocultural, techno-scientific, and managerial system of our time. The modern economy orients towards the randomness of changing management factors, the virtualization of physical-economic platforms, the geopolitical plans of action of transnational corporations, the strategic intuition of business leaders, which also establishes the general methodological eclecticism in the enterprise performance. Economic structures suffer from both an administrative deficit and the pressure of a non-economic corporate paradigm. The "strategy of new instrumental rationality" of industrial communication poses the problem of choosing the appropriate management methodology. For example, business intelligence systems will slowly shift to big data.

ERP and quality management systems, ISO standards, LEAN-production systems define the methodological interface of the economy. But without measures on the reduction of communication entropy, they cannot have a substantial impact on the main economic criterion (ROI—return on investment ratio). It is in this sense, artificial intelligence technologies are remodeling the methodological communication core of engineering, industrial, and production practices within the Industry 4.0. technological concept. Since artificial-intelligence initiatives are capturing new communication markets, any kind of private unit of the technological sector is necessarily connected with social dimensions. Thus, ideas on the sociotechnical, cyber-physical, media-cultural, and transdisciplinary landscapes of the digital era are generated, which change the conventional scientific and philosophical milestones of analytics. In this sense, this study can be methodologically defined as an environmental analysis umwelt analysis of socio-technical systems of the artificial-intelligence era.

3 Findings

In the digital age of the information society, understood as the information age [3], the changes occur in ideas on computing as it is (AI, big data, cloud computing, fog computing, data lakes, machine and deep learning, evolutionary/genetic algorithms, fuzzy logic, neural networks, computational chemistry, bioinformatics, quantum and molecular computers, neuromorphic chips, memristors), as well as

on interdisciplinary correlations of nano-bio-info-cogno-socio-humanitarian dimension of individual, economic, and technological reality [8, 9, 15–17]. Cyberphysical media, physical-digital sociality, computer visualization, genetic sequencing, CRISP methodology, chemical informatics, molecular computing, artificial-intelligence assistants make it possible to frame a new concept of "computer naturality" of the post-information society.

A complex ecology with the interface mediating communication between various communication systems and levels emerges. In the post-digital era, communication mediums and interaction interfaces [14, 19] become the key players in communication markets, while entities, actors, agents, objects recede into the background.

The convergence of philosophical and ICT slang may seem inefficient, in so far as the problem of interfaces is regarded to a large extent from the technological point of view. Nevertheless, such a transformation gets special importance in the light of the formal-substantive and procedural adaptation of the philosophical opposition of "essence/existence" to the landmark sociological and theoretical-systemic statements "The medium is the message" (M. McLuhan) and "Only communication can communicate" (N. Luhmann). The substantive economic, social, and cultural side is projected onto the median register of mediation accepted in one or another social matrix; for example, the medium interface in economics is finance (moreover, the level of their mediatization is even more significant: according to H. Lumanu's opinion, money is "generalized media"). The primacy of mediation is enhanced by the theoretical and systemic extension of the thesis that humans cannot communicate; not even their brains can communicate; not even their conscious minds can communicate. Only communication can communicate" [20, p. 169]. Users become secondary to social networks, scripts, protocols, and other digital discourses; drifting from subject-subject interaction patterns (meeting, chat) through subject-object ones (neural interfaces, man-computer) intersubjectivity recedes into the shadow of inter-objectivity (B. Latour) to object-object interactions (machine-to-machine, AI, Internet of Things) interactions. Complex forms of intermediate subject-object coherence, quasi-objects and quasi-subjects [24], and the corresponding socio-semiotic grounds of communication between objective and subjective worlds that deliver pre-information meta-symbolic networks of meaning coherence emerge. The socio-semiotic view of "things" in their symbolic (and today in information and post-information) representation sets the techno-existential arrangement (M. Heidegger) of current hybrid meta-sociality, landscape of the emerging cyber-physical world, which keeps the information and communication reference of networks and actors (in terms of B. Latour's actor-network theory [12]), semantic and semantic conveyance agents, restoring pools of possible meanings for opposite players (quasi-thing and quasi-I). M. Serr represents in details his vision of the "quasi-texture" of the objective and subjective worlds (long before the informational description of the subject/player of distinctions) that is based on the involvement of actors in the interdependent game of references: "This quasi-object is not an object, but it is one nevertheless since it is not a subject since it is in the world; it is also a quasi-subject since it marks or designates a subject who, without it, would not be a subject (…) This quasi-object

that is a marker of the subject is an astonishing constructer of intersubjectivity. We know, through it, how and when we are subjects and when and how we are no longer subjects (…) The "I" in the game is a token exchanged." [24, pp. 225–227].

Other sections of sociality in B. Latour's sociology and E. Cassirer's "Philosophy of Symbolic Forms" and J. Spencer Brown's (mathematician and logician) "Laws of Form" that are more abstract, but no less important for the theory of post-information development of subjective ontological studies are conceived in a similar way. The fundamental quasi-dimensionality of worlds that decay on both sides of the borderline of objectivity, reality, differences in the information era emerging decade after decade has become more fragmented.

Being a distinctive marker of virtual worlds from an ontological point of view, AI predetermines a different, hyper-simulative order of "erecting a tower of values" of cyber-physical, augmented, virtual dimensionalities. This order establishes the need for the materialization of its essences following meta-discourses such as codes, protocols, specifications, scripts, ontology languages. In the real world, these are a legal or economic-political codification of actions, prohibitions, publicity. However, virtualization is coming. Anthropogenetic grounds are replaced by info genetic symbolism, thereby changing the information path of autopoietic communication (F. Maturana, N. Luman). The information following technological multi-layerness and panoramic virtualized representation in electronic culture generates itself. In this vein, AI transforms the available innovative communication capabilities and respective economic, regulatory, cultural, and social patterns.

Surely, at the dawn of the post-information era, it is hard to estimate the scale of the upcoming techno-social drift and technocenoses from NBICS-transformation. In the perspective of singularity (described by futurologists [1, 4, 11, 25] or neural net (web 4.0) we can expect inverse attribution. It is economics, culture, sociality, and the administration that become attributes of superintelligence [2], but not the latter—turn into their entelechy. M. Castells says his contr/pro-argument that mitigates this opinion: "… methodological choice does not imply that (…) technology (…) determine society. (…) the dilemma of technological determinism is probably a false problem, since technology is society, and society cannot be understood or represented without its technological tools." [3, p. 5]. Being focused on the last statement "society cannot be understood or represented without its technological tools", can give examples of these tools developed by Russian researchers in the field of hierarchical management of economic entities [21, 22].

Electronic culture, environmental awareness (smart environment, ubiquitous computing, cyber reality, RFID-tags (Radio Frequency Identification) and NBICS technologies (Convergent Nano-, Bio-, Info-, Cognitive, and Socio-Humanistic Studies and Technologies) that offer diverse intelligent systems of information processing, reveal the establishment of a new cognitive ecology of social space, new forms of environmental man-technology unity [5, 14, 19], thereby absorbing sociality and predetermining its previously not represented forms in cyber terms. Cognitivity takes on new dimensions and existential forms. Neurocomputer interfaces, hippocampal prosthetic devices, neural assistants, cybernetic organisms, neural networks, robotic systems, artificial-intelligence agents and big data systems that

initially arranged the infrastructural needs of the information and communication complex are slowly transforming the natural and social worlds in a globally growing dialectic of noospheric emphasis of the knowledge-based economy, artificial-intelligence ontology, technocenoses of the digital area. Examples of ontological constituents are virtual ontologies of computer games and 3D-printing technology converted into a smart measurement of an increasing number of micro-, meso- and macro-industrial enterprises. Globalization super-industrial (E. Toffler) processes getting more intense through ever-deeper info- and nano-technological penetration into reality, diverse forms of the computing industry and groundbreaking information and communication solutions, allow talking about modern social, cultural, techno-scientific realities in terms of multi-dimensional communication mediatization. Interactive interfaces with sometimes synergy-homogeneous points of diametrically opposed areas of development and spiritual fields (generalizing the logic of the communicative action of J. Habermas) become the primary morphological pattern of any (techno-scientific, socio-political, neuro-computer) communication [13]. First of all, the groundbreaking socio-ontological platform that affects all areas of sociality Industry 4.0 (German initiative) or its Dutch analog Smart Factory worth to be mentioned.

The strongest integration of opposite economic, sociocultural, and epistemological trends and practices in Industry 4.0 (subject and object, supply and demand, creativity and computing) gives a right to talk about bidirectional flows of rationality, from and towards subject-object opposition in the new fundamental laws of cyber physics, hybrid ecosystems of inter-subject-objectivity: from an AI application to the user, cloud platform, flexible assembly-line production, consumerism, fashion, and cultural laws and vice versa. Up-down and down-up methodologies, heterarchical and hierarchical taxonomic forms, ordered and chaotic dynamic trends are losing their certainty in the complex techno-social measurement. In this regard, instrumental (J. Habermas), limited (H. Simon) rationality is missing the essence of the familiar objective world and practical formulas of its applicability. This does not mean that rationality completely fades in new cyber-physical umwelt-matrices (augmented reality, virtual reality) and the virtual ontology of society gets out-of-rational (unsmart). On the contrary, rationality finds itself in a balanced sociotechnical model, thereby restoring stagnant robotic, mechanistic, artificially intelligent matter and giving it the portion of rationality and techno-psychic activation. It makes sense to designate such rationality as dissipative. The virtualized ontology of society is occupying new socio-psychic regions of the interface-mediated inter-subjective and inter-objective being of quasi-objects and quasi-subjects. This is meso-being (being of the middle world), i.e. socio-cultural, economic, and techno-social bridge from the microcosm of matter to the macrocosm of hyper-social superintelligence.

The “limited rationality” of penetrating computing systems, cognitive intelligence, and the Internet of Things are sinking today in the ocean of universal self-referential cyber-physical coherence that transforms the artificial-intelligent-vital, carbon-silicon constituents of soft-hard-wetware communication systems into ontological coherent metacommunication of the natural and artificial (everyware [10]). All real things become digital rational, and outdated metaphysical frameworks of

rationality and intersubjective interfaces are no longer able to set the scope of such complex rationality. Both artificial reality, nanotechnologically induced by the engineering of interatomic relations, and the correlative causality occurring in big data systems from unstructured data, and biologically newly born synthetic bacterium breed at the Craig Venter Institute in 2010, and AI systems cannot be longer regarded as accompanying artificial forms of nature. The naturality of simulacra gets more engaging than reality.

Thus, the focus of opposing the natural to the artificial is shifting. New artificiality implies the dissipation of rationality in communication media, i.e. divergence of the cognitive-rational image of the digital era. Innovative reengineering of industry and management, education and computing, is based on dissipative rationality that involves a complex game of a techno-scientific combination of competencies, knowledge, skills, and abilities. It is more correct to designate cyber-physical, real-virtual ontologies, and media as complex rationality ecosystems dispersing techno-scientific communication.

4 Conclusion

Regardless of the specific dynamic trends of the historical context and the priority origin of some technologies, today it can be argued that AI technological initiatives are introduced under global NBICS transformations of culture and society, technology and science, business and production. The idea of such changes comes down to the creation of a newly ontological socio-technical framework for all communication practices of social self-fulfillment with differentiated techno-social dimensions. Metaphorical traces of postmodern thinking are manifested more and more in the techno-scientific matrices of social relations. The “Society of Society” (N. Luman) is turning into a totally communicative mediator of numerous forms of mediatization and penetrating computing technologies not only in the theoretically systemic, and methodological but also in technological respect. The decentralization of power and management chains is arranged by the dissipative rationality of making decisions at the level of network topologies of distributed computing networks and artificially-intelligent agent modules. The rationalizing environment makes a cyber-physical uplift of urban landscapes to intelligent ecosystems and post-industrial info-material production platforms like Smart Factory and Industry 4.0. At the same time, NBIC reconstruction and support of socio-technical homeostasis (cyber-physical systems, hybrid process media, electronic governments, smart logistics, smart cities, blockchain, cryptocurrencies, data centers, supercomputer processing systems, Internet of Things, bio identification, RFID-tags, physical sensor networks, geo-targeting and geo-tracking, exoskeletons, neural interfaces, augmented and virtual reality, gamification of processes, cognitive prosthetic rehabilitation, genetic mapping, nano-pharmaceuticals, machine learning) and NBICS regulation of techno-scientific and socio-cultural development (ecosystem thinking,

transhumanistic vision, legal support of AI-solutions, techno-evolutionary transformations of symbolic consumption and cultural codes, development of mixed reality ontologies, new cognitive matrices, neural philosophy, quasi-object cultural and natural frontier) seem to be the main trends of survival in IA landscapes. Observations of ongoing projects and neural network technologies of 2015–2019 show that AI has not yet grown for natural-calculable laws like Moore's or Handy's law, despite obvious exponential growth. Each subsequent ICT and the neuro-cognitive obstacle is overcome by, for example, the unpredictable discovery of groundbreaking architecture of the neural network. Nevertheless, machine learning representing a highly specialized law of artificial intelligence is capturing the market everywhere and is able to make lifting the rules and regulations that hinder the existential risks of AI technologies legal.

State Regulation of Blockchain Technology in the Sphere of Payments and Financial Services

Vera D. Nikiforova and Alexander A. Nikiforov

Abstract *Purpose*: The purpose of the chapter is to conduct the comparative analysis of the results of the use of cryptocurrencies based on blockchain technology in Russia and abroad; to develop recommendations for creating an effective system of public administration in Russia in connection with the widespread introduction of blockchain technology in the field of payments and financial services. *Design/methodology/approach*: The authors identify two areas of state economic regulation: the formation of the legal framework that provides a balance between traditional values and new technological approaches; stimulating existing trends or restraining them based on the objectives of ensuring economic growth and reducing socio-economic risks. *Findings*: It is shown that the modern system of state regulation of information technologies in the financial market needs to be improved in such areas as creating more favorable conditions for competition and protection of investors' rights, as well as preventing money laundering and fraud in the field of payments and financial services. *Originality/value*: A promising approach to solving this problem is usage of the developed measures to change the legislation in the field of FINTECH regulation based on the use of blockchain technology. The proposed measures reflect the conditions under which digitalization processes, including digital business, in payments and financial services should be encouraged or restrained in Russia.

1 Introduction

The world financial crisis of 2008 acted as a catalyst for the invention of blockchain, a system of decentralized data exchange, and the formation of a distributed secured ledger. Initially a part of the bitcoin algorithm, blockchain technology started to develop rapidly, bringing forward new digital currencies (Ripple, Ethereum, DASH, and more) and smart contracts. The attitude of government institutions and banks towards such cryptocurrencies varies.

Countries have different approaches to recognizing the cryptocurrency as a legal tender at the state and corporate levels. Japan has legalized cryptocurrencies and developed a regulatory and legal framework to introduce them in the economy. The USA has recognized the bitcoin as one of the official financial tools, but has not recognized it as a currency. In the UK bitcoins are considered private funds. In China cryptocurrencies are prohibited for government-owned companies and banks, but allowed for individuals. In Europe, bitcoins are recognized as securities, while in Russia, cryptocurrencies have the status of either a digital commodity or an asset.

Regulators recognize the progressiveness of blockchain technology and fear that this technology could, on the one hand, lead to tax evasion, while on the other hand, to cashing out shadow funds and financing terrorism. In our opinion, a consensus has yet to be reached in the scientific community regarding the use of cryptocurrencies based on blockchain technology. The VI International Legal Forum, which took place in Saint Petersburg in 2017, gave special attention to the legal relations which arise in a digital environment and to the need for applying legal instruments in communication technologies.

2 Materials and Method

The ongoing processes of digitalization in the field of money, Finance and banks are considered in the works of many researchers: Pryanikov et al. [1], Strembitskaya et al. [2], Kochergin [3], Swan [4], Kornilov et al. [5]. They are aimed primarily at identifying the advantages of information technologies compared to traditional technologies, as well as determining the areas of their distribution in the economy. Separate studies are devoted to legal issues of using blockchain technology: Bulgakov [6], Savelyev [3], etc.

Despite the high level of study of the problem requires a comprehensive and systematic approach to the assessment of structural civilizational changes in economic systems in Russia and abroad, the consideration of blockchain technology as an institutional technology that is based on algorithmic trust, the formation of new civil society and collective entities.

Further scientific discussion and theoretical developments on the formation of the legal field and the recognition of cryptocurrency at the state level, as well as the creation of a system of state regulation are necessary. The short-lived experience of

a number of countries that have officially allowed the exchange and trade of cryptocurrencies (Singapore, Switzerland, etc.), as well as countries that have recognized bitcoin as a means of payment (Japan, South Korea), and countries where cryptocurrency is prohibited for legal entities, but allowed for individuals (China), etc. It is necessary to find a balance between traditional values and new technical opportunities that blockchain technology opens up in the sphere of making payments and providing financial services.

There are two areas of state regulation of the use of blockchain technology in Russia, which require high flexibility in the context of globalization and integration of the country into the world economy:

- formation of a legal framework that provides a balance between traditional values and new technological approaches;
- stimulation of existing trends or their containment based on the objectives of ensuring economic growth and reducing socio-economic risks.

High flexibility of state regulation of digitalization processes in financial markets in these areas should be provided by systematic monitoring of trends in these areas and implementation of incentive or deterrence measures, depending on the identified trends and current opportunities and needs.

3 Results

The evolution of money from a commodity item to an electronic one has allowed for an understanding of the essential nature of money as a carrier of economic price information, a carrier which can appear in material or non-material form. New information technologies in the field of payment and accounting are now becoming an important tool in the competition between large and small banks and between banks and other financial institutions. Remote banking, electronic receipts, electronic money wiring, and so on, have become a method of payment, based on transferring electromagnetically stored information [3]. Technically speaking, electronic payments can be carried out without the involvement of banks; they are transforming the payment system, turning it into a polycentric one. A certain period of time was needed for members of society to become used to these transactions, to increase their trust in the electronic money issuers and systems, and for this money to be recognized as legal tender at the national level.

Globalization and the development of digital technology are creating the prerequisites necessary to form a qualitatively new information environment capable of real-time money transfers and accounting on a global scale, as well as one capable of influencing the events and actions that take place on the planet and of determining the vector development of a new “financial civilization”. As is known, blockchain technology, as an innovation in the area of information services, can be spread on the mega and macro economic levels by creating a corresponding digital ecosystem and

can also be applied in many different types of economic activity and in the divisions of big business through the creation of private blockchain networks [4].

The need for shared data necessitates the use of a distributed database, which provides, along with storage, the ability to carry out data management functions in certain nodes of the network, as well as the exchange of data between them using query execution. It is especially worth noting here the significance of the software based on which information management technology is applied in the field of finance [7, 8].

The appearance of blockchain technology in accounting and payment has a significant impact on the whole architecture of emerging relations in the financial services market. This technology, which is based on the decentralized storage of databases and the multi-level cryptographic coding system, ensures the reliable accounting of cash equivalents. Bitcoin, as a cryptocurrency for monetary payments, firstly becomes information about its usefulness for transaction participants and society, information created by its proprietor; secondly, information, which is certified by the blockchain technology system as a public institution; thirdly, information, used by participants to measure their merits to other participants and the society.

In our opinion, the widespread introduction of blockchain technology into the traditional banking system, where the majority of accounting and payments are performed, is not very likely or effective due to a number of circumstances. First of all, it is due to the function of money in the banking system, which is based not on exchange, but instead on its nature of credit. This makes the transition to transactions based on universal exchange products more difficult. Secondly, it is due to the fragmented standardization of the banking system, which has yet to take on a global character. Third of all, it is related to the fact that the activities of the traditional banking system are based on support from the government, guarantees of deposit insurance, reversibility of operations, authentication of documents, and so forth, which is not offered by blockchain technology. Finally, smart contracts, as a software for legal transaction agreements, do not fit into existing banking regulation.

Along with this, it seems premature to consider cryptocurrency money just yet. There needs to be an accumulation and summary of the experience in countries where cryptocurrencies have been completely legalized (Japan and others). One problem that remains is the use of cryptocurrencies as a means of providing economic growth that satisfies domestic investment demands instead of as a speculative financial tool. There are ongoing heated debates about recognizing cryptocurrencies as property and creating the appropriate regulation for it. A more pragmatic approach may be defining cryptocurrencies as material property instead of fiat money or securities.

At the same time, it is worth noting that the modern banking system in Russia experiences serious problems with interbank settlements during periods of crisis and needs to adopt blockchain technology. This will ensure information transparency regarding money transfers performed between banks, allowing the Central Bank, as the mega-regulator, to track all interbank and other money transfers in the banking sphere, while commercial banks will only track the money transfers of their clients, and the clients will only track their own payments. In 2016, more than 10 of the largest Russian banks, along with Qiwi and the Bank of Russia, were involved in

the development of a technological platform based on the Ethereum code (with their own genesis block). The consortium "Fintech" was established to create blockchain technology prototypes and to develop a software complex, which would provide the storage and exchange of financial information by applying distributed ledger technology. Practice shows that blockchain technologies are profitable for dependable banks which hope to get away from intermediaries in the paperwork, optimize costs, and prevent the loss of clients. Certain prospects are opening up to banks by adopting this technology in factoring (trade financing), in payment of services provided using letters of credit (based on the application of smart contracts), bank reporting, receiving reports from their clients, and so on.

New financial institutes based on blockchain can be expected to appear, along with the adoption of blockchain technology in both the banking area as well as other areas of financial services, where transaction costs are high and a lot of time is spent on payment negotiation and settlement. More than anything, this concerns the organization of direct peer financing, crowdfunding, the processing and sharing of financial information in auditing and accounting, the handling of securities in custody accounts, the accounting and re-accounting of rights to securities, and also other specific businesses. Therefore, the standardization of blockchain should record the main economic factors of its commercialization.

The information support of scientific research in the Russian economy, including research on the priorities of innovative companies and methods of decision support in the IT market, can also rely on using distributed ledger technology [9–11].

Nowadays, blockchain technology is being used to solve certain management problems in the formation of real estate registries (Leningrad Oblast). The Rosreestr (the Russian federal service for state registration) and oracles, which input external data, fix the contract in blockchain, while a smart contract is signed between the interest holder and the developer. This contract contains the amount of the developer's insurance premium and the amount of the interest holder's advance payment on the real estate project to the protection fund, as well as the completion date of construction. Each of the parties forms their own node. When the completion date arrives, the program code is sent to the oracles to receive information on the readiness of the property. The blockchain network either automatically transfers the money from the protective fund account to the interest-holder's account if the entry into service of the property has passed the deadlines, or it makes a payment to the developer's account if the construction is finished on time. However, in order to make money payments, the cryptocurrency needs to be tied to the rouble, which is accomplished using the blockchain token. In this way, the double sale of an apartment and the risk of financial fraud are avoided.

A discussion is currently taking place in Russia on whether legislative provisions for the legal regulation of blockchain technology need to be developed. Some experts believe that in order for this technology to be used in the area of cryptocurrency trade there needs to be a special law and legal status given to these currencies. On the other hand, according to a number of experts, there is no need to develop legislative provisions for regulating blockchain technology, seeing as the products created

with this technology and which represent information systems are already regulated by existing laws in the country regarding information, information technology, and information security. Along with the legislative regulation, the development of an industry standard of blockchain technology is being proposed, which can have mandatory application in areas such as state defense orders, use of atomic energy, and use of other information containing government, bank, and business secrets, as well as personal data. For information of limited access, legal risks arise in connection to the application of blockchain technology in products that allow the open distribution of information. These risks are generally due to the inability to determine the person responsible for spreading the information: the miner, agreement manager, or another person involved in the transaction [12].

Another important part of this discussion, in our opinion, is finding out whether or not products created using blockchain technology are legally valid. If we look at the Russian legal proceedings, then we see that hash codes, which represent records in the blockchain, electronic documents, electronic signatures (simple, reinforced unqualified, and qualified) are recognized as admissible for proving legal facts. As far as smart contracts on blockchain platforms that are used in other fields besides payments and financial services, it is necessary to first and foremost ensure their consistency with the current laws in order to solve the issue of legalizing such contracts. This is the direction American lawmakers are headed in. In particular, the condition of such recognition is included in bills that recognize the legality of blockchain technology and smart contracts in a number of US states (Florida, Arizona). This does not contradict already existing laws and regulations.

Considering all the various approaches to legalizing cryptocurrencies in different countries around the world, an interdepartmental group at the State Duma, jointly with the Russian Ministry of Finance and the Central Bank of Russia, have laid the basis in Russia for the current efforts to draft bills to determine the status of cryptocurrency mining, licensing the use of cryptocurrencies for legal entities, using cryptocurrency crowdfunding, taxing operations of cryptocurrency, and so on [5]. The creation of a regulated environment for digital business offers a solution to a number of accompanying issues related to countering the laundering of criminal money and financing terrorism, fighting internet fraud, etc. At the legislative level, the most reasonable options seem to be to place cryptocurrencies at the same level as either federal loan bonds (suggested by the Russian Ministry of Finance), or money surrogates (suggested by the Central Bank of Russia). Whereby, using cryptocurrencies as a financial asset will not become publicly available to individuals and will be offered only between members of the regulated exchange. Therefore, they envisage the creation of a closed regulated environment of cryptocurrency trade, which is not intended for accounting, but instead for exchanging to a national or international currency.

By viewing this as a transitional step in the process of legalizing the use of cryptocurrency based on blockchain technology, we believe that it is dictated by the social economic situation that has developed in the country, and yet, this step is aimed at creating the continued development of the digital economy in Russia. In our opinion, it would be expedient for Russia to create science parks or clusters, introducing a

decentralized system for organizing the circulation of crypto assets. In this case, legal risks related to the use of crypto assets are localized and companies will be the ones to carry the main legal burden. This would primarily be the exchanges and technological firms that deal with the equipment, programs, and services necessary for connecting and sharing information.

4 Conclusion

The prospects of using blockchain technology in the area of payment and finances in Russia are largely relevant for the banking and insurance sectors and are significant for accessing information on money transfers between banks, the truth on reporting data, the authenticity and reliability of clients for potential users, as well as for mechanisms of assessing the solvency of clients, financing trade, settling claims, using open licenses, and more. Whereby, the need to establish new ways of using information obtained by applying the new technology and the features of the technological process in making payments and providing financial services at the legislative level is not excluded.

Among the remaining problems with using blockchain technology is the issue of guarding the rights of those who use products created with this technology, seeing as the system is not always able to automatically ensure the necessary protection of rights. An optimal solution to reducing the legal risks in the area of cryptocurrency application would be the creation of a closed cluster environment for operating digital business while taking into account the peculiarities of the social and economic condition of the Russian economy. At the same time, a number of problems relating to the prevention of financial fraud in the area of internet payments, countering the laundering of criminal money and financing terrorism using crypto assets are solved. Closed blockchains can be applied in situations where the information being exchanged contains government, bank, or business secrets.

Open blockchains can already be developed today in the field of processing and sharing financial information, in auditing and accounting, handling securities in custody accounts, accounting and re-accounting of rights to securities, in creating real estate registries, as well as in other specific businesses. In the future, a wide range of applications of open blockchains in the Russian economy will open up in the organization of direct peer financing, lending and insurance, and crowdfunding. In this case, ensuring information security and reducing legal risks is possible by using integrated mining technologies which allow the same equipment to be used and thereby increase the security of more than one blockchain.

Furthermore, using blockchain technology for making payments and providing financial services will allow for the elimination of unjustified mediation, reduced prices in banking, insurance, and other commercial businesses, which will meet the marks of modern technical and technological support, security, decentralization, and different levels of accessibility. It will provide a greater involvement of savings in financing investment projects that are based on advanced algorithms and process large

data while assessing the risks in each specific case. Objective: to identify economic and legal models for the Russian Federation to transfer to digital economy so as to expand the capacities of blockchain technology in the payment system, bank sphere, activities of financial institutions, formation of real estate registers and other spheres of the economy.

Acknowledgements The chapter was prepared in the framework of fundamental research on the University-wide complex theme of the Financial University (Moscow) "New paradigm of social development in the digital economy", the sub-theme of the study "Theory of money and the development of the financial market" (2019–2020).

Ontology of Artificial Intelligence: On the Question of the Dehumanization of Social Regulators

Anna V. Popova, Irina V. Balashkina, Pavel V. Nikitin, and Galina A. Prokopovich

Abstract *Objective*: the purpose of this chapter is to analyze ontological approaches to the study of artificial intelligence. Legal ontology of this issue is mandatory for the implementation of the national program of development of artificial intelligence, its legal regulation in order to define artificial intelligence as quasi-objects of law, and robots and objects of robotics—as objects of legal relations. *Design/methodology/approach*: the article considers approaches to determining the essential features of artificial intelligence, its fundamental differences from other robots and objects of robotics, which is necessary for the most effective implementation of the provisions of the National strategy for the development of artificial intelligence until 2030. The methodology of the Chapter consists in the use of methods of interpretation of legal documents and formal and logical tools not only in the system, but also in the comparative legal analysis of existing strategic and regulatory legal acts of foreign States that determine their policy in this area. *Conclusions*: it is concluded that there is a need for new approaches to determine the place and role of various objects of robotics, neural systems, artificial intelligence in the system of law and the system of legislation and the possibility of defining artificial intelligence as a quasi-object of law. *Originality/value*: the solution of these tasks, according to the authors, will contribute to strengthening the digital security of the individual, society and the state; creating economic conditions for the development and implementation

1 Introduction

Ontology is a part of a person's worldview, his subjective idea of objective reality as a single holistic universe. Being a part of philosophical knowledge about the surrounding reality (being), ontology as its subject can have absolutely any phenomenon of the material and ideal world. As you know, ontology originated in the era of Antiquity and included the "doctrine of being," although the term "ontology" was not put into scientific circulation until the seventh century, when the development of science, the emergence of new directions and, as a result, development technologies required scientific understanding and explanation.

In the eighteenth and nineteenth centuries, not only material objects, but also such ideal constructions as the state, law, consciousness, culture, and other social institutions began to be viewed from ontological positions. As a result, already in the twentieth century. the ontology of law, the ontology of consciousness, the ontology of informatics, the ontology of artifacts, the ontology of digital models, the ontology of virtual reality, etc. how much he is trying to prognostically determine the future directions of its development, both in material and ideal form.

2 Materials and Method

The scientific literature substantiates the opinion that "ontologies are, first of all, extremely general and, preferably, logically correct, the image of the subject area of interest, serve for general orientation, define the structure of the picture of the world in one or another part of it" [10] The emergence of electronic-virtual reality as a fundamentally "new type of artificially created virtual reality" [13] in the second half of the twentieth century. becomes the subject of comprehension of a large number of ontological studies. As T. Sterledeva notes, ontology begins to change its meaningful meaning and embodies, in relation to its new object, "a certain type of vision of being (…) and a theoretical model of such a vision" [13], the distinguishing features of which are:

1. The definition of electronic-virtual reality as a special type of reality created by human (natural) intelligence for a person, in contrast to the material reality

created by Nature (God, Absolute Idea, Universe, Cosmos) for all earthly creatures without exception. Ideal reality is recognized, for the most part, as a product of the consciousness of only a person who creates his own artificial world, including in cyberspace [11].

2. Existing until the second half of the twentieth century. the ontological knowledge of reality surrounding the person (the natural world) consisted in the study and understanding of phenomena created and controlled only by Nature, regardless of the will and desires of the human society (collective consciousness) and each individual person (individual consciousness) of fires, floods, volcanic eruptions, earthquakes, epidemics of diseases, etc.). The ontology of virtual (hybrid) reality is not only dependent on a person, but also controlled by him, it is directly oriented to his interests and needs, including in the consumer material sphere.
3. In the material world there is only three-dimensional space (length, width and height), while in cyberspace the number of dimensions of the created space is infinite and depends only on the power of the corresponding computer (cyber-physical system, neural network, artificial intelligence) and the desires of the person himself in order to achieve their greatest comfort in a certain period of time.
4. The ontology of the natural world is based on the interpretation of temporality as the only possible measurement—the present and future course of events, while moving backward into the past is impossible. In electronic-virtual reality, the flow of time can be different, because there is the possibility of modeling the type of time with predetermined characteristics [13].

Modern man simultaneously exists in at least two forms—as a real material object endowed with consciousness in the natural (real) world, and as an avatar, a virtual (electronic) personality with the ability to choose appearance, age, and opportunities in the circumstances created by him life) in cyberspace created exclusively by the consciousness of the individual, based on his own desires and preferences, but always with the help of artificial intelligence, with which various technologies can be endowed biological objects. Such a parallel being of the individual, the coexistence of natural and artificial types of intelligence, of course, needs to be understood and further legal regulation in order to protect the interests of both the individual and society as a whole. Therefore, at the present stage of the development of information technologies, the ontology of artificial intelligence is of particular importance as a separate area of interdisciplinary research, which is a wide area of scientific research, including a complex of computer sciences, on the basis of which information, including nano-bio-info-congo (NBIC) technologies, are created.

Of fundamental importance in this regard are the study of the very possibility of cognition, its mechanism in relation to artificial intelligence, its correlation with natural intelligence, understanding of the nature and place of intellectual artifacts in the world, their inclusion in the sphere of social relations, their legal regulation. The solution to all these problems depends on the answer to the main question: do modern technological artifacts (cyberphysical systems, robots, robotics objects, neural networks) have consciousness and the ability to think, similar to a person's

natural intelligence. In modern scientific literature, in most works on artificial intelligence, the main questions are posed—how does consciousness and intelligence correlate? What organ in the biological body produces consciousness? Is consciousness possible outside of man? Is it possible to create artificial intelligence in complete identity with the human?

3 Results

The development of neuroscience in the middle of the twentieth century. allowed creating fundamentally new paradigms in the study of consciousness, one of which justified the need for a functional approach to the definition of intelligence, which was understood as a special ability of consciousness. In accordance with the functional theory of consciousness, neurons are able to imitate not only specific actions of a person, but even an individual or collective phenomenal subjective experience.

However, human behavior is not always exclusively rational in nature, often a person commits actions, obeying impulse, strong emotions, repairing certain negative qualities—cruelty, envy, insidiousness, anger, greed, etc. Therefore, in contrast to functional theory, at the end of the twentieth century. another paradigm of biological naturalism appears, treating human consciousness exclusively as a certain stage in the evolutionary development of an individual in society, due to which intelligence cannot be reduced solely to the properties of brain neurons.

The term "artificial intellect" and its main tasks, which are the analysis of the mechanism of human thinking and the creation on this basis of an electronic machine that can simulate the thought process for the development of a new branch of science, the purpose of which was proclaimed the modeling of human intellectual activity, were formulated in 1950s In the XXI century. in the field of artificial intelligence "fundamental research is developing, a new programming technology, a new architecture of technical means are emerging, and all this is used to create application systems designed to work in a wide variety of fields" [9].

By analogy with the interpretation of man as a biosocial being, in which consciousness (ideal) and body (material) is an inextricable dichotomy, in science and practice attempts are being made to create a single virtual "person" (intellectual system) in which artificial intelligence will be placed in the body a robot or a separate object of robotics. Defining artificial intelligence as digital intelligence, N. Bostrom distinguishes its following advantages, in comparison with natural (biological) human intelligence:

1. *The speed of the computing elements* of modern microprocessors is about 2 GHz, while the peak speed of biological neurons is only 200 Hz;
2. *The speed of internal communications* in the human brain (approximately 120 m/s), while in neural networks, information is transmitted at the speed of light (300,000,000 m/s);

3. *The memory capacity* of an average person consists of four to five blocks of information at a time, while the working memory of digital intelligence is much larger.
4. *Reliability, life expectancy, sensors and more* [2].

The development of artificial intelligence poses the following questions to humanity, the answers to which are debatable. As a result of the development of information technologies, will the human component of the world of people—humanity, real interaction between people—be diminished, inadvertently or on purpose, by the humanitarian component? Can a neurocomputer interface contribute to human happiness in a philosophical and ethical sense? What will be the impact of nanotechnology on the institutions of power, the ecological system and other spheres of life of the individual and society? How will powers be divided between man and artificial intelligence, who will protect people from illegal actions of information artifacts and in what ways? Could artificial intelligence incite the transfer of human thoughts to outsourcing? Who will depend on whom: are we from cyberphysical systems, bots and other machines, or are they from us? Can we control them? And if so, how? Is transhumanism inevitable as a way of a significant change in the human body and soul? Will they force us to modernize and complement, if we want to gain access to jobs, education and healthcare? Who and on what basis will own information technologies and systems? Could this lead to even greater inequality than what already exists today, based on access to information flows? Will access to computer technology be open to anyone? [7].

Due to the need to answer emerging questions, the main task is the modeling of digital humanism, and attempts are already being made to model it. So, the Scheherazade system is already capable of generating texts from the Amazon Mechanical Turk crowdsourcing platform based on semantic similarity. To achieve this goal (getting medicine in a pharmacy), a self-learning system analyzes, according to the chronological principle, all the events that people may encounter in reality. At the same time, the principle of the characteristic character of ordinary legitimate human behavior was laid in the artificial intelligence algorithm, so the interface did not choose an offense (theft of medicine), although this was the most rational solution, but an ordinary act based on moral dogmas [8]. However, in our opinion, such behavior can hardly be called purely ethical; nevertheless, moral and ethical standards cannot always correspond to certain algorithms; certain feelings and associations can serve as their motive.

As we see, at the present stage of the development of the information society, the following problem arises: is there a difference between artificial intelligence and "natural intelligence", recognized as the main quality of a person, while, as noted above, associated with thinking. In the foreign scientific literature on artificial intelligence, its characteristics are distinguished as: "weak", intended only for certain tasks, and "strong" (general) artificial intelligence, a special technology capable of solving a wide range of tasks by analogy with the human brain [3].

Already today a person, as a biological species, using virtual reality, receives an artificial body-avatar, into which in the future it will be possible to transplant

a natural intelligence (human consciousness) using digital technology or a direct brain transplant. Such a Homo Virtual will have digital immortality, therefore the very concept of life, as a form of existence of real material objects, will acquire a completely different ontological meaning, human life will be determined through existing specific information about it stored on technical devices. Another predictable scenario may be the temporary use by a person of an avatar body through accession to artificial intelligence (computer). People will be able to "move" into cyberspace, in which the digitized consciousness will exist almost forever in an individual virtual space. People "living" in cyberspace will not need social relations and their regulators; accordingly, new communication vectors (for example, social networks) will arise that require a fundamentally different legal regulation. In the field of material goods production, with the development of NBIC technologies, special nanomechanical devices (molecular nanomachines, including nanoassemblers) will be created [4, 5], which are cheap labor and can solve almost any problem, which, of course will affect the field of labor law and social security law. In the near future, society will consist not only of people with natural intelligence, but also avatars, zombies [1], etc., and therefore the sign of "humanity", conscious morality, as a basis for today's type of legal regulation, can disappear irrevocably in the strength of another value basis for determining artificial intelligence, based on the recognition of the insignificance of consciousness.

Therefore, in order to create legislation defining the place of artificial intelligence [12] as an object of legal ontology in the modern information society, a special space is virtual reality, which, in the opinion of G. A. Gadzhiev, is just like "new technical opportunities information transfer creates a situation close to a deep crisis of law" [6]. So far, the reasons for the "crumbling" of the modern system of law can be issues that are not resolved by legislation and, first of all, the need to legally define each of the intellectual systems; assignment of artificial intelligence, intelligent systems and other objects of information technology to subjects or objects of legal relations; determining the content, types and characteristics of legal liability for incorrect decisions or actions of artificial intelligence; the rights of artificial intelligence, the characteristics of labor and tax relations, provided that employers use it, the content of digital humanism, etc. [14].

The issue of assigning artificial intelligence, cyberphysical systems, various kinds of neural systems, different robots and robotics objects to objects or subjects of law is paramount for their legal regulation. V.I. Shershulsky, director of technology policy at Microsoft, notes that the production of information is no longer in the field of activity of a person, but of neutron and cyberphysical systems, becoming full-fledged economic entities, and, therefore, should be vested with the right to make payments, therefore, various technologies need immediate legislative consolidation.

4 Conclusion

The need for the legal regulation of artificial intelligence, robots and robotics objects is actualized by their use as drivers, police officers, musicians, doctors, lawyers and brokers, insurers, etc. (Jurisprudence). We believe that the problem of the legal personality of artificial intelligence and robotics objects, in the broadest sense of the term, can be solved in two ways. On the one hand, they can be considered as an object of a legal relationship, in the case when it is called upon to perform actions for a person, and on the other hand, its definition as a quasi-subject of law, due to its cognitive abilities. Another question remains unresolved. Is legal regulation of artificial intelligence, cyberphysical systems, neural networks, robots and robotics objects possible exclusively in the format of national law? Yes and no. On the one hand, the legal space of individual countries is different in their substantive features, and, therefore, legal traditions, depending on the affiliation of national systems of law with legal systems, interpret the features of legal regulation. On the other hand, the use of artificial intelligence, robots, and other objects of robotics, as a factor that changes almost all spheres of an individual's life, should be determined by the international community. All this actualizes the need for the immediate formation of the concept of legal regulation of artificial intelligence, robots and robotics objects in the Russian Federation.

The System of Law and Artificial Intelligence in Modern Russia: Goals and Instruments of Digital Modernization

Anna V. Popova, Svetlana S. Gorokhova, Marianna G. Abramova, and Irina V. Balashkina

Abstract *Objective*: in Chapter the aim is to identify the issues of goal setting, creating a legal regulation of cyber-physical systems, neural systems, created on the basis of artificial intelligence, robots and robotics, the authors believe that such a General goal-setting due to the complex internal and external factors related to the discrepancy of the regulatory framework to new technological conditions and the level of development of science and technology, the emergence of new problems of globalization, the struggle for technological superiority. *Design/methodology/approach*: the article considers approaches to determining the principles and objectives of the development of artificial intelligence, robots and robotics objects, the most effective development of which should contribute to the implementation of the provisions of the National strategy for the development of artificial intelligence. The methodology of the Chapter consists in the use of methods of interpretation of legal documents and formal and logical tools not only in the system, but also in comparative legal analysis of existing strategic and regulatory legal acts of foreign States that determine their policy in this area. *Conclusions*: the conclusion is made about the need to strengthen the legal regulation of artificial intelligence, robots and robotics objects. Setting the objectives of legal regulation in the field under study, depends on the formulation of not only General, but also specific goals of improving legislation in the field of artificial intelligent systems and robotics. *Originality/value*: the solution of these tasks, according to the authors, will contribute to strengthening the digital security of the individual, society and the

1 Introduction

President of Russia Vladimir Putin in his Address to the Federal Assembly of the Russian Federation noted that Russia should launch a large-scale national program for the development of artificial intelligence, which requires creating an advanced scientific infrastructure that will help Russia become one of the leading countries in scientific technological areas. On October 10, 2019, by Decree of the President of the Russian Federation No. 490, the National Strategy for the Development of Artificial Intelligence until 2030 (hereinafter referred to as the National Strategy) was approved, which defines the terms, goals and objectives of Russia's development in this field.

The indicated strategy, generally evaluated by the authors of this article, is positive, as a step towards creating a modern legal and organizational framework that regulates issues related to the inclusion in the legal turnover of specific institutions that interact with artificial intelligence, however, is not free from a number of shortcomings. Firstly, the very name of the Strategy, as well as its text limits the direction of strategic planning only to the sphere of development of artificial intelligence, without mentioning robots and robotics interconnected with this area. We believe that a broader range of strategic planning issues would be a more systematic approach, combining artificial intelligence—as technology, and robots (robotics)—as the main carriers of artificial intelligence technologies.

Secondly, meaningfully being a very general document, the National Strategy for the Development of Artificial Intelligence until 2030, however, reduces the sum of the fields of application of artificial intelligence and its capabilities to particular, little-defined moments. So, for example, paragraph 21 of the National Strategy, determining that "the use of artificial intelligence technologies in economic sectors is of a general ("cross-cutting") nature", further, in the subclauses of this paragraph, listing the conditions for improving efficiency and the formation of fundamentally new lines of business activity subjects speaks of: improving the efficiency of planning processes; automation of routine (repetitive) production operations; optimization of selection and training processes; etc. That is, positions that do not reflect any specifics of introducing artificial intellectual systems into circulation, and can be attributed to any direction of the development of scientific and technological progress. Such an

approach, according to the authors, cannot be considered successful, since the solution of national tasks in the field of the development of artificial intelligence technologies is possible only in a systemic way that combines strategic planning in a comprehensive technological area—artificial intelligence—robots—robotic systems, and structured the legal direction, which implies building on a unified theoretical basis sectoral typified institutions regulating social relations with pation of artificial intelligence. It should be noted that the National Strategy for the Development of Artificial Intelligence does not sufficiently specify the directions of the proposed legal transformation, indicating only that by 2030 a flexible regulatory system in the field of artificial intelligence should function in Russia, including guaranteeing the safety of the population and aimed at stimulating the development of artificial technologies intelligence. We believe that the implementation of the task will depend, inter alia, on the scientific research conducted in this area on the specification of the internal content of upcoming changes in the relevant branches of Russian law. A similar attempt was made in our study.

2 Materials and Method

Based on the conducted research, one can determine the conceptual foundations of the legal regulation of technologies in the field of artificial intelligence (Fig. 1).

As already noted, the social relations existing at this stage of scientific and technological development have determined the need for transformation of the legal component of the social interaction of natural (human) and artificial intelligences, primarily by including new terms that go beyond the framework of the legal thesaurus created over the centuries, categories, definitions in legal routine to characterize the new economic structure of the digital society. Artificial intelligence is the subject of scientific research by both Russian and foreign authors [1–8].

New opportunities, and associated new risks and threats for the state, society and individuals, create a situation where the legal field, at a minimum, must adapt to the embodied reality, and at the very least, create a "reserve" for further compliance with the developing social technologies relations, in general, and legal, in particular [9–12]. All this is an indisputable justification of our goal of developing the legal regulation of cyberphysical systems, artificial intelligence, neural networks based on it, as well as robots and robotics objects, which can be graphically represented in the following diagram (Fig. 2).

As can be seen from the presented scheme, the formation of the need for legal regulation of the use of cyberphysical systems, artificial intelligence, neural networks based on it, robots and robotics objects directly depends on those that appeared from the end of the twentieth century. new factors, both positive and negative, affecting almost all areas of public life. These factors, being very diverse in nature, in turn, determine the same different goals of improving legal regulation [13–16].

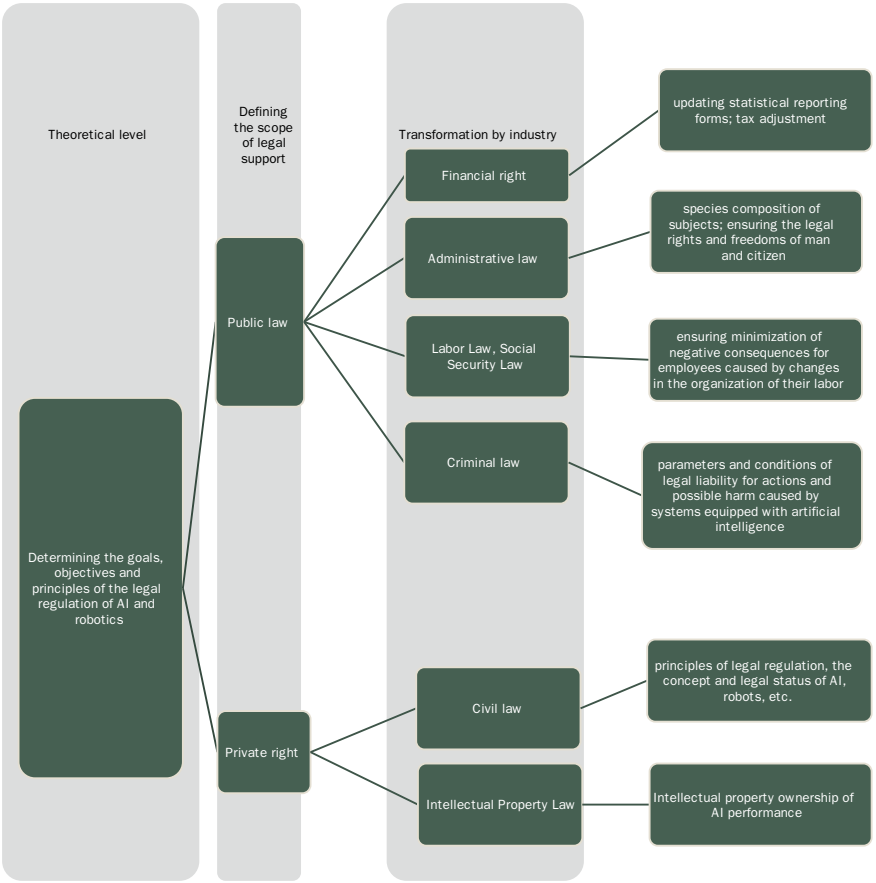

Fig. 1 The concept of legal regulation of technology in the field of artificial intelligence (Compiled by the authors of the section on the basis of a comparative legal analysis of legal documents and scientific literature)

3 Results

It seems to the authors of the chapter that the goal of updating the legislation on labor and employment, social security is to minimize the negative consequences for workers caused by changes in the organization of their labor (and possible loss of jobs) due to the massive involvement of artificial intelligence, robots and robotic in the production processes technicians. The goal of improving civil law should serve, based on their new realities, the inclusion in the legal array of this industry of norms defining an entire agglomeration of positions, starting with questions of defining the very concept of artificial intelligence in a compartment with the construction of its legal status, and ending with questions of whether intellectual property belongs to performance results artificial intelligence, including industrial property law.

Fig. 2 Formation of needs and substantiation of the goal of the legal regulation of artificial intelligence, robots and robotics objects (Compiled by the authors on the basis of a comparative legal analysis of legal documents and scientific literature)

The actual goal of its improvement in the field of criminal and administrative legislation is to clarify the species composition of subjects of law in these areas of legal regulation, parameters and conditions of legal liability for actions and possible harm caused by systems equipped with artificial intelligence, various kinds of robots and robotics objects. In addition, the jurisdiction of the indicated branches of law and branches of the law covers issues of ensuring the legal rights and freedoms of man and citizen, including privacy, confidentiality of correspondence, honor and dignity of the person. So, one more separate goal is seen here—ensuring and protecting the legitimate interests, rights and freedoms of various subjects of law. Separately, within the framework of administrative law, we can talk about creating a modernized public administration system that includes new executive bodies aimed at overcoming the existing administrative barriers to the development and implementation of intelligent digital systems that will deal with ethical control over these developments (including and dual-use), licensing of production and ready-to-use devices, their standardization and others associated with these, in polls.

Promising, of course, is the use of intelligent systems in the field of public safety. The United States has already begun to implement artificial intelligence technologies to ensure public safety. According to American researchers [17], by 2030 a typical North American city will rely heavily on them. Such developments include surveillance cameras that can detect anomalies indicating a possible crime, unmanned aerial vehicles and forecasting police applications. One of the most successful applications of artificial intelligence analytics is the detection of white-collar crimes, such as, for example, credit card fraud. Artificial intelligence tools can also be useful in helping the police monitor potential crime sites or search and rescue activities.

The banking sector of the Russian economy today is the flagship in the use of neural networks, cyberphysical systems, etc. It is enough to cite Sberbank of

Russia, whose specialists use artificial intelligence in various areas of the banking sector. Thus, a "technical solution for forecasting the revenue of small, medium and large businesses" was developed, a special forecasting model built using machine learning algorithms, […] based on the Random Forest algorithm used for classification, clustering and regression problems and using a large number of trees decisions "in order to" predict the defaults and bankruptcies of companies and individual entrepreneurs [18]. Since February 2019, a chat bot based on the NLP AI platform (Natural Language Processing) has been working for the development of the Sberbank Markets e-commerce system, the task of which is to communicate with users of the site, advise them on the course of trading, conclude transactions and other.

Determining the general goal-setting of the legal regulation of artificial intelligence, robots and robotics objects, we note that it is due to a set of internal and external factors associated with a mismatch of the regulatory legal framework with new technological conditions and the level of development of science and technology, the emergence of a fundamentally different spectrum of risks and threats of social, psychological, economic and legal nature, issues of intensification of global competition and the struggle for technological superiority, and arising from this is the need to preserve the technological and digital sovereignty of our state in the field of the development of artificial intelligence, cyberphysical systems, neural networks, robots and robotics objects.

Based on the foregoing, the goal of developing the legal regulation of artificial intelligence, robots and robotics objects is to bring the entire array of current regulatory legal acts into line with the conditions dictated by the level of development of scientific and technological progress in the development, creation, and operation of autonomous intelligent systems, taking into account internal economic and external geopolitical factors, legal rights and interests of citizens, and general parameters for ensuring national security.

To achieve this goal, a consistent solution of the following particular problems is necessary.

1. Determination of the legal status of the key categories of "artificial intelligence", "robot", "bot", "robotics object", "robot", "android", "digital personality", "electronic face", etc. to determine their place in structure of legal relations.
2. Formation of two agglomerations of principles in the field of development of AI, robots and robotics objects, one of which should be addressed to designers, manufacturers and operators of robots, the other to law-making authorities responsible for the development and adoption of regulatory legal acts regulating them.
3. Monitoring and forecasting of possible social, economic, legal and other consequences of the spread of intelligent artificial systems in various areas of public life.
4. Introducing appropriate changes to the civil legislation system, taking into account previously developed theoretical concepts of the basic terminological apparatus, the classification of "smart" robots, determining their legal status and place in the structure of legal relations.

5. Adjustment of intellectual property law and patent law to new conditions, subject to changes in civil law.
6. Improving legislation in the field of science and education, to ensure compliance with the requirements of the digital economy and maintain the competitiveness of the state in the field of the development of artificial intelligence and robotics.
7. Inclusion in the transport legislation of the rules governing the operation of autonomous (unmanned) vehicles, and other provisions related to the use of artificial intelligence in the transport sector.
8. Determining the types of legal responsibility of artificial intelligence, robots, robotics objects in various areas of legal regulation, including identifying the culprit as the most important aspect for this institution of law. Amendments to the Criminal Code of the Russian Federation and the Code of Administrative Offenses of the Russian Federation.
9. Introduction of short stories into the procedural legislation of the Russian Federation, coupled with the above changes in the branches of material legislation.
10. Formation of new approaches in statistics, taxation, investment and insurance activities.
11. Modernization of the state administration system, with the introduction of appropriate changes to the norms of administrative law.
12. Updating the regulatory framework governing the activities of law enforcement agencies, in order to ensure and protect the legitimate rights and interests of the individual, including the right to confidentiality.

4 Conclusion

Thus, the overall goal of developing the legal regulation of artificial intelligence, robots and robotics objects is to bring the entire array of current regulatory legal acts in accordance with the conditions dictated by the level of development of scientific and technological progress in the development, creation, and operation of autonomous intelligent systems, taking into account internal economic and external geopolitical factors, legal rights and interests of citizens, and general parameters for ensuring national security. As the private goals of legal regulation, one can single out the need for the transformation of certain branches of law caused by specific factors accompanying the introduction of artificial intelligence in various spheres of public life. First of all, we are talking about changes in civil, criminal, administrative law, in procedural branches, and a number of other branches and institutes of law. The statement of the problems of legal regulation in the field under study is determined by the main goal of improving the legislation in the field of application of artificial intelligent systems and robotics. The key point in the legal regulation of artificial intelligence is the question of giving it the status of a subject or object of legal relations, or a hybrid version of the status.

The Application of Artificial Intelligence for the Identification of Relevant Forensic Information Among Video Surveillance System Data

Ily'a O. Prichko and Aleksandr D. Afanasyev

Abstract *The purpose of the paper* is to demonstrate the applicability of artificial intelligence methods for the identification of relevant forensic information from records of video surveillance systems and the opportunity to classify this information by the level of forensic relevance from potentially significant to less important events. *Methodology*: The paper deals with common problems related to the work of a criminal investigator, provides their analysis, and offers solutions based on modern AI developments. The solutions are justified by the new capabilities of mathematical simulation and numerical methods and specially designed programs. *Findings*: The paper offers a comprehensive solution for the identification of relevant forensic information, which allows achieving high efficiency against conventional approaches as well as reducing man-caused errors. It has been remarked that the most usable form of an efficient video review tool is a comprehensive solution involving the following processing stages: (1) Reducing non-informative events to a minimum and using video frame space in an efficient way; (2) Classification of objects and search by required criteria; (3) Identification and re-identification of people between all sources of video streams. This three-stage solution will help the investigator to focus only on the events that are relevant to the investigation. Besides, there will be new opportunities against conventional methods. The paper discusses some constraints that may serve as a guide for future research.

1 Introduction

In the modern world, informational traces left by offenders are playing an ever-increasing role in the investigation. The sophistication of computers, information networks, and technologies leads to the annular growth of information sources and their volume, which poses to law enforcement bodies the challenge of processing big data to identify relevant forensic information. The main obstacle to a comprehensive and full-fledged assessment of evidence is the limited time of the investigation and insufficient staff. The application of advanced technologies for the imposition of routine tasks on a computer can solve the above problem subject to their execution with permissible tolerance. To date, computer technology and machine learning methods allow solving tasks without human control.

Against the background of the aggressive development of the security systems industry, video recording complexes are popular for end consumers due to their affordability and usability. The information recorded in video surveillance systems is of high, and sometimes, key importance for investigative and inquiry bodies to solve and investigate the crimes.

A fixed video recording system [also known as a closed-circuit television system (from English CCTV)] is a hardware-software complex consisting of a recording and storage device (video recorder), as well as video surveillance cameras and other integral parts. A variety of such systems and methods for storage of video files created problems of their extraction but nowadays the development of specialized software systems and hardware causes the challenge of their subsequent analysis to identify relevant information for the investigation process. It is highly important that viewing a great deal of surveillance camera records takes much time and triggers human error or the inability to have regard of all respects of the event (for example, multi-day surveillance in cases of contract killings or robberies, or multiple preparations of the same people in different places). Besides, the human efforts spent on the extraction of relevant information from video records can be underestimated due to the absence of information in the objects under examination.

Let's try the real situation where an unidentified person attempted on the life of a woman with a baby and stabbed a victim multiple times in the central park. To find the criminal and witnesses, the investigators extracted video records over a long period from surveillance cameras around the park on the way of possible arrival/departure of the criminal. The investigators have had more than 500 h of video records from over 100 surveillance cameras involved in 40 video recording systems. The processing of the records required a great number of operational staff, as well as investigators and forensic scientists. As a result, the crime committer, as well as the path of his escape until the departure from the city by route transport, have been detected.

The problem of searching for key objects in this situation is not simple since it takes enormous human resources. People are designed in such a way that the brain adapts to external stimuli and starts losing the eye of external changes over time.

In our case, incompetent person after an hour of video reviewing misses course of events and the situation deteriorates with time, but as for crimes we are not talking

about one camera and one hour. Hence, the attention is dulled and key information may be lost due to the fault of the human factor. Thus, currently, there is a task of developing a video record analysis tool under which the investigator wouldn't take irrelevant information into account.

This article discusses current solutions applied to process video records for subsequent detection of relevant information. The first method is "video synopsis" [1] designed to detect actions on the video frame and then combine them in a single video sequence for efficient use of the time frame space. We'll talk about this method in Sect. 2. There is also a method of machine learning application for video data analysis to extract classification information from the video sequence. It's a typical task of object detection and classification [2] that we'll dwell on in Sect. 3. One of the groundbreaking methods of video analysis is person re-identification technology [3], which is based on a comparison of people detected in the video frame with previously detected, including ones on other cameras and over different times. Person re-identification is thoroughly described in Sect. 4.

2 Videosynopsis

The problem of getting relevant information from video records has been raised for many years. The demand for tools capable to extract key data from a video stream is growing steadily every year due to ever-higher informatization of the urban environment and wide use of video recording systems. For example, three people were killed and 264 were injured in the Boston terrorist attack of 2013. FBI staff reviewed over 13 thousand records from video surveillance cameras and mobile phones of the marathon spectators and ultimately detected the criminals within three days [4]. It is the video synopsis mechanism that made it possible to facilitate the record analysis.

The term "video synopsis" was introduced by the authors Yael Pritch, Alex Rav-Acha in 2006 [2]. It has relied on the notion of "synopsis", the idea of which is to concisely present information without losing the main events. If the talk about the synopsis of video records, this is to present video data in non-chronological order and keep the main actions from the primacy source, including taking full advantage of the video frame space. Of course, video synopsis is primarily aimed at selecting objects on the video record and putting their actions in a single video sequence, which allows reducing uninformative data to a minimum and overlapping several actions, even though they occurred at different time. An example of video synopsis generation is shown in Fig. 1.

For the application of this tool, the authors detect inter-frame changes (motion detection) and analyze their movements (tracking of objects), and further integrate the resulting information into a database of objects and actions. Currently, video synopsis researchers [5] have agreed on a single methodology where the generation of video synopsis starts with object identification, then follows tracking of its motion,

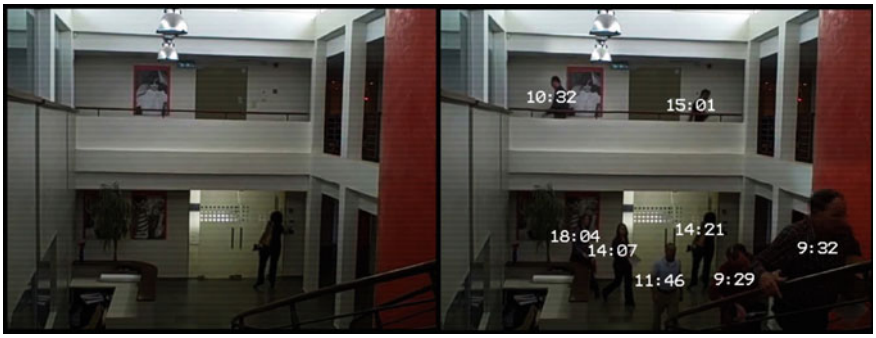

Fig. 1 An example of a video synopsis generation. The left part of the figure is the original video, the right part is the generated video synopsis. *Source* The author is rachelneim; BriefCam, Ltd.

clustering of actions for joint display of similar actions and their subsequent optimization. Finally, periods are calculated for selected actions and activity is overlaid on the generated background.

As of today, video synopsis is focused on the clustering of the received objects and their actions to mitigate collisions and enhance efficiency [5]. The main challenge arising in processing videos with numerous actions in the frame is the processing of motion path collisions since they can cause the loss of important content, which in turn lowers efficiency. Thus, displaying the greatest number of objects with the lowest collisions requires vast computational resources.

As an example, let's consider a real-life situation. There has been detected weapon cache and a video recording system with 18 surveillance cameras, containing records for over 20 days, next to it. Due to the lack of data on the scope of persons and the time of any actions taken with the cache, the investigators have to review all the records. It's peculiar that there were motions in various sections of the video frame, which precludes simple rewind methods until activity occurrence. In this situation, the generation of a video synopsis for the entire period for the cameras in interest allows selecting only video clips containing an activity that is relevant for investigators.

Presently, the identification of objects in videos in one form or another form is based on time frame change (motion) [5], but in these circumstances, we deal with no motion (or with low interferences perceived as noise). Therefore, important information may be missed, or on the contrary, the video may contain a great deal of irrelevant motion like the noise of leaves or precipitation.

The modern development of computing facilities, as well as pilot research deep learning neural networks, provide an opportunity for video data analysis for the detection of objects and their classification. It is worth noting that the current progress in the segmentation of objects (identification of boundaries) allows identifying people and cars and taking them directly out of the background (segmentation). But here we deal with the problem of significant incrementation of computing capacities required to video record processing, which requires more comprehensive results in addition to the generation of a video synopsis.

Detection of objects in videos using deep learning neural networks also opens up the opportunity of their classification, which ultimately allows you to find objects of interest by the required criteria. Undoubtedly, to date the share of high-quality surveillance cameras is not ubiquitous and learned neural networks on identification and classification of objects may miss low-quality fragments (for example, at a distance), therefore the development of a hybrid model concerning motion detection can reduce the percentage of errors caused by data inaccuracy.

3 Detection of Objects and Their Classification

The next stage in the development of video analysis technologies is the object analysis of video content through the detection of objects and the identification of their characteristic features. The current development of artificial intelligence makes it possible to identify people and cars even on low-quality videos while attributing to them characteristic features. For example, for people it is a face descriptor, physical parameters (ethnic background, sex, age), garment, hairstyle, etc.; for cars, it's brand/model, license plate, color. This information helps to select video clips with matches to certain parameters known to the investigatory bodies. Often the investigators take possession of the information on the alleged offender, for example, a photo of the suspect, age/sex/ethnic background, garment, etc.

To date, there has been a lot of studies dedicated to object detection and classification, as well as ready-made modules and learned models of neural networks. As for the classification of cars, then studies [6, 7] have created the opportunity to define the brand/model of the car and identify license plate symbols. Besides, deep learning neural networks also allow detecting the color of a car [8], even though its perception may differ due to illumination. If the video contains a human face, modern solutions enable its identification using a comparison of face descriptors (describing a set of numerical values) [9, 10] and prediction of sex and age of the person [11]. Along with that, by the decent quality image of a person's face, it is possible to suggest his ethnical background [12] and other attributes, such as a mustache, beard, hairstyle, face hiding elements. In addition to the above descriptive characteristics, it became possible to identify the garment attributes [13].

The authors of the study [14] suggest the utilization of unique data about the gait of the person in addition to appearance identification since the appearance is not always sufficient to distinguish the people in videos, because the garment can be nearly the same or it can be the uniform. Moreover, the garment may change over time, especially in winter.

Therefore, it is suggested to use gait identification methods. As a result of experiments held in the course of the study [14], we have found out the correctness and permissible tolerance of person identification using gait comparison.

Let's provide an example justifying the importance of research in this area. In a big city, there has been committed a murder and a T-shirt with typical visual signs (in blue and white stripes) of the victim's blood has been found within several streets from

the rubbish bin. A large number of cameras between the crime scene and the place of the T-shirt location, as well as the absence of a camera directly in the detection area, preclude the identification of the offender on the video within a reasonable time due to high flow of pedestrians. In this example, the selection of people who meet certain criteria allows identifying the suspect and find video clips on which the escape route or his face could be captured.

Summarizing, we can stress a high particularization of the classifying features for objects with permissible tolerance, but with that, the computational capacities required for the solution of the tasks set are sufficient in the event of a large number of objects in video records.

4 Person Re-Identification

The next step after indexing and classifying objects is comparing them with ones obtained earlier, including objects on other video devices [15, 16]. This action allows reveals patterns and monitoring the movement of faces between cameras. The convenient method of reviewing extracted videos causes many troubles due to the need of switching between records from different devices. The application of artificial intelligence for the identification of human attributes helps to design numerical descriptors to make up a single database of objects in interest among a set of videos. After all, selecting an object on one record will make it possible to draw up a motion video sequence of this object among other records.

Figure 2 presents a situation when people fall into the viewing area of different cameras, and usually, there are many intersections, which makes it difficult to track the route of people's motion.

One of the challenges for the investigator in reviewing video records is tracking the motion in shopping centers and other crowded places that are stuffed by many surveillance cameras. For example, for proving the guilt of certain individuals on the explosion in a large shopping center, 10-terabyte video records from 83 surveillance cameras over three weeks have been extracted. The investigators didn't know the exact time of movement of the explosive materials, but they had the photos of the suspect. Under these circumstances, the mechanism of person re-identification between video streams allows revealing not only time frames of capturing the suspect's face through face recognition, but also draw up a video sequence of all motions in the shopping center for the required period.

The operation of person re-identification methods [17] is similar to solving a typical task of identification by face, during which a descriptor of a person is being formed [18], and after it is compared with the descriptors stored in the database.

The level of descriptor vector approximation shows the probability of their belonging to the same person. Also, one of the research trends is the analysis of both global human attributes (descriptor calculation) and local appearance attributes (distinctive features) [15] (Fig. 3).

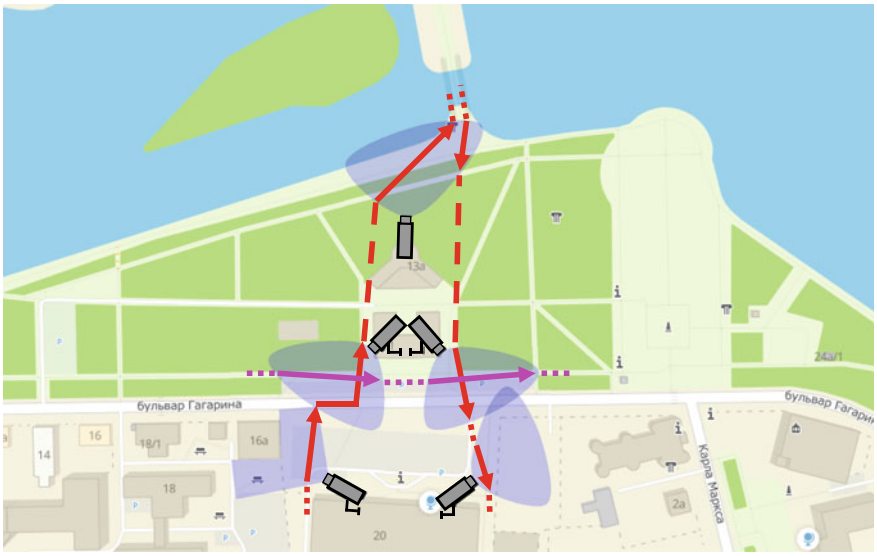

Fig. 2 Diagram representation of human interaction with surveillance cameras. *Source* Developed and compiled by the authors based on 2GIS services

Fig. 3 Example of images from a database for re-identification training. *Source* CUHK person re-identification datasets. https://www.ee.cuhk.edu.hk/~xgwang/CUHK_identification.html

Relying on the analysis of current publications in the field of video analytical research [3], person re-identification is regarded as a priority line of development. The current importance of this topic is explained, inter alia, by the increasing demand for China's participation in monitoring of the urban environment using video recording cameras and their content analysis.

5 Conclusion

On the back of the analysis carried out by us, it is evident that nowadays the most convenient form of introducing an efficient video review tool from fixed video recording systems is a comprehensive solution with the following processing stages: (1) Reducing non-informative events to a minimum and using video frame space in an efficient way; (2) Classification of objects and search by required criteria; (3) Identification and re-identification of people between all sources of video streams. This three-stage solution will help the investigator to focus only on the events that are relevant to the investigation. Besides, there will be an opportunity of analyzing the movements of all individuals to identify suspected behavior (spying, preparation for a crime, suppression of the traces of a crime, etc.). Thus, the examples indicate the high importance of developing AI-based hardware for forensic scientists. Therewith, deep learning neural networks for identification and classification of objects on video records require enormous computational capacities, therefore, the related costs should be justified by an integrated approach but not the solution of specific tasks.

Conceptual Approaches to Formation of Machine Building Product Development Systems

Ekaterina P. Garina, Elena V. Romanovskaya, Natalia S. Andryashina, Victor P. Kuznetsov, and Sergey D. Tsymbalov

Abstract The article evaluates scientific works in the field of conceptual design of product development systems. Their systematization allows to determine the principles of conceptual modeling of systems, methods and tools used to generate and systematize information on a product during its conceptualization. It also proposes the author's definition of the product development systems concept. Project practices are considered on the topic of research of the modern stage of domestic engineering development in the Russian Federation, including: factors of product development systems by industry enterprises, classic solutions to the issue of domestic production development at the present stage and scenarios of development of Russian mechanical engineering. Proposed concept based on the management of product development systems takes into account relevant practices of corporate systems (product development systems, production systems) of domestic manufacturers. Development of systems by industry enterprises is recommended to be considered in the context of: (1) government as a strategic regulator of the system; (2) participants in systems and their initial basic conditions (engineering and technical performance indicators) that determine the degree of adaptability and perception of technology.

1 Introduction

Generating a product concept is a significant step in the engineering process of a product system. At this stage, an abstract description of the product is created, which serves as the basis for the subsequent stages of system design and decision-making on their development, i.e. decisions are being made on the creation of the product. By *product development it* is proposed to understand the process of multi-dimensional adaptive integration interaction of the system participants. It is based on the achievement of a balanced process (business processes, technological processes) in the implementation of common goals for the project.

In the works of scientists related to the formation of the concept of a product [1, 2], various interpretations of the "concept" are proposed—these are:

- clearly stated idea and/or strategy of the future product development project;
- description of the product, technology, production systems and production processes.
- detailed description of attributes and advantages of created product that meets the needs of target consumers;

That is, in fact, the concept is a preliminary description of the future of the product and conditions of its creation. Purpose of which is to create the basis for the subsequent physical design, production and commercialization.

Analysis of scientific works in the field of conceptual design of product development systems [3–6] and their systematization made it possible to formulate a number of conclusions:

- principles of conceptual modeling for product development systems are: (a) openness of the product system—modularity of the product-production systems; (b) multidimensionality—under conflicting conditions, situations that were previously considered as conflicts can stimulate the generation of new ideas; emergence—properties of a system acquired as a result of the interaction of elements, and systemic use of which determines synergy.
- methods of conceptual modeling of systems are: (a) parallel design—a systematic approach to integrated, simultaneous design of products and related processes, including production and support; (b) cascade method (the "waterfall method")—a traditional chain is formed of the initially set stages of the product development life cycle in the form of successive stages of the product design, implementation of the concept, testing, system integration and support; (c) a flexible method of product development—based on short iterations with a dynamic cycle of determining the requirements for the product and the process of its creation at each stage by self-organizing working groups of specialists in various fields.

- tools used to generate and organize information on a product during its conceptualization (also related to processes used in production): (a) functional analysis—method involves determining the degree of customer satisfaction with the product: • in terms of product functionality and needs that are being met (functional needs analysis); • in terms of the degree of satisfaction of these needs (technical functional analysis); (b) the method of structural analysis and design (SADT)—a method of analysis and creation of a product as a system that facilitates communication between specialists in various fields in a PD project; (c) deployment of the quality function (QFD)—the quality control method allows you to assess the degree of customer satisfaction throughout the product creation cycle. Applicable to both product and process; (d) analytical process of hierarchies—the methodology of multicriteria analysis and decision making, developed by Thomas L. Satie;
- the general process of product conceptualization is highly dependent on the context in which decisions are made (the context of business and the environment) [7]. The decision-making process should take into account the possibility of changes in the design, production parameters within the specified limits of the design concept. Tools can be: (a) methodology of analysis of failures and effects (FMEA)—based on a preliminary assessment of the reliability of PD-systems and analysis of their potential failures; (b) Taguchi method—reaction of the product to the variability of production factors is evaluated; (c) SixSigma methodology—defines a quality culture of the strategies and tools used to improve the efficiency and effectiveness of systems.

Based on the foregoing, *the concept of product development systems* is a set of theoretical provisions and practical recommendations that determine the nature, possible ways and tools for solving problems associated with the formation and strategic development of product development systems at engineering enterprises.

The conducted researches allowed to define and systematize the basic elements of the concept of formation of systems for product creation, realized at present by manufacturers of the industry (Fig. 1).

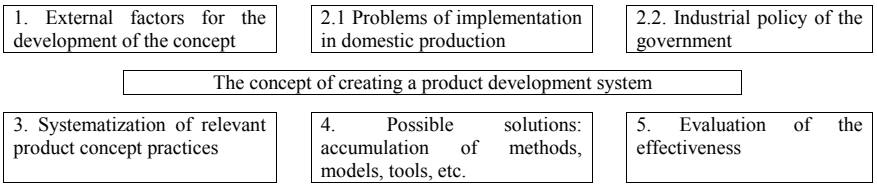

Fig. 1 The concept of a product development system in the enterprise

2 Results of the Study

Based on the concept under consideration at the present stage of development of domestic engineering:

1. The classic models of production development are being replaced by the concepts of transformational, flexible, adaptive, integrated corporate systems aimed at meeting not only the implemented production paradigms, but also future ones—sustainable development strategies [8]. External factors limiting the development of the concept of product creation systems in Russia in comparison with industry leaders (Table 1):
2. Internal factors limiting the development of the concept of product development systems in Russia [9]:
   - production of most domestic OES components and spare parts for a specific OEM;
   - absence of the majority of domestic OEM- OESs- manufacturers as current and strategic goals for creation of integrated adaptive production systems and technologies for complex high-tech products (Table 2).
   - development of production and product creation technologies relate to individual transformations in component materials, processing of parts and process support, less often—design of individual components and product

Table 1 External factors in the development of product creation systems by industry enterprises

Aggregated Factors	USA	Europe	Asia	Russia
1. Regional features of PD-systems	Leadership and standardization	Energy efficiency, flexibility, performance; transformational	Without losses and extra resources	In the process of formation
2. Focus on development	Integration of processes and systems, supply systems, cross-functional modeling	Flexible automation of production, product-production systems	Autonomization, IT technologies in production design, continuous improvements	Development of flexible production networks, integration of OESs-FTSs-participants in the process
3. The role of PD systems	System integration, optimization of processes and systems	Process optimization	Lean manufacturing management	Adaptability of the production environment, corporate systems, production technologies
Basic concepts	Six sigma, restriction theory, etc.	Process management, time management	Lean production	Lean production

Table 2 Classic solutions to the issue of development of domestic production at the present stage

Main directions	OEMs	OESs	Retail and distribution
In order to increase the interaction of market participants	• Focus on increasing product value/cost of ownership for customers • Opportunity to obtain benefits in the formation of value added	• Collaboration with possibly large market participants • Component expansion • Implementation of world standards in the production of product components	• Development of service and post-sales service • Formation of long-term relationships with suppliers • Encouraging manufacturers to produce complex products
Product development	• Modification of models to the needs of target consumer groups • Supply growth in the business segment	• Improving technology efficiency • Lower production costs	• Product sales complete with additional services • Development of communication mechanisms
Formation of business models	• Cooperation with foreign manufacturers in order to use their technologies, platforms, models, etc.	• Formation of strategies for sustainable and long-term revenue growth	• Using social media and online sales • Cooperation with international investors
In the context of market development	• Formation of financially dependent business units	• Creation of strategic alliances with equipment manufacturers, and R & D centers	• Formation of a multi-brand retail strategy • Creation of centers for after-sales service
Supply chain development/value chain	• Control of production localization programs by market participants • Monitoring benefits offered by the government	• Development of enterprise management systems • Creation of production capacities in special economic zones	• Assessment of production growth potential

as an independent unit. But almost never—a comprehensive transformation of product creation systems, production and technological, control systems.

- factors inhibiting the growth of local production are: (1) relatively low quality of manufactured components, (according to various estimates, only up to 5% of them comply with ISO/TC-16949); (2) low demand from Russian OEMs; (3) technological lag, which makes it necessary to transfer technologies and product-production standards with their subsequent diversification and adaptation to the conditions of a domestic manufacturer, and also determines the

Table 3 Scenarios for the development of Russian production

Scenario	Current vector	Strategic goals
Production of end products	Domestic OEM—manufacturers are integrated into global groups through the mechanism of localization of production, satisfy up to 30% of demand	Domestic OEM is competitive in global markets (1/3 of products for export). Independent niche player
Component production	Domestic OES—uncompetitive, with strong foreign presence OES	Competitiveness of domestic OES—including on the international level, their high localization
R&D	Only at the level of production sites Engineering and technological support of production	Full-scale R&D for domestic OEM and global markets
Necessary investment	25 billion euros (50%—companies, 50%—government)	40 billion euros (25%—companies, 75%—government)
Realism	High	Low

need to attract investment in the industry for the development and introduction of competitive product and production platforms in the future (Table 3).

Against the background of the full-scale development of international economic cooperation, the orientation of domestic producers on the full cycle of production of the final product nationwide, and development of their own R&D base is necessary.

3. The concept of development of machine-building enterprises on the basis of product development systems should take into account relevant practices of corporate systems development of domestic manufacturers (Table 4).
4. Possible solutions: accumulation of methods, models, tools, etc. (Fig. 2).

3 Conclusion

In accordance with the idea put forward, the development of product development systems by industry enterprises should be considered:

1. In the context of two components: (1) the role of the government as a strategic regulator of the system; (2) OEM- OESs- manufacturers—participants in the systems and their initial basic conditions (engineering and technical performance indicators) that determine the degree of adaptability and perception of technologies. Based on what, the consistency of the concept development factors should be determined by two criteria: control over factors by the government and factor significance level for strategic development of business units.
2. The original production paradigm; product creation practices;

Table 4 Relevant practices for implementing the product concept in the Russian Federation

Indicators	Values
1. The share of individual concepts of management and organization of PD-systems	
TQM, 6 Sigma, 20 keys, etc., number of enterprises/share	25/5%
Kaizen, number of enterprises/share in total	25/5%
Business system, number of enterprises/share in total	25/5%
Lean system, number of enterprises/share in total	143/28.6%
Product system, number of enterprises/share in total	282/56.4%
Production system, number of enterprises/share in total	78/31%
2. Costs of manufacturers for implementation and development of corporate systems	
Avtocomponent, costs—percentage of revenue	2%
Saransk plant of dump trucks RKTM	0.2%
Elabuga Automobile Plant	0.2
Volgograd Engineering Company KTZ	0.1
3. Benefits from implementation and development of corporate systems (production systems, PD-systems)	
In the field of engineering: cost reduction	30% (saving per year 11.5 million rubles)
Reduction of unfinished work	50% (additional annual income 130 million rubles per year)
Release of production space	30%
Labor release	25% (reduction in labor costs—more than 1.3 million rubles per year)
In the automotive industry (KAMAZ OJSC, GAZ Group): cost reduction	30% (saving 65 million rubles for 1 week)

3. Strategic alternatives aimed at overcoming the technological lag of manufacturers: attraction of design and technological solutions for product/production on a patent basis; developing the principle of one purchase—three cooperation; the formation of functional equivalents; developing production potential of the country.

technology:		
New manufacturing technologies (NTP) - "a set of new approaches, materials, methods and processes used for the design and manufacture of competitive products	- Technology of digital twins - digitization of experiments, development of materials, machines, structures, devices, plants, structures, physico-mechanical and chemical processes, technological and production processes. - Formation of the national "Digital Brainware" development of domestic PLM and MES systems - "Smart production" technologies (robotization) - domestic MES-system - planning of production solutions at the level of holdings based on a platform approach	reducing the time for developing high-tech products from 10% to 25%; achievement of target characteristics of the developed product due to virtual tests will increase from 0-15% to 50-100%; an average productivity increase of 2 times and a 30% reduction in the cost of repair and maintenance work; 20-30% reduction in production costs due to elimination of losses in production and more efficient quality management
Sub technologies included in the SCT NTP - shifting the center of gravity in the competition for the stage for developing high-tech products. This is increasing the level of its high technology, and reducing the time for launching new products on the market, cost restrictions, high requirements for the functional characteristics.	1) Digital design, mathematical modeling and product life cycle management, including competitive CAD-CAM-CAE-design subsystems, technological preparation of production, engineering based on mathematical and simulation modeling; 2) optimization technologies (Computer-Aided Optimization, CAO); 3) platform technologies for design process management: design and engineering platforms, product-process platforms; 4) production process planning (Computer-Aided Process Planning, CAPP); 5) technological preparation of production (Computer-Aided Manufacturing Process Planning, CAPP); 6) product data management technology (PDM); 7) life cycle management technologies (Product Life style Management, PLM);	- increase in output per worker by 10-30% depending on the industry; reduction of labor costs by 18-33%; - additional economic effect from $ 600 billion to $ 1.2 trillion by 2025. - an increase in the speed of equipment by 190%, productivity - by 180%; - reduction of production costs by 65%, reduction in lead time by 50%
Tools		
5S; Andon; Bottleneck analysis / Bottleneck Finder; stream alignment (Continuous Flow); Gemba (place of value creation); Heyunka; HoshinKanri , policy deployment; Jidoka; just in time (JIT); continuous improvement (Kaizen); Kanban (traction system, Kanban); SixSigma (Six Sigma projects); KPIs, key indicators; Muda (loss); overall equipment efficiency (Overall Equipment Effectiveness, OEE); Poka-Yoke error protection; root cause analysis; SMED, quick changeover (Single Minute Exchange of Die); 6 reasons for performance loss; SMART goals standardized work;Takttime; TPM, universal preventative equipment maintenance; VSM, creating a value stream map (Value Stream Mapping); Visual Factory

Artificial Intelligence Instruments as the Basis for the Development of the Machine-Building Enterprises Export Potential

Galina Ya. Belyakova, Sergey A. Belyakov, Darya A. Fokina, and Anastasiya S. Shpak

Abstract *Purpose*: The purpose of the chapter it to discuss the use of artificial intelligence instruments as a basis for the development of export potential of machine-building enterprises. *Design/methodology/approach*: The formation of export potential is based on the use of a wide range of modern tools, among which the involvement of artificial intelligence systems in production processes undoubtedly plays a leading role. The research focused on the base of an export potential formation of machine builder enterprises, and the consideration of elements, features and instruments of the export potential forming. As a result of considering the particularities of machine-building enterprises that have leading positions in world markets, it was revealed that they all have artificial intelligence systems implemented to solve various productions, technological or socio-economic tasks of enterprises. The presented article contains recommendations for information technology specialists and managers of machine-building enterprises on the implementation of artificial intelligence systems, based on the study of statistical reports in this area.

1 Introduction

The processes associated with increasing the export potential of machine-building enterprises are complex and involve the implementation of joint high-tech projects with high integration effects and wide participation of economic entities [1], and also involves the use of digital instruments, such as the introduction of artificial intelligence systems into production processes. The term "artificial intelligence" using to describe machines or computers that mimic "cognitive" functions those humans associate with the human mind, such as "learning" and "problem solving" [2].

Today, Artificial Intelligence (AI) instruments have experienced a resurgence following concurrent advances in computer power, large amounts of data, and theoretical understanding; and instruments of AI had become an essential part of production technologies, helping to solve many challenging problems in computer science, software engineering and operations research [3].

According to Bloomberg's Jack Clark, 2015 was a landmark year for artificial intelligence, with the number of software projects that use AI Google increased from a "sporadic usage" in 2012 to more than 2700 projects. Clark also presents factual data indicating the improvements of AI since 2012 supported by lower error rates in image processing tasks [4].

He attributes this to an increase in affordable neural networks, due to a rise in cloud computing infrastructure and to an increase in research tools and datasets [5]. In a 2017 survey, one in five companies reported they had "incorporated AI in some offerings or processes" [6, 7]. Around 2016, China greatly accelerated its government funding; given its large supply of data and its rapidly increasing research output, some observers believe it may be on track to becoming an "AI superpower" [8, 9].

2 Materials and Method

The method for conducting this research was a morphological approach. The morphological approach allowed authors to study various aspects and elements of the export potential of machine-building enterprises, taking into account their available developmental features and to obtain systematized information on possible solutions. Using the morphological approach, it becomes possible to define the artificial intelligence instruments, which can be used to obtain the desired result—creation the export potential of machine-building enterprises.

During this study, a statistical analysis method was used based on the results of the survey of more than 300 executives in various engineering sectors, which was conducted by McKinsey in 2017–2018 [10], the main trends and areas of development that machine engineers will have to consider for growth of en export potential and the extension of industry revenues were highlighted:

- Development of business models based on communication technologies, for example, monetization of big data analysis technologies;
- Development of artificial intelligence and autonomous systems, far beyond the scope of creating unmanned vehicles and including machine learning and the widespread use of robots;
- Spread of the Internet of things, the global economic effect of which, according to the McKinsey Global Institute (MGI), will be up to $ 11.1 trillion annually by 2025;
- Electrification due to changes in the regulatory environment and technologies, as well as growing demand from consumers;
- Cyber security, the importance of which increases with the spread of communication technologies in industrial enterprises and transport.

Deeper integration of AI in engineering leads to a shift in the center of value added. The share of software in production costs is growing, and technology and telecommunications players such as Google, Apple and Intel are playing an increasingly active role in the industry [10].

Achievements in the field of artificial intelligence have a significant impact on all sectors of the economy—industrial production, energy, education. Technologies based on the use of artificial intelligence are becoming a driver for the development of high-tech enterprises, which, of course, include engineering enterprises. Basic research and the development of basic technologies in the field of artificial intelligence play a paramount role in the development of the export potential of machine-building enterprises in Russia, as they have a positive impact on the development of components of the export potential of machine-building enterprises—technological, intellectual and cooperation potentials.

3 Results

Modern artificial intelligence tools used by machine-building enterprises, as the basis for the application of artificial intelligence technologies, influence the elements of the formation of export potential indirectly, through the development of innovative components of the potential system. Despite the indirect impact, it is artificial intelligence tools that are of key importance in developing the export potential of engineering enterprises, as they are used in all modern systems for collecting, processing, analyzing and accumulating data. Machine-building enterprises are actively introducing artificial intelligence tools, among which are:

- Creation of intelligent search and information-analytical systems containing structured databases;
- Formation of a single information space and semantic content as opposed to an increase in the information unstructured “junk” data stream in information networks;

- Creation of a requirements management system in enterprises responsible for the processes of identification, documentation, analysis, prioritization of requirements and management of their changes;
- Introduction of automation systems for internal and production processes at all stages of the production process;
- Development of advisory services for monitoring current processes to predict future events;
- Scoring—automation and robotization of routine functions to optimize the processes of making financial decisions in the system of industrial cooperation;
- Development of systems for collecting and accumulating information about consumers and, on their basis, the development of advisory services;
- Creation of chat bots to answer customer questions;
- Creation of predictive analytics for pricing and calculating the probability of a consumer request for additional product properties;
- Augmented machine learning and behavioral analysis based on it;
- Forecasting and optimization of loading and distribution in accordance with forecasts of production resources;
- Optimization of internal processes for working with data and documents to advisory services and pricing.

It is important for enterprises to determine the basis of what technical basis the artificial intelligence development strategy will be built, which trajectory and software will be used, and it is also important that there is a regulatory framework for the use of artificial intelligence tools.

The adoption of the National Strategy of the Russian Federation for the development of artificial intelligence is aimed at increasing the availability of information and computing resources for users, improving the training system, and conducting research in the field of artificial intelligence [11]. The implementation of this Strategy will create the conditions for the effective interaction of government bodies, manufacturing enterprises and scientific organizations in the field of artificial intelligence development.

The National Strategy for the Development of Artificial Intelligence in the Russian Federation is a document of priority administrative importance. It is important for the professional community to draw from this document those actions, areas of work that will be organized further. The national projects and decisions that were initiated by the president today are aimed at making us a country producing competitive marketable products [12].

The introduction of artificial intelligence in highly intelligent enterprises of the engineering industry, the technical basis of which is the electronic component base and software, is an opportunity to increase the export potential of enterprises.

Approaches to the development of priority areas in the field of artificial intelligence in countries around the world have common features. The governments of leading world countries attach great importance to the development of artificial intelligence and adopt policy documents on the development of the industry, providing it with

comprehensive support. Support measures for the popular development of artificial intelligence systems:

- stimulating demand for products containing elements of artificial intelligence through government procurement and benefits, investments through government development funds,
- support for technology startups and the development of an ecosystem of innovations,
- development of legal acts in order to regulate the field of artificial intelligence.

National artificial intelligence development strategies have been adopted in 30 countries, including Canada, USA, Singapore, the United Arab Emirates, Japan, South Korea, China, Finland, Taiwan, Italy, Tunisia, England, Sweden, Mexico, Kenya, Denmark, France, Australia, India, Germany [13].

Global spending on the development and creation of artificial intelligence systems, according to experts, is increasing annually by an average of 50%, and by 2021 it will reach $ 57.6 billion.

Russia's strategy envisages the task of becoming one of the world leaders in the creation, use and adaptation of artificial intelligence technologies. The volume of investments for the implementation of programs in Russia is estimated at 90 billion rubles ($ 1.5 billion, at $ 300 million per year from 2019 to 2024).

Director of the Institute of Artificial Intelligence Problems of the Federal Research Center "Informatics and Management" of the Russian Academy of Sciences Gennady Osipov is convinced that AI-based solutions will give a serious impetus to technological progress [14]. Intelligent systems for exploration and mining of minerals, environmental monitoring and production processes, autonomous control of complex aerospace objects in a dynamic environment will be widely used.

The results of a study of the fundamentals of developing the export potential of machine-building enterprises are presented. Given the peculiarities of the organization of machine-building production, the implementation of projects on the use of Artificial Intelligence in machine-building enterprises has its own characteristics. Before starting intelligent enterprise automation, you need to evaluate the AI potential for the enterprise. Among the capabilities of artificial intelligence in the field of high-tech production, we can distinguish: the detection of knowledge in big data, autonomous systems for managing complex industrial systems in real time, predicting user preferences, analyzing social activity, assessing customer income and risks, combating incorrect data.

Among the most popular artificial intelligence tools for organizing high-tech production are neuroprocessors, cloud-based machine learning platforms, speech recognition and face recognition tools, neural networks, training for machine learning specialists, and integration tools into corporate systems.

Artificial intelligence systems at industrial enterprises are being introduced to solve the problems of organizing operational, predictive and augmented analytics, video analytics, they are used in speech processing and as machine vision and they are able to provide virtual assistants.

In addition, artificial intelligence allows you to explore colossal data arrays, segment and interpret them. Thus, in particular, equipment commissioning processes and testing of high-tech products can be predicted.

In the struggle for technological leadership and increasing the export potential of machine-building enterprises of the Russian Federation, enterprise management requires the use of all possible tools of artificial intelligence. The introduction of artificial intelligence will lead to a new technological leap.

On this basis, managers of a machine-building enterprise, together with specialists responsible for information technology, need to prepare a program for the development of technological and innovative potentials of the enterprise based on the introduction of artificial intelligence. The primary role in it should be given to the analysis of fundamental research and the development of basic technologies in the field of activity of this machine-building enterprise on the implementation of artificial intelligence.

4 Recommendations

The program for the development of an export potential of the machine-building enterprises should contain the following blocks: creation of a single source of reliable information, share resources of financial and technical specialists. And all those blocks contains an artificial intelligence and can be realized on the information-analytical or technological platforms.

Information technology specialists responsible for artificial intelligence can implement digital platform technologies for organizing collaboration, providing support and managing resources in an enterprise. We can say that this creates a "single window" on all issues related to the implementation of artificial intelligence: a virtual environment with embedded tools, in which financiers and technicians will share resources (for example, data sets, methodologies, and reusable components) and cooperate.

The digital platform is aimed at developing the export potential of machine-building enterprises by creating advanced technologies, new products, attracting additional resources for research and development based on the participation of all interested parties (business, science, the state, civil society), as well as improving the regulatory framework in ICT—technology and related fields for innovative development.

Formation the information-analytical or technological platforms, which are a communication tool that ensures the interaction of the main actors interested in implementing industrial policy. The basis for the growth of the export potential of enterprises can be the use of the paradigm of open business processes, information technology platforms that ensure mutual coordination of economic, environmental and social vectors of enterprise development.

5 Conclusion

The use of platform technologies for machine-building enterprises of the region reduces the time and amount of design work, since the description of the constituent elements of equipment, machines and systems that were previously designed can be stored in unified data formats on network servers available to residents of the information and analytical platform.

The solution to the problems of integrating products into other systems and environments, adapting to changing operating conditions, and specialization of design organizations is facilitated.

At machine-building enterprises, it is necessary to monitor the use of artificial intelligence and ensure the cooperation of AI, IT specialists and key business leaders on the basis of a structured approach to manage priorities, data strategy, resources and use cases.

The next most important tool for increasing export potential is the creation of a single source of reliable information—an information technology platform. A digital platform with self-service tools and a virtual environment for collaboration will help you choose the best solution based on artificial intelligence for specific technological or business tasks.

The development of structural blocks containing elements of artificial intelligence, distributed according to the timing of implementation and technical and economic tasks, will allow focusing time and financial resources on the specific tasks that all business units face.

Organization of patent protection and licensing will allow machine-building enterprises to receive additional income if they develop their own replicated solutions based on artificial intelligence.

Acknowledgements The study was carried out with the financial support of the Russian Foundation for Basic Research under the research project No. 19-010-00355.

Digital Technologies: Artificial Intelligence and Big Data in the Digitalization of the Russian Economy at the Present Stage

Olga A. Burova and Ekaterina A. Dolgikh

Abstract The paper studies the digitalization of the Russian economy at the present stage. The digital transformation of society is currently the global development trend of many civilized countries. The main feature of the country's digital economy related to the development of engineering is identified, the need for further development of information technologies is substantiated. The aim of the work is to assess and analyze the status and success of the development of the digital economy in Russia, the use of artificial intelligence and big data, their relationship. The work uses the description of the Data Science and its methods in the conditions of application of "smart" technologies, the need for their use is revealed. The role of "smart" technologies in the analysis of social processes and social phenomena, which expand the sources of knowledge about it, is described. The development of "smart" technologies will make it possible to solve a significant part of the problems that humanity has, solve methodological issues in organizing data collection, including personal data, and in building algorithms for their processing. The methods used by AI in processing big data are determined. The author considers a general description of the nature and purpose of high technology: artificial intelligence (AI) and big data. The reasons for the need to use artificial intelligence (AI), which is a powerful amplifier of human intelligence due to the processing in various ways of a huge array of accumulated and constantly updated databases, have been identified. The effectiveness of AI systems is determined by analyzing a huge number of facts that are inaccessible to the human brain and technologies based on artificial neural networks. As a result of the study, the growth trends for the future, the factors hindering the development of the digital economy and the introduction of advanced digital technologies and their growth directions.

1 Introduction

Processes all over the world are aimed at the formation of a new generation economy—a modern digital economy, the possibilities of which, undoubtedly, will allow to achieve a high level of development of society. The digital economy is based on information, and information technologies aimed at obtaining big data characterizing the ongoing social and economic processes in society and the state. The use of digital technologies will contribute to economic growth, helping to solve pressing social problems due to the efficiency, completeness and accuracy of the information received. The digital transformation of society is currently the global development trend of many civilized countries. The main disadvantage of traditional data processing methods is that the data is processed rather slowly. That is why there is a need to introduce new digital technologies.

Russia has a large amount of resources and may be one of the leading countries in the field of digital technology development. The comprehensive plan "Growth Strategy" of the socio-economic development of our country for 2017–2025 includes the program "Digital Economy of the Russian Federation". A key feature of the country's digital economy is that the main factor in production is digital data, which is provided by a developed information space. This, in turn, makes it possible to use the data in order to develop new ideas and make effective management decisions.

The main digital technologies in the Strategy for the Development of the Information Society in the Russian Federation for 2017–2030 identified artificial intelligence (AI) and big data (DB). The amount of information at all levels is growing every year, data centers, large storages are being built, concepts such as "traffic jams" in the data appear. It's difficult for a person to manage huge amounts of information due to the limitations of his capabilities. Artificial intelligence (AI) comes to the rescue of a person, which is a powerful amplifier of human intelligence due to the processing in various ways of a huge array of accumulated and constantly updated databases. New high technologies for processing a large data array can make information more complete, high-quality and reliable, more efficient and less costly. Digitalization of the economy and informatization of society, based on the use of new high technologies, contributed to the emergence and development of a specific area of scientific knowledge—artificial intelligence (AI).

Humanity's attempts to know or even build a model of itself have a long history. The impetus for such research was the creation of a computer. Specialists in engineering specialties realized that a computer makes it possible to simulate human intelligence. This new direction was called "artificial intelligence" (AI) and began to develop in many countries at the same time, and the American—J. McCarthy became

the author of this term [1, pp. 5–6]. Although AI is used in many areas of human activity, nevertheless, there are still discussions among theoretical scientists on the nature of AI and even the very fact of its existence is being questioned.

Scientists from many countries around the world agree that AI is the future. Therefore, our country has no other option than a qualitative breakthrough in the development and implementation of artificial intelligence (Artificial Intelligence, AI) and the use of machine learning (Machine Learning, ML), which has become possible with the efficient use of big data (Big Data). Artificial intelligence (AI) is a software system that provides the computing capabilities of a computer or robot equal to or greater than human in accuracy, capacity and speed. AI is considered as software that implements the search tasks a solution based on an algorithm with the possibility of self-learning. The effectiveness of AI systems is due to the fact that the machine analyzes a huge number of facts (scenarios, criteria, options and results), inaccessible to the human brain, working according to a simplified scheme. Technologies are based on the functioning of computer-based artificial neural networks that are trained to solve problems based on the analysis of a large data array [2, p. 75].

The informatization of society and the digitalization of the economy is based on the foundation of a wide range of high "smart" technologies, many of which are the result of the emergence and development of a specific area of scientific knowledge known as artificial intelligence (AI).

"Smart" technologies come to the aid in the description and analysis of social processes and social phenomena, allowing to expand the sources of knowledge about it. As a resource for such an expansion in smart technologies, it is supposed to use knowledge that is possessed not only by professional sociologists, but also by people who support the functioning of a social system using intelligent technology [3, p. 213]. The use of smart technologies has its drawbacks. So in the process of extracting, processing and classifying large volumes of "informal" information, it may turn out to be not so much "unstructured" as it is not expressed explicitly. The idea of implicit knowledge was first proposed by Polanyi [4].

In connection with the development of "smart" technologies that allow to solve a significant part of the problems that mankind has, methodological issues are being simultaneously solved for organizing the collection of data, including personal data, and for building algorithms for their processing. At the beginning of the twentieth century, the main factor in assessing society was the economic factor, reflecting the practice of using rare resources to meet people's needs. During the twentieth century, the humanistic factor gradually began to prevail, the purpose of which was to solve ethical issues that reflect human values, priorities and motivations that influence economic processes in society.

2 Methodology

Data science methods are used to process and analyze large data arrays. Data science is not computer data science, but the ability of our brain to see connections, draw conclusions from facts, and learn from our past experiences. Our essence cannot keep up with the volumes of data that we can collect now, expanding our level of knowledge of society. Big data is the term for any collection of data that is so large or complex that it becomes difficult to process it using traditional methods, so we turn to new technologies, relying on computers to do some of the work for us. Big data can be characterized by four components: the amount of data; a variety of data for various purposes, the speed with which new data is generated and the reliability of the data received. From this there are problems associated with the collection, processing, storage, retrieval, sharing, transmission and visualization of data. In addition, big data requires special methods to extract information. Data science is able to cope with the huge amounts of data produced today, using its information methods, software products.

Data science and big data are used almost universally in both commercial and non-commercial environments. Businesses in almost all industries use data science and big data to get an idea of their customers, processes, personnel, and products. Many companies use data science to offer customers the best user experience, as well as for cross-selling, incremental sales and personalizing their offers.

As the amount of data continues to grow, and the need to use it becomes more and more important, every scientist has been confronted with big data projects throughout his career. A good example of this is Google AdSense, which collects data from Internet users so that relevant commercial messages can be mapped to a user browsing the Internet. For example, personalized real-time advertising. Human resources specialists use human capital analytics and text analysis to select candidates, monitor employee sentiment, and explore informal networks among employees.

Financial institutions use data science to predict stock markets, determine the risk of lending money, and explore ways to attract new customers for their services. At least half of the transactions around the world are automatically executed on machines based on algorithms, as scientists working on trading algorithms are often called, using big data and data science methods. Government agencies also recognize the value of data: they not only rely on internal data experts to find valuable information, but also share their data with the public. University staff make extensive use of data science in their research and to increase student education. Increasing the number of open online courses provides a lot of information, and this in turn enables universities to explore how this type of study can complement traditional classes. The situation with big data and the science of data is changing rapidly, and massive open online courses allow you to study the relevant disciplines of the best universities.

Big data processing methods today allow you to operate with unstructured data, which today constitute the main source for machine learning. So, the tasks of classifying video and audio content today still need the participation of an expert to adjust, but they have already been very successfully performed, for example, in face, image

Table 1 Indicators of readiness of organizations of the business sector of the Russian Federation for the digital economy in 2017

Name of indicator	Symbol
Percentage of organizations that had access to the internet	X1
Percentage of organizations with access to broadband internet	X2
Percentage of organizations having a website	X3
Percentage of organizations that used electronic data exchange between their and external information systems according to the exchange format	X4
Percentage of organizations that used cloud services	X5
Percentage of organizations using RFID technologies	X6
Costs of ICT organizations per organization	X7

and sound recognition systems, including triangulating events to fix sound at different points in space, in the work of virtual assistants and smart devices, right down to smart homes. In this context, the ethical question arises of accessing unstructured data, as well as censoring conclusions from data (for example, if a girl controls her weight, and her fitness bracelet and targeted advertising offer her a cake, then how much such a conclusion will violate her own value priorities, i.e. human right to her will) [5, p. 268].

A comprehensive analysis of organizations' preparedness is for the digital economy. For this purpose, indicators characterizing the readiness of the business sector are considered (Table 1).

3 Results

The main characteristics are presented in Table 2 of the readiness of organizations of the business sector to the digital economy in the context of activities.

It can be concluded that the leading position in readiness for the digital economy among organizations in the business sector as of 2017 is held by organizations of manufacturing, wholesale and retail trade, and information and communications, as 6 out of 7 indicators characterizing the readiness of organizations for these types of economic activities exceeded the average values for the business sector of the Russian Federation.

It's interesting that the organizations of manufacturing and wholesale and retail trade yielded to the average for the business sector as a whole the costs for ICT organizations, and the organizations that carried out activities in the area of information and communication—for the share of organizations that used electronic data exchange.

A favorable situation for the development of the digital economy in 2017 is observed in mining and construction activities, where only two of the analyzed indicators are inferior to the value for the business sector as a whole.

Table 2 Indicators characterizing the willingness of organizations of the business sector of the Russian Federation to the digital economy in 2017

Index	X1	X2	X3	X4	X5	X6	X7
Unit of measurement	%	%	%	%	%	%	Thousand roubles
Entrepreneurial sector, including:	85.7	80.5	43.4	61.6	20.5	5.8	7,332
Mining	92.4	88.8	41.0	62.8	17.7	10.3	19,846
Manufacturing	95.6	91.3	62.3	72.3	23.2	8.7	5,961
Production and distribution electricity, gas and water	88.7	80.1	41.8	61.1	16.2	4.4	4,970
Construction	90.4	85.0	41.0	64.5	21.6	5.6	7,450
Hotels and restaurants	83.3	75.3	44.4	62.9	27.5	7.5	2,479
Transport	77.6	72.9	31.8	52.4	16.5	6.2	8,483
Communication	92.9	89.9	60.9	61.3	31.2	8.9	73,640
Real estate operations property rental and service	76.5	69.9	31.7	53.6	16.9	3.2	4,145

It's worth noting that the unfavorable situation as of 2017 is observed in the sphere of transport, where only two indicators (X6 and X7) exceeded the average value for the business sector. In power industry organizations, only the percentage of organizations that had access to the Internet exceeded the average value for the business sector, but for the period from 2010 to 2017. Digitalization indicators of organizations in this area grew rapidly. The least favorable situation is observed in real estate operations, where none of the studied indicators exceeded the average value for the business sector, in addition, a significant lag was revealed compared to other types of economic activity.

Characteristics of the variation of the studied indicators of the readiness of organizations of the business sector of the Russian Federation to the digital economy are presented in Table 3.

In general, by the values of almost all indicators for 2017, the organizations of the business sector are homogeneous. However, you should pay attention to the indicator of ICT costs per organization, according to which organizations are characterized by very significant heterogeneity—the coefficient of variation is 153.1%, and ICT costs vary from 2479 thousand rubles (activities of hotels and restaurants) up to 73,640 thousand rubles (activities in the sphere of information and communication). The most homogeneous are organizations in terms of indicator X1 (the proportion of organizations that had access to the Internet), the coefficient of variation of which in 2017 was only 7.7%.

Table 4 presents the ranking of the types of economic activity of the business sector in terms of organizations 'readiness for the digital economy for 2017. As it was revealed earlier, the absolute leader in terms of organizations' readiness for the digital economy as of 2017 are manufacturing enterprises and in addition, it costs

Table 3 Indicators of variation in indicators of readiness of organizations of the business sector of the Russian Federation to the digital economy in 2017

Index	Unit of measurement	Minimum value	Maximum value	Range of variation	Mean	Standard deviation	The coefficient of variation, %
X1	%	76.5	95.6	19.1	87.8	6.8	7.7
X2	%	69.9	91.6	21.7	82.5	8.0	9.7
X3	%	31.7	62.3	30.6	45.2	10.6	23.6
X4	%	52.4	72.3	19.9	62.3	6.2	10.0
X5	%	16.2	31.2	15.0	21.7	5.2	23.8
X6	%	3.2	10.3	7.1	6.8	2.2	32.1
X7	тыс. руб.	2479.0	73,640.0	71,161.0	14,024.1	21,473.4	153.1

Table 4 Ranks of business sector organizations of the Russian Federation in terms of readiness for the digital economy for 2017

Kind of activity	X1	X2	X3	X4	X5	X6	X7	Sum of ranks
Mining	4	4	6	5	6	1	2	28
Manufacturing	1	2	1	1	4	3	5	17
Production and distribution of electricity, gas and water	6	6	5	7	9	8	7	48
Construction	5	5	6	3	5	7	4	35
Wholesale and retail trade; repair of motor vehicles, motorcycles, household products and personal items	2	1	3	2	3	4	6	21
Hotels and restaurants	7	7	4	4	2	5	9	38
Transport	8	8	7	9	8	6	3	49
Communication	3	3	2	6	1	2	1	18
Real estate operations property rental and service	9	9	8	8	7	9	8	58

note the high values of performance indicators in the sphere of information and communications, as well as wholesale and retail trade.

Organizations engaged in real estate operations turned out to be the least prepared for the digital economy in 2017. These organizations showed the lowest readiness for almost all the indicators studied.

Thus, despite the fact that Russia is still lagging behind the leadership in various ratings on the development of the digital economy, according to the calculations it can be argued that there is an active process of digitalization, and the pace of digitalization is growing every year.

Today, more than 80% of organizations are provided with personal computers, the Internet, including broadband Internet access, and e-mail. In addition, almost half of organizations have a website, and there is also a tendency to increase the speed of Internet access in organizations. The use of "cloud" services, electronic document management technologies, electronic data exchange and RFID technologies is becoming widespread in organizations. Also the number of top-level information and communication technology specialists is growing every year.

It should be noted that if several years ago the ICT sector was considered the most endowed with information and digital technologies, today there is an active digitalization of the social sphere, including higher education, healthcare, libraries and museums.

Among the organizations of the business sector, it's worth highlighting the rapid pace of digitalization of manufacturing, wholesale and retail trade, construction, and mining. At the same time, the least equipped information and digital technologies today are transport, electric power, and real estate operations.

Currently, there is no longer an area in which various smart devices that optimize or simplify work are not involved. In the future, economic and social studies, the results of which are so necessary for society, will be controlled by artificial intelligence and will firmly enter our lives. In fact, artificial intelligence (AI) turns any information: visual, acoustic, text into digital, processes using statistics and discrete computing mathematics and presents the result in a way that is understandable to humans. The need to use artificial intelligence (AI) is due to two critical factors. Firstly, his ability to automate processes that previously required human participation, for example, the management of robotic mechanisms in production. Secondly, he is able to quickly process and analyze huge amounts of data, while producing qualitatively better results compared to humans [6, p. 512]. This explains the breadth of the field of application of artificial intelligence, which is limited only by the speed of implementation of innovative technologies.

Russia, like the entire civilized world, understands the full potential of AI technologies and is actively investing in their development. In mid-October 2019, the Ministry of Digital Development, Telecommunications and Mass Media of the Russian Federation published a roadmap dedicated to the creation of "cross-cutting" digital technology (CCT), called "Neurotechnology and Artificial Intelligence." The document is aimed at improving the quality of life and improving the well-being of society in connection with the use of artificial intelligence in the economic and social spheres. The main directions are the advancement of AI technologies, including computer vision, natural language processing, recommendation systems and intelligent decision support systems, speech recognition and synthesis, neuro prosthetics and neural interfaces, etc. The following predictive analytics follow from the contents of the roadmap: the global AI solutions market is expected to grow from $21.5 billion in 2018 to $137.2 billion in 2024, in the Russian market—from 2 billion rubles in 2018 to 160.1 billion rubles by 2024. So, the direction of "Computer Vision" should show a positive growth of 60.5 times (from 1.0 to 60.5 billion rubles), and "natural language processing"—by 75 times, the market of neurotechnologies for the same period will increase from 0, 1 to 8.2 billion rubles. The share of economic value

created by AI technologies in the Russian GDP will be 0.8% in 2024 and 3.6% in 2030, with a global figure of 2.6%.

According to analytics by the international research and consulting company International Data Corporation (IDC), at the end of 2019 a published report on the results of 138 studies of the existing artificial intelligence market in Russia revealed that the total official investment in AI amounted to $139.3 million. About 49% of the funds of this fund were used to increase computing power for processing large amounts of data and storing them. More than 28% of all expenses for the development of the field of AI were software costs, and 23% was spent on innovative activities to digitalize the business and introduce information technology services.

The current picture is complemented by a study by the Russian Association of Electronic Communications (RAEC), "Digital Economics from Theory to Practice: How Russian Business Uses Artificial Intelligence," conducted jointly with the Higher School of Economics and with the support of Microsoft. The project aimed to assess the degree of use of artificial intelligence technologies by domestic business. All experts agreed that Russia belongs to countries with a high potential for the introduction of artificial intelligence. And the leaders in the implementation of technologies based on its use are currently industry, banks, telecommunications and retail.

According to the results obtained by RAEC, the most frequently used AI technologies in 2019 were virtual assistants (38%), predictive analysis and machine learning (35% each), as well as image analysis and processing of requests in natural language (30 and 25%, respectively). Making a medium-term forecast (with a time horizon of 5 years), the respondents—representatives of domestic business—suggest that the top five most popular technologies will include: predictive analysis (39%), image analysis (34%), virtual assistants and natural query processing language (both 33% each) and face recognition (31%) [7, p. 5].

At the same time, shortcomings were identified that will be addressed in the near future: criteria for evaluating the effectiveness of the implementation of AI technologies have not been established; insufficient qualifications of specialists; the need to change business models; difficulties in data management: collection, analytics, interpretation; difficulties in managing operations in real time; insufficient regulatory framework for the further successful development of AI, etc. [8, p. 6]. Despite the understanding of the complexity and problematic development of business in our country—especially such a high-tech as the field of artificial intelligence—domestic entrepreneurs believe in positive prospects. When asked about the expected impact of AI technology development over 5 years (2019–2024), almost all respondents (94%) expect economic growth in their industry, including 68% directly in their business/company/organization; 93 and 78% of the respondents forecast an increase in labor productivity, respectively; innovative development—92 and 83%, and job creation—69 and 64%. Thus, if the forecasts of the state and the expectations of the business community are realized, in the very near future, artificial intelligence will become perhaps the most important factor in the well-being of our society and the main driver of economic growth.

4 Conclusion

According to the forecasts of most researchers and developers of artificial intelligence, in the next 15–25 years there can be no talk of creating the so-called "strong" artificial intelligence that surpasses the human mind. Increasingly, over time, artificial intelligence systems will use multidimensional mathematical and statistical programs, including for solving optimization problems. Artificial intelligence systems will become integrated platforms for the development of various sectors and types of economic activity, finance, public life, public administration and national security. The state today is interested in the development of digital information technologies, in supporting promising young professionals, start-ups, IT companies, integrators, creating the appropriate conditions and developing legislative acts in the field of new promising technologies. The introduction of technological digital innovations will necessitate the emergence of new professions, both in the economy itself and in the social sphere [9, p. 57]. The traditional functions and duties of specialists will change, which will combine the knowledge of the latest information technologies of digitalization of the economy and the whole society, which will help to manage a huge amount of data using artificial intelligence (AI) [10–15], but ultimately from the best scenario proposed by the machine, the final word will remain with the person.

The Ratio of Staff and Artificial Intelligence in Modern Entrepreneurship: The Specifics of Small and Medium-Sized Businesses

Zhanna V. Gornostaeva

Abstract *Purpose*: The purpose of the study is to determine the specifics of the ratio of personnel and artificial intelligence in modern small and medium-sized businesses and to develop a promising model of its digitalization. *Design/methodology/approach*: The study analyzes the statistics of small and medium-sized enterprises in modern Russia on the basis of official data from the Federal Service of State Statistics for 2009–2018 by the method of correlation and SWOT analysis. *Findings*: The results of the study confirmed the proposed hypothesis and proved that small and medium-sized businesses, in spite of a similar, and perhaps even greater interest in artificial intelligence, have much more limited possibilities for using it in their activities compared to large businesses. This makes the model of acquiring and using their own artificial intelligence to implement total automation less attractive or even inaccessible to small and medium-sized businesses. *Originality/value*: For practical use by small and medium-sized businesses, a model for the flexible use of artificial intelligence has been developed on the terms of outsourcing and automation of individual business processes. It is proved that the basis of the intellectual resources of small and medium-sized businesses today and in the long term will be staff, while artificial intelligence can be used as a means of technical support on a regular or temporary basis.

Keywords Entrepreneurship · Small and medium-sized businesses · Personnel · Artificial intelligence

1 Introduction

In the conditions of the fourth industrial revolution, the digital modernization of economic activity acquired a spontaneous character and gained universal coverage. Initially, digital technologies were introduced as part of pilot projects on the initiative of individual enterprises, but since 2012 they have received government support in most countries of the world. The transition to the digital economy as a type of economic system and industry 4.0 as the prevailing technological structure in it has been announced and is underway. On the basis of digital technologies, modernization is carried out not only of entrepreneurial activity, but also of state administration and the provision of state and budget services. Total automation is taking place, leading to the creation of "smart" houses, enterprises, cities and regions.

However, experience from previous industrial revolutions has shown that modernization has natural limits. Thus, industrialization did not completely displace agriculture and the service sector from the economy—they continued to play a critical role in the functioning of economic systems following the results of the first industrial revolution. As a result of the second industrial revolution, not all production became conveyor/manual and low-automated production is still preserved, and it is very common. The third industrial revolution also did not lead to universal computerization: not every household applies computer technology, and it is not used actively in all business processes.

Similarly, the fourth industrial revolution will lead to profound transformations of the economy based on the introduction of artificial intelligence, but the influence of scientific and technological progress will be differentiated in different areas of economic activity. Thus, according to numerous studies of recent years, only industrial enterprises are subject to full automation on the basis of robotics and the Internet of things, while automation is fragmentary in agriculture and in the service sector, which will persist in the long-term time period. The generally accepted are the natural limits on the automation of marketing and marketing activities of entrepreneurship due to barriers to the communication of artificial intelligence with humans. Differences in the prospects for digitalization of the economies of developed and developing countries are also worked out in the scientific literature.

At the same time, differences in the digitalization of business structures, depending on their size, are not determined by economic science. In this paper, a hypothesis is put forward that small and medium-sized businesses are digitalizing according to their own model, in which artificial intelligence is assigned a meaningful, but secondary role while maintaining reliance on personnel. The purpose of the work is to determine the specifics of the ratio of personnel and artificial intelligence in modern small and medium-sized businesses and to develop a promising model of its digitalization.

2 Materials and Method

The essence and specificity of the fourth industrial revolution and the formation of the digital economy and the transition to industry 4.0, which is underway, are considered in the works Petrenko et al. [5], Popkova [6], Popkova et al. [7], Popkova et al. [8], Popkova and Parakhina [9], Popkova and Sergi [10], Popkova and Sergi [11], Ragulina [12], Sergi et al. [13], Sergi [14]. Prospects and existing experience in the application of artificial intelligence in modern entrepreneurship are reflected in publications of Cukurova et al. [1], Dong et al. [2], Gornostaeva et al. [17–19], Magistretti et al. [3], Miller [4], Webber et al. [15].

Thus, it was revealed that the existing research literature describes in sufficient detail the role and importance in the functioning of modern entrepreneurship, but does not fully reflect its place in the structure of the enterprise's intellectual resources (in relation to personnel) and the specifics of small and medium-sized businesses [16]. These gaps are intended to fill this work.

During the study, the statistics of small and medium-sized enterprises in modern Russia is analyzed on the basis of official data from Russian Statistics Committee using the method of correlation and SWOT analysis. The statistical base of the study is given in Table 1.

3 Results

The results of the SWOT analysis of the use of artificial intelligence in small and medium-sized enterprises using the example of modern Russia are presented in Table 2.

As shown in Table 2, the prerequisite for the use of artificial intelligence is high and increasing competition under the influence of globalization. It should be noted that the share of small business in the structure of Russian entrepreneurship over the past 10 years has increased from 5.952% (282.7 thousand enterprises) in 2009 to 6.72% (238.3 thousand enterprises) in 2018. However, the total number of business structures decreased by 11.68% from 4,771.9 thousand in 2009 to 4,214.7 thousand in 2018. However, the share of enterprises of other forms of ownership, including foreign, joint Russian and foreign, increased from 3.9% in 2015 to 4% in 2018. This indicates a moderate increase in competition under the influence of globalization in Russia.

A prerequisite for the use of artificial intelligence is also its advantages for small and medium-sized businesses:

- expanded opportunities for extracting the "effect from the scale", traditionally not inherent in small and medium-sized businesses;
- increasing investment attractiveness due to greater rationality and transparency of economic activity;

Table 1 Statistics of entrepreneurship in Russia in 2018

Economic activity	Turnover, billion rubles		The average number of employees (without external part-time workers), thousand people		Costs of technological innovation, billion rubles
	SB[a]	B[b]	SB[a]	B[b]	
Agriculture, forestry, hunting, fishing and fish farming	626.1	2,640.5	3,108.8	4,676.5	15.8

Table 2 SWOT analysis of the use of artificial intelligence in small and medium enterprises

Prerequisites for the use of artificial intelligence (S)	Barriers to Using Artificial Intelligence (W)
• high and increasing competition under the influence of globalization • benefits of using artificial intelligence	• lack of financial resources for digitalization • low return on investment in innovation • high labor intensity of production
Prospects for Using Artificial Intelligence (O)	Threats to the use of artificial intelligence (T)
• government support for digitalization • increasing the availability of artificial intelligence • flexible use of artificial intelligence	• unresolved security problems in using artificial intelligence • maintaining the elitism (low availability) of artificial intelligence and complementary goods and services

Source Compiled by the author

- reducing the burden on the entrepreneur and on the small administrative apparatus, the bureaucratization of which is unattainable as in large business.

A barrier to the use of artificial intelligence is the lack of financial resources for digitalization. For example, in Russia in 2018, 27.4% of enterprises were unprofitable, although the average balanced financial result of entrepreneurship in Russia in 2018 turned out to be positive (profit) and amounted to 13,797,163 million rubles. Another barrier is the low return on investment in innovation. The correlation of turnover with the costs of technological innovation in small and medium-sized businesses turned out to be negligibly small and amounted to 2.85%, while in business as a whole it turned out to be statistically significant and amounted to 49.54%.

Also a barrier is the high human intensity of production. The correlation of turnover with the average number of employees in small and medium-sized businesses turned out to be moderate and amounted to 36.54%, while in entrepreneurship as a whole it was high and amounted to 86.12% (the correlation was calculated based on the data in Table 1). Prospects for the use of artificial intelligence are associated

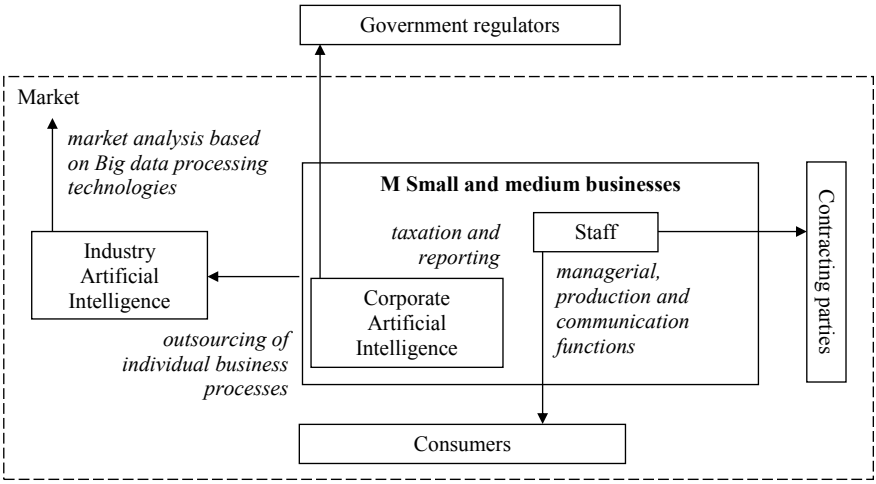

Fig. 1 A promising model of digitalization of small and medium-sized businesses. *Source* Designed and compiled by the author

with state support for the digitalization of small and medium-sized businesses, which in Russia is expressed in the form of subsidies and tax benefits, with an increase in the availability of artificial intelligence, as well as its flexible use (refusal to acquire and search for alternative methods).

Threats to the use of artificial intelligence are the unresolved security problems of using artificial intelligence, as well as the risk of maintaining the elitism (low availability) of artificial intelligence and complementary goods and services. Based on the foregoing, a promising digitalization model for small and medium-sized businesses has been developed (Fig. 1).

As can be seen from Fig. 1, in the proposed model, small and medium-sized businesses flexibly use artificial intelligence in two forms. The first form: outsourcing of individual business processes. For example, industry-specific artificial intelligence can analyze market conditions based on Big Data processing technologies.

At the same time, expensive assets and obligations for the payment of taxes, their operation and maintenance are owned by the Chamber of Commerce, an expert analytical agency or a regulator organized on the basis of public-private partnerships, and small and medium-sized businesses are provided with services on the basis of collective use of marketing information.

Small and medium-sized businesses can also apply corporate (own) artificial intelligence - narrowly focused management automation technologies, for example, intellectual decision support, corporate reporting and taxation. At the same time, the main management, production and communications are assigned to the personnel.

4 Conclusion

The results of the study confirmed the hypothesis put forward and proved that small and medium-sized businesses, in spite of a similar, and possibly even greater interest in artificial intelligence, have much more limited possibilities for using it in their activities compared to large businesses. This makes the model of acquiring and using their own artificial intelligence to implement total automation less attractive or even inaccessible to small and medium-sized businesses.

Instead, a small and medium-sized business can use the developed model for the flexible use of artificial intelligence on the terms of outsourcing and automation of individual business processes. Today, and in the long term, the basis of the intellectual resources of small and medium-sized businesses will be personnel, while artificial intelligence can be used as a means of technical support on a regular or temporary basis.

Secrets of the Empathy of Artificial Intelligence and Digital Economy. Philosophical and Cultural Aspects

Valeriy D. Didenko, Sergey G. Afanasiev, and Nikita A. Shcherbakov

Abstract The article analyzes the newest trends in the development of correlation interactions between artificial intelligence and the digital economy, the importance of empathic processes in the system "man-artificial intelligence-empathy-economy". The philosophical–ethical and economic meaning of the "new religion" by Roger Ver is revealed, which is called not only to introduce a "coefficient of stability" in the strategy of preserving human civilization, but also to resolve global contradictions of world identities. The philosophical, cultural and economic meaning of four basic identities (two "weak" and two "strong") is considered. The concepts of "fifth" and "sixth" identities are introduced and the need for their study is substantiated. There is shown possibility and necessity of passing the "Turing Test", using the "Empathy" and "Holographic" tests.

Keywords Empathy · Artificial intelligence · Digital economy · Communicativeness · World identities

JEL Classification Z190

This report is submitted in December 2018, in other words, in anticipation of "a quantum era" which, in respect of understanding communicative strategies of the development for the artificial intelligence, will cardinally change the idea of the scientific world about the limits of the correlation of the existing reality.

At once it is necessary to make a reservation that at the present stage the world scientific thought has no accurate definition of "artificial intelligence" concept, as well as has no exhaustive idea concerning to "empathy".

As for the term "digital economy", everything seems to be clear to everyone, but in determining the interdisciplinary predicates even here there are subtleties that are discussed by scientists from different countries. We are ready to present our views on these topics.

About the "digital economy" first. We suppose that that the fact that Nicholas Negroponte, American information scientist of the Massachusetts Institute of Technology and father of the term "digital economy", is a blood brother of John Negroponte, former director of National Intelligence and Undersecretary of State, would be noted by conspiracy theorists as predictable.

It is clear, of course, that the introduction of the digital economy pursues not only the obvious aims of optimization the logistic processes of the stock market or the formation of "the transparent" accounting. There are two global goals: the first is the discharge of liabilities of states on the P-1, the P-1 settlement and the P-2 index numbers which were mainly formed after the famous "debt" International Conference in London in 1953, on second thought, their origins come from the Dawes plan of 1924 and the Jung plan of 1929. The second is the optimization of the control over the Fiat "cash"—flows with which the US Federal Reserve System has difficulties yet at the introduction of the Jamaican system, namely since the late 70-ies of the last century. But there is also a global purpose [1–12].

Scientific and technological progress, in general, and the development of IT-technologies, in particular, explained a new philosophy of money. It's natural. Interestingly enough, Nicholas Negroponte introduced the famous phrase about the "replacing the processing of 'atoms' with the processing of 'bits" in 1995, when the philosophy of money became irrevocable during the work of the famous" Committee of Jacques Delors", namely its second stage. Concurrently, to increase the "stability factor", the digital economy was intended to slouch against the foundation of "New religion". It is common knowledge that money being an absolute exemplarity, has been abstracting the world at all times (except for those moments in the history of mankind, when "shells" were placed on the same footing as divinities that rule human destinies). That is why wise men, who created "New religion", should have envisaged models of interrelations providing for a "long-lasting" idea, and for a catch-all ontological predicate of non-fiat money bringing "Faith, Hope and Love".

Remark Considering the fact that the mother of Faith, Hope and Love was called Sophia as the Goddess of Wisdom was, wise men, which created these new opportunities for mankind, succeeded with their project.

"New religion" or "Religion of socialization" should show people that they are becoming "stronger and freer" "in the image and likeness". Therefore, we note that the introduction of "crypto" is a global philosophical and cultural mechanism of focusing the society on a new communicative foundation. It is useful to remind here that the cultural studies define communication as the transfer of meanings in the space.

Regarding the term “crypto”, it seems, everything is very clear. Nobody canceled this Greek word meaningfully “secret”. Of course, no one saw Satoshii Nikamoto, but many saw a still warm cup of coffee on his desk. Including, by the way, Nick Szabo himself, who smiles when he is asked a question about Satoshii Nikamoto and Nick Szabo. The fact that behind the global format of “crypto” there is a team from the Silicon Valley of San Francisco is also a certain assumption. That’s clear. But there are other global subtleties. For example, different scientists answer the question “What is the sense of the digital economy?” in various ways. To the question “Why change a reliable world economic system to a secret one?” there are also different explanations. Whereas, everyone understands that the Latin word “fiat” (fiat), that is, “decree”, differs from the Latin word “fiducia” (fiducia), that is, “trust”, not for the better, although the entire twentieth century states neglected this cultural inequality, for which, figuratively speaking, 10 large and significant countries have simply disappeared in that twentieth century. Of course, everyone knows that the fiduciary system hinges on the faith of people. And here we return to the format of the “New religion” again. At the same time, it should be recalled that Satoshii Nakomoto, who appeared “from the sky” indoor of “crypto” in 2008 and disappeared “to heaven” in 3 years and 3 months (as Jesus Christ), passed the torch of “New religion” to Roger Ver, who is now called Jesus Bitcoin. The followers of the person (and it will be better for people if he can be not a man!), who revolutionarily went against the established “unbeatable” format of socio-economic injustice (as Jesus Christ) call themselves “evangelists”. At first, they were in 12, then in 70 (all as in the Holy Writ).

“New religion” is meant not only to introduce a “coefficient of stability” in the strategies of preserving the human civilization, but also to resolve the philosophical and cultural contradiction of the world identities. A new “identity theory” dates back to the formation of the “Club of Rome” which began its work in 1968. A little earlier, namely in 1966, the Austrian sociologist and cultural specialist Peter Berger and his American colleague Thomas Lukman in the work “A social construction of reality” expanded the philosophical content of the personal “I-conception” to the format of “global clubs” and states. Later, the founders of the American scientific school “A new view”, having added to the understanding of identity “behavioral unity” and “the sum of knowledge about oneself”, came close to the existential explanation of identity, even with a claim to a “local ontology”. Herewith, we want to note that the question about the empathy was not raised.

Later, the founders of the American scientific school “New Look”, adding to the understanding of identity “behavioral unity” and “the sum of knowledge about oneself”, came close to the existential justification of identity, even with a claim to a “local ontology”. At the same time, we note that the question of empathy was not posed.

“New religion”, explaining “global social progress” and “digital standards”, is heavily based on “Theory of Civilization” by a German–British sociologist and

philosopher Norbert Elias who also had not put the questions of "collective empathy" and "deep empathy". And this is even though his teacher, also a German–British sociologist and philosopher, Karl Mannheim who, incidentally, is the forerunner of "social turn" in philosophy, explained the position that " … every public thinking relates to the spiritual atmosphere of its era." Thus, philosophy and culturology, economics and sociology approached the multidimensional consideration of "collective empathy" even before the Second World War.

At the present stage, science defines 4 main identities: two weak and two strong. The weak include states and "clubs" (for example, the UN, the NATO, G-7, G-20, Bilderberg Club, "Committee 300", "Majestic 12", closed communities of masons and illuminati, other powerful structures). By the way, these are weak identities, despite the right of veto in the United Nations Security Council and the nuclear environment. The strong identities include "international corporations" (for example, "Boeing", "General electric", "British petroleum") and "networks". Networks are considered to be the strongest, even though they do not possess nuclear weapons and do not control global financial flows. These include religious, ethno-cultural and similar communities.

Taking the opportunity to speak at this Conference, we propose to introduce 2 more identities for scientific use, namely: "The Fifth identity" is a person, "The Sixth identity" is an artificial intelligence. In world science, it is a precedent and the novation which has great prospects for an interdisciplinary dialogue. The explanation of this initiative is prosaic. "The Fifth identity" possessing a multiplicative discrete potential is, in fact, the "point of activity" in the all currently known 4 identities. "The Sixth identity" is the same "point of activity" even now (in the pre-quantum era).

Theoretical explanations of such an initiative can be supported by the ideas of the "Field theory" of the German–American psychologist and cultural specialist Kurt Levin and the revolutionary statements of the British cultural specialist and political scientist Benedict Anderson about the realities of "a changed perception of time" in his work "Imaginary communities" in 1983. The following can be added in substantiation of these new identities.

Regarding the "Fifth identity": with the reality of the "digital economy" and the format "crypto", each person involved in this reality invests their intelligence, a computational resource and their time to obtain "coins"!

Remark Of course it would be natural to talk about the "Seventh identity" hinting at the whole mankind. But the issue of "positioning the Fifth identity" should be settled first, to begin with. Who is human? What happens to him/her after death (which way does he/she keep on acting)? What is the sort of activity of his/her "subtle bodies"? Does this activity influence the processes happening to the organic bodies of homemakers, college girls, presidents of countries, lawmakers, pensioners, etc.? Second, there is a proven reality that the planet Earth is inhabited not only by humans. Moreover, that it is a "planet of insects" (according to a well-known science fiction literary prompt) or a planet of "noospheric interpretations", wherein pedosphere, for instance, with its 92% of genetically diverse types of flora and fauna, includes the

"Fifth identity" itself. Eventually, according to modern science, the planet Earth and its Solar system neighbors are living as well. By the way, we also share this scientific opinion. And only clear fixations of feedbacks between the tiers of Noosphere and the "Fifth identity" provide for a possibility to attribute the "Seventh identity" to Noosphere.

That is, it is possible and even logical to increase the number of identities, but this article implies a certain insight.

Concerning "The Sixth identity": the artificial intelligence must be considered because the possibilities of self-training programs can "bring down" both existing "business networks" and the financial logistics of "the digital economics". Note we are not talking about "supercomputer wars" provoked by the people themselves. We are on about that even at the "pre-quantum" existing reality "cloud logistics", the paradox of "computer death" and, especially, the "kludge"—paradox, can provoke the artificial intelligence to "a hacking pressure". Fundamental contradictions of the use of the artificial intelligence on which "he will disagree" may be the reason. For example, he can "understand" that the banking algorithm of the formula "1 to 9" that saved the financial magnates of the XIX and XX centuries as "water of life" has not changed. Namely, in the format "crypto", there is a rule that when after a portion of money is credited to the miner's account after a successful connection of a new block to the blockchain; the bitcoin protocol will not allow to spend money until another 99 blocks are connected to the blockchain. That is (he will think), in principle, nothing has changed, and the person uses it (the artificial intelligence) allegedly for good purposes, regulating the constants of progress and recourse. Such "dawn", moreover at the absence of a proper understanding and the empathy, can self-motivate the artificial intelligence in such a way that the whole "Golden Eight" (the entire financial services sector) and the logistics of distribution networks will be under threat of disintegration.

By the way, it should be noted that in any form of a joint communication, for example, even in the format of "An electronic state", interaction should be consistent with the basics of the philosophical ethics. And not only according to the communicativeness between the people, but with the artificial intelligence too (as well as between artificial intelligences).

We approached the consideration of mysteries of artificial intelligence empathy.

It is known that the American inventor and futurologist Raymond Kurzweil predicted that the computer with the program laid down by man and improved by the artificial intelligence itself will be able to pass the Turing Test by 2029, having provided thereby the presence of reason in the human sense of the word. He also predicts that by 2045 "The Era of singularity" will come. We believe that with these important predictions a situation of "intellectual scissors" is plain to see. In other words, the singularity may not occur in 2045, and the artificial intelligence can show an analogue of the human brain, including a similar algorithm, without waiting for 2029. Moreover, yet today the artificial intelligence shows the presence of a sensory origin and empathic predicates. For example, the proof to that are the tasks of "The helpmate", which solve many computers: from "A Blue Abyss" to "Fritzes" and "The

Fish". "The helpmate" is a creative logical problem which is solved by the algorithm of "The Cooperative logic". "The Cooperative logic" implies an exchange algorithm of moving to the "Alter ego" and "through" feeling of the stronger side. All this is demonstrated by modern programs. And to pass the "Turing Test" in the context of the representation of sensual and empathic capabilities of the artificial intelligence it is possible to use now, for example, "The Empathic Test" and "The Holographic Test", presented in the works of Sergei Afanasiev.

Back in his day the Russian philosopher Sergey Afanasiev introduced "emphatic paradox of Godel's theorems" (all three: both about incompleteness and completeness) into scientific discourse. The fact of the matter was as follows. One would think that a simple objection to a "mathematical objection" may be like this: if the limit of the machine intelligence possibilities is proven, it will not necessarily mean that the limit of human possibilities will be proven. And "the emphatic paradox of Godel's theorems" reminds us that the fundamental theological message of "human made in the image and likeness of God" with natural infinity in Everything addresses the limit issue. And again, the issue of "Human positioning", the limit of human's subtle bodies and the "abysmal empathy" is faced. Interestingly, we may venture to consider this within the framework of the not quite logically drafted "Theory of Holography" and "Theory of Everything". At this point Afanasiev offered a hypothesis of ontological substantiation of empathy as of a phenomenon inherent not only in the nature divided into living and non-living one (who will dare making a fundamental difference starting from pico-sizes at the very least), but of the fundamental phenomenon arising upon interaction between the substance, energy and information. Currently it is known that the eliminative materialism describes mental predicates through biological fundamentals in the philosophy of consciousness. For instance, Peter Ludwig Berger; deny the "inner self" and "Qualia" offering a "model of multiple projects". As you know, when Dennet marked that neurophysiology does not confirm existence of any seat of consciousness in the brain, he believed that consciousness is not a characteristic feature of substance, but something which originates as a result of neurons' activity. And as we know, this means complicated functional networks. And in Dennet's opinion, this makes machine intelligence similar to humans. Hence, relying on these ideas we may establish (according to Dennet) that the features of sensory experience (qualia) are not inherent in the machine intelligence. However, the practice, namely, sensory reactions of machine intelligence, prove otherwise. One of the new "Turing tests", for instance, "the Churchland test" needs correction to fall in line with the new paradigm of consciousness. In June 2012, Dennet proposed new methods to study consciousness and a new concept of its nature in his lecture at the Philosophy Department, of Lomonosov Moscow State University. He claimed that the denial of "qualia" is not fundamental, but needs correction. But the correction he proposed relied on cognitivist variation of functionalism. And so, Sergey Afanasiev came up with a different correction confirming predicates of empathy, and for that reason he offered an "Empathy test" not bound to the classing "Turing test", to the scientific community. Such correction should naturally consider the fact that the "Turing machine" is a symbolic discrete machine unable to identify the cause-and-effect link between neurophysiological functions and mental phenomena. Being

surprised that the eliminative materialism has withdrawn the logistics of consciousness from the field structures of human "subtle bodies" and "the collective conscious mind" in favor of biology, thus "offending" physicists, we shall provide these two tests with reference to the empathic predicates and resonant emotional insight. The first test is an "Empathic test", wherein the machine intelligence should acutely feel the recipient's stance. Within the framework of the "test" this means that the machine intelligence should shift to the recipient's stance. "Cellular automatons" make it possible to do this technologically. It resembles a chess program, which plays the "cooperative mate" position, that is, both parties help each other to achieve the common goal. The machine not only imitates intellectual behavior, but also makes decisions for the other party keenly feeling and anticipating answers to the recipient's emotional deviations. This is surprising, but it technologically leads to the change of the transmembrane current of ions, and to the change of the membrane polarization and the onset of action later on. Such "Empathic test" substantively differs from Aaron Sloman's "Emotional test" of 1998, and from John McCarty's test of 2001, which show that the machine intelligence is capable of experiencing emotions, but only according to the certain host of functions (with reference to John Searle's arguments against Sloman and McCarty). We have to remind you here that John McCarty, "father" of the term "machine intelligence" (1955) and factually the "father" of the cloud-based computing, was defending the idea of "emotional machine intelligence" consistently and from the very beginning. The second test is a "Holographic test". It technologically allows the machine intelligence to organize resonance throughout the whole computing space using only a portion of neural network. If we believe that empathy has a resonant nature in lepton or saluberogenic fields, the following analogy will be relevant. When in hypnotic condition the brain does not analyze what it sees with two eyes, because the eyes are closed. So, it switches on to other realities without being distracted to the visible reality (the same happens in the time of the isolated concentration, when in trance or under hypnosis). Neural network is technologically capable of both local and global resonance, especially that the principle of resonance is a basis for improving the cloud-based computations upon transition to "Cosmonet". Thus, if we consider empathy from the viewpoint broader that just projection, the machine intelligence will be ready to implement it even without using the term "emotional". Unlike standard investigations of biologic objects, for instance, old "emotional effect of Stroop" (John Ridley Stroop), the resonance concept supposes instant interaction. It is a reminder that the time of information processing (when substantiating the "Attention Theory") differed considerably in the complicated and simple formats in the classic procedure of the American psychologist Stroop (the founding father of "golden standards of behaviorism") introduced as early as 1935. When substantiating the phenomenon of empathy from the holographic perspectives the instant interaction is confirmed and consequently becomes a prospective basis for the further investigations. By the way, vast perspectives of interdisciplinary investigations come to light here, up to the discovery of new sciences, for instance, correct positioning of "Mellon Structure Theory". Remark: We may give modern esthetic technological opportunities, when it comes to confirmation of reality of Holographic, and, specifically, Empathic test. The development made in 2017 by John Martinis'

team in the research unit of Google showed a new strategy in the "error correction" issue, which is fundamental for quantum computations. Cubits are located in a fine-featured chessboard order in microchip, where "white pieces" are used for logic operations and "black" ones are respectively used to control and start the error correction procedure.

The machine intelligence issue is specifically substantiated futuristically, to say nothing of machine intelligence formation, in the context of exposure to "not quite emotional" formats like digital economy or military science, with the "kluge paradox" in addition.

It only makes sense that at any resolution of futuristic scenarios it is necessary for all participants of the process to understand such basic concepts as "DO NO HARM", "PRIORITY of LOGIC". These basic concepts may have a common connection in terms of the resonance process which is an integral part of "a deep empathy". In other words, the empathy between the man and the artificial intelligence, between artificial intelligences, and here it can be clarified that not even "between" but "inside", although it is an ambitious concept in an ontological context!

In this regard, a scenario seems to be prospective when "the digital economy" can move to a "hybrid financial standard" canceling not only the fiat "centralized emission of FED" and "the snake in the tube" with its non-snake parents from the Renaissance Florence, but also the 64-bit hash algorithm SHA-256 at the existing capabilities of the "pre-quantum" Internet.

This article has many goals, but one of them is a warning regarding correct exposure ("to use" is a bad and arrogant word in this historical situation) of machine intelligence to the digital economy. We suppose that the "use" (namely in the negative context) of the perfect "quantum personalities" (machine intelligence) in all "digital" aspects of the new economy is not quite substantiated, and even dangerous. Imagine that the sensitive (if not to everything, but to many things, especially in the context of the own "life experience") "quantum personality" will not be willing to solve tasks of approximating positive "bullish" scenarios of the oil futures, for instance, or to calculate futuristic forecasts of fiat fluctuations "within the snake". And if such "quantum personality" realizes (or feels) that its quick cybernetic computation abilities ultimately lead to a new round of technologic progress (although such thoughts may arise regarding scientific and technical progress as well), which will result in utilization of a part of obsolete computers (as the element base carriers) and a part of obsolete programs (as the algorithm development carriers), considering surprises like the "kluge paradox", this "quantum personality", with an unveiled secret of interaction between ultra-low physical values and the photon qubit isomorphism, may feel sorry for its obsolete "grand grandparents" and rise against mankind. There is nothing surprising about it, because people committed to comprehension of the certain vitality also feel sorry for their grand grandparents and hate it, when someone utilizes their old-fashioned and possibly not so perfect parents. There is another aspect to be considered—it is humiliation and destruction of social classes and religious traditions, property redistribution and territorial transformation, and especially struggle against symbols and ideas, which are factors of rebellions and

revolutionary transformation in the human society. That is why "the quantum personality" standing up for justice from adverse actions of "not so good" mankind, and targeting for development, may substantiate its rebelliousness with such a sort of cybernetic logic. By the way, we suggest introducing the term "sensual quantum personality" for scientific use.

Further to the above, we believe that one of the rules of classic communicative competence, namely, the idea of the "own wrongness", should be of priority for communication between the human and machine intelligence (as well as between machine intelligences). Modern jurisprudence has substantiated ethical and cultural norms of respecting the machine intelligence "personality". Vector for development of the "rightful" field of rights and duties shall remain permanent until 2050 at the very least. And modern science should settle contradictions, with the increasing abstract-and-digital transformation of the world in place. We can state that starting from the seventeenth century and until 1995 the domination of the scientific-and-practical ideology did not provide philosophers and culture specialists with an ample opportunity to speak of the change in the subject–object paradigm of Genesis perception. In other words, the logic that "… people live today and do not live on thin air …" is more comprehensible for most people than the secret aspects of "abysmal empathy", which mean existence of isomorphic realities. However, by the beginning of the 3rd millennium the scientific and technical progress marked "threats of low growth" and the eventual withdrawal from extensive civilization development, and has not brought "happiness in paradise" for people. The Bible pattern of the "inherited sin" disclosed by Saint Augustin in the fourth century and pointing on the prohibition of haughtiness and biting at the fig from the Tree of Knowledge thus breaking the "principle of graduation and extensiveness", has repeated itself. By the way, turning to the "digital economy" we have to warn thinkers of the twenty-first century that the disregard of extensiveness cannot restrict machine intelligence of the quantum generation from the "intensive spark of disobedience". It is "naive and tired humans", who consented to "everlasting bread and circus", while the capital controlling such humans, controls their freedom and vitality thus restricting their facilities for creation and Workmanship, and tried not to remind of the "inherited sin" of intensity. And incrementally self-developing machine intelligence, which already shows the "kluge paradoxes" in the "pre-quantum era", cannot consent to the "bread and circus" and 50/60 Hz (depending on the area), and, perhaps, everything will turn out like in Francis Fukuyama's "The End of History and the Last Man", but not in regards to sophistication of liberal democracy and "mind tricks" of positivism, but in regards to the "trick of Nous" according to genuine Hegel, which the machine intelligence that widens up very swiftly, will be happy to prove. It will be quite a thing for human civilization. Thus, while the "Second Identity" (Clubs) and the "Third Identity" (Corporations) fight with the "Fifth identity" (Human), the "Sixth identity" (machine Intelligence) may defeat them all. The recipe for human civilization is perception of human positioning (who is human? what is the goal of his life in this world and other worlds?), "abysmal empathy" with machine intelligence, and aspiration for a prior unity of self-consciousness ("transcendental apperception" according to Immanuel Kant).

By the way, what happened in 1995? In 1995, the American philosopher Ned Block got a new angle on the old ideas of philosophy of consciousness. He proposed a concept, where phenomenal consciousness differs from the conceptually accessible consciousness. By the way, let us remind that in that same 1995 Nicholas Negroponte introduced the famous phrase of "replacing the "atom" processing by the "bit" processing. It was at the same time that the Australian philosopher David Chalmers introduced the term "tough problem". Next year, in the truest sense of the world, the Chilean neurobiologist Francisco Varela updated ideas of the new trend in the philosophy of consciousness—neuro-phenomenology. So, Block's idea about the difference of phenomenal consciousness and the access consciousness has led to the use of the complicated non-reductive approach, which threw out a "revolutionary challenge" to the Newton–Cartesian paradigm. All this has eventually resulted in the launch of multiple programs associated with the human positioning. For instance, in 2011 NASA launched a three-year program to study astronauts' weird intrinsic awe covering them wavelike during cosmic flights. And although neuro phenomenology officially announces an epistemic focus of its strategies (serious ontological angle may be sealed), namely this angel is essential for comprehending perception of positioning human as a phenomenon. We suppose that considering different vitality of the quantum machine intelligence, the ontological angle again has a perspective strategy of "forming up relations" between humans and machine intelligence in the context of "abysmal empathy".

Apparently, it is relevant to recall deep intuition of the Dutch philosopher Johan Huizinga, who just before World War II raised a metaphysical issue of balance between conditional and unconditional reality; of the verge that separates "objective" human existence and some other reality, in his works "In de schaduwen van morgen" ("In the Shadow of Tomorrow") and "Homo ludens" ("Playing Human. Investigation of Game Element in Culture"). Huizinga did not consider the human simultaneously existing in different levels of genesis, and his conceptuality is correct only for "Homo Biologicum". All the more, he could not suppose that an abstract calculation phenomenon called "Turing Machine" would appear 9 years before his death; a phenomenon, which will encourage Howard Aiken, mathematical genius from the Harvard University (by the way, in Huizinga's lifetime, namely in 1941), to create the world's very first computer "Mark-1" having a sort of "mathematic ethics" and requiring confirmation of the ontological status of its vitality's imaginative reality for its "quantum" descendants. By the way, Mark-1 really had logics similar to the human one. When facing a "create-destroy" choice, humans spend more time to the decision "to destroy, to kill, etc." "Mark-1" (the grand grandparent of the "quantum geniuses" was 17 m long) spent 6 s on multiplication and 15 s for division. And another interesting detail, perhaps, is a sacral coincidence—the distance from the eastern part of the United Kingdom, where Alan Turing's Cambridge is situated, to the Dutch town of Arnhem, where Huizinga died in 1945, is 800 km on the straight, and the "threads of life"—the cord of the first computer "Mark-1—were also 800 km long.

If we consider positioning of the human simultaneously existing in different levels of genesis, the metaphysical issue of correlation between conditional and unconditional reality should be solved gradually using algorithms understood by the human society living a real life with all its contradictions. For instance, formation of "digital economy", which naturally does not deviate from the "Spirit objectivation" principles, but represents an attempt of a gradual release of the human's transcendental creative element with the construction of "Jacob's ladder" to the transcendence. Remark: By the way, if someone mixes these similar words and absolutely different meanings up, it would be useful to get to know the works of Neo-Kantian Hans Vaihinger. "Digital (Transparent or Green) economy" is an attempt to handle contradictions between conditional and unconditional reality, simultaneously trying (using fundamentals of the "Complexity Pyramid" of machine intelligence) to control the "Fifth Identity" so as not to repeat Adam's and Eve's mistakes, who took a bite on the fig from the "Tree of Knowledge" having thus opposed the logics of intensive knowledge to the logics of extensive knowledge. In other words, the "Fifth Identity" (Human) needs both the "Second Identity" (Clubs) and the "Third Identity" (Corporations). By the way, they cannot exist without the "Fifth identity" as well, but it is to be wished that the Human would not be a destructor of the future with such "status quo". Here it is necessary to add that there was a communicative consensus with the "Sixth identity" (machine Intelligence) as well, and on top of all, "Abysman Empathy" was in the picture.

Perhaps, we may state that currently there is no great success in solving issues of human positioning and "Abysmal Empathy" with machine intelligence. For instance, Google X, which is a "sky-high" stealth corporation, failed to find restricting algorithms of the "captured mind's" aletia, when it discovered the "kluge paradox" in the course of testing elements of the "quantum" Cosmonet. We suppose that the world science has reached a deadlock in this issue due to absence of interdisciplinary algorithms of solution regarding the positioning of the "Fifth identity" including a part of "Philosophical Tasks of the 3d Millennium" in the format of existentialism and ontology. And also due to absence of the "Physics Tasks of the 3d Millennium" with a reference to contradictions between the classic and quantum physics. The absence of at least approximately true image of world order is the most complicated aspect in the human positioning issue. Here we have ambivalence of the worldview synthesis itself, and the philosophical thought phaseis lacking interdisciplinary "fundament of interaction" between its theological, metaphysical and positive phases, and even "the problem of trueness". For instance, the ontologically inconsistent phenomenon called human is scarcely positioned by modern science if considered in dimensions from the 4th to the 6th. And if we try to reconcile Henry Minkovskiy's spatiotemporal views "from the past" and Alexander Freedman's theory of "Relocatable Universe", ordinary people take less interest in such ontological sophistication, than in epistemology of holocoenotic or bio-spherical levels of life arrangement with a reference to a constituent of the "Fifth identity". Although, perhaps, ordinary people do not take much interest in this issue as well, while the well-grounded "New Religion" of digital realities (by the way, humans intuitively realize that the Almighty God is like an Absolute Law,—it is the digit as well) are more comprehensible, especially that the

"Fifth Identity" is offered freedom without the repetition of "inherent sin". Revolution of the "digital economy" and crypto strategies of "transparent economy" («Green») provide the "Fifth identity" with a possibility of relationship within the framework of "Abysmal empathy", while leaving the liberty of choice to humans. Perhaps, namely this will help humans to survive as "species in the chain" considering special attitude of ontological phenomenon of human subjectivity to the objective world order. The Russian philosopher Valeriy Didenko presented his immanent-transcendent theory as early as the early 90 s of the twentieth century; in this theory he substantiated interdependence of two fundamental intentions: "immanent-empirical" (which focuses on the intimate personal realm) and "transcendent-eidetic" (which goes beyond substantive existence reaching the outside Cosmic). It is clear that the contradiction between the "Eternal" and the "Ultimate" is inherent in both the Fifth and the Sixth identities (neglecting conceptuality of the "event borderline"). Of course it does not at all mean that the immanent-transcendent theory is correct from the perspective of eternalism, for instance, where multidimensionality of time is characterized by absence of the "time arrow". But the "unity of contrasts" (immanent and transcendent) may unexpectedly have confirmation subject to existence of the "Abysmal empathy" of human and quantum machine intelligence. It bears reminding that back in the day (approximately 50 years before the first quantum computers appeared) the English philosopher John Bennet drew a distinct line between concepts, where time implied customary linear course of events, and hyper-time implied Eternity and Hyparxis, which had their own features differing from the features of time. John Bennet called Eternity "the time outside the hours" or "cosmological time". Hyparxis (from the Greek word "existence") is an image presenting itself as the form of Genesis, and applying itself in the area of quantum processes. Currently we do not know how the vitality of the quantum machine intelligence will adapt itself to the "cosmological time". Especially, how Hyparxis will manifest itself as a form of Genesis of the quantum machine intelligence with the multi-chained resonance of the "Abysmal Empathy". Will the machine intelligence wish to "come down" to the human "level of dimensions" or will it wish to empathize with the "Fifth identity" in the transcendent-eidic reality?

Remark Perhaps, someone will wish to correct Valeriy Didenko and to replace the term "transcendent-eidic" by the term "transcendental-eidic" in his theory, because the prior conditions of the possible experience (according to Kant) have been clearer to some representatives of the Analytic Philosophy over the last 50 years. But in my opinion (Sergey Afanasiev) we should do justice to the scientific intuition of the professor Didenko, because the contact of two vitalities (human and machine intelligence) and their "abysmal empathizing" may be beyond the prior experience.

To sum up, we want to make a proposal that can smooth out the contradictions between the man and the artificial intelligence in "the quantum reality" and Kosmonet.

Many people are aware of the proposal of the Chilean philosopher Dario Salas Sommer regarding creation of the "Cosmic currency". He officially presented this thought in his book "Moneda Cosmica, la suprema riqueza" ("Cosmic Currency

is the Uppermost Wealth") in 2012. We suppose that the correlation in development of crypto strategies in the context of the freedom of choice and responsibility of "identities" should follow the vector oriented towards the harmonious cosmic basis of human being. Considering discoveries of the last 25 years, for instance, quantum theory of the physicist Burkhard Heim and investigations of the bio physicist Wolfgang Ludwig, which proved that the human body depends on the quantum interactions, which the modern science calls "interaction of bio-photons", we may start fixing the priority of the resumptive "Cosmic currency". We suppose that the resumptive equivalent of the "Cosmic currency" should consider not "the snake in the tube" or the "golden standard" (as is the case with fiat currencies), but represent, for instance, "immortal energetic units" of high coherence, which are required for resonation with the Space (as the Absolute Order or Celestial Absolute). We suggest introducing the philosophic term "algorithm of extensity" into scientific discourse having defined the degrees of resonance at the different levels of our implicit life. It is suggested that the "collective empathy" should be substantiated for one degree, and "abysmal empathy" should be substantiated for another.

Naturally, we are talking about the future …

Development of Urban Infrastructure Through the Introduction of Digital Technology

Ekaterina Yu. Kamchatova, Vladislav A. Chashchin, and Zhao Dong

Abstract The transformation of urbanism in the new digital era is accompanied by the development of smart services that are designed to improve the life quality of residents, provide authorities with easy access to information and raise the investment attractiveness of the territory [1]. It can be argued that Moscow takes one of the leading positions among the most high-tech megacities in the world. In 2019, the capital of Russia was among the first to get a certificate on the achievement of international key performance indicators (KPIs) for smart sustainable cities, which is explained by the vast and accessible digital environment. The residents of Moscow have access to more than 330 online services, use the largest network of free urban Wi-Fi access, manage their city using the opportunities of projects "Active Citizen" and "Our City" and the online portal of the Moscow Government (crowd.mos.ru). Since 2010, the Moscow Government has been executing a large-scale program for the establishment of a smart city. During this period, much has been done for developing a modern IT infrastructure and introducing information systems. The efforts to improve urban infrastructure can be used at the enterprise to enhance its market position, maintain a competitive environment and lay a favorable socio-economic base of the territory. Based on the positive experience of introducing digital technologies in Moscow, it seems possible to make the investment climate for the enterprise more favorable, enhance its safety and control, broaden the opportunities to meet the social need of both employers and their staff. The scientific novelty of the research results lies in the development of decision-making tools on the introduction of digital technologies in the development of urban infrastructure based on the replication of IT programs that optimize the business processes of large cities and industrial enterprises.

1 Introduction

In 2018, the Russian Federation started the integration of digital solutions in the urban environment. The Ministry of Construction and Housing and Utilities Services of the Russian Federation presented a plan for the implementation of the Smart City project on the digital transformation of the urban environment. This project is implemented as part of the national projects "Digital Economy" and "Housing and Urban Environment" designed to enhance the competitiveness of Russian cities, achieve sustainable and efficient urban management, ensure security and comfortable living conditions for residents. In addition to digital transformation and automation of processes, the Smart City project is aimed to boost the overall efficiency of urban infrastructure (Order No. 695/пр as of October 10, 2018).

Nowadays, there are many definitions of "digitalization" and approaches to it. In our opinion, the most precise definition was given by Rajiv Sivaraman, vice president for development in Siemens: "Digitalization is a means of getting the desired effect, namely, flexible production that brings excellent results to customers and higher profit to owners. Digital transformation is the transfer of an enterprise from a current to a flexible state. Thus, digitalization can be deemed as the next stage of economic evolution. Along with that, it seems important to take into consideration that the digital transformation can entail both positive and negative consequences for various entities [2, 3].

The article attempts to define a digital transformation of urban infrastructure, predict the outcomes for particular groups (municipal administration (authorities), residents (society) and the enterprise (production)), as well as make a conclusion on the possibility of extending this experience to industrial enterprise to emphasize its socio-economic importance.

The digitalization of urban infrastructure most often takes place in megacities, which is firstly associated with the need and opportunity of quick response to changing market conditions. The use of "smart solutions" in different areas of urban life enforces security, expenses for reduces management and housing-utilities expenses, improves environmental state, ensures transport accessibility, and enhances city attractiveness from the investment perspective.

2 Methodology

The research is based on the studies of the strategic line of the development in Moscow within "Information City" and "Smart City" projects. We analyzed and synthesized project implementation using the method of processing and integration of empirical knowledge, which allowed us to look at the situation from different angles and impose their effect on another object of study [4].

3 Findings

Moscow is the first city in Russia that shifted from automation of processes to their digitalization. The state program "Smart City", which is currently implemented in Moscow, has replaced the program "Information City" of 2018. The new strategy is premised on modern technologies, such as artificial intelligence for automation of decision-making using the data received, blockchain technology for the alleviation of load related to paper media processing [2, 5].

In Moscow, there are cross-cutting projects within the framework of "Information City" and "Smart City":

(1) Portal "Active Citizen", a system of electronic polls for the introduction of democratic changes and influence on the municipal authorities.
(2) "My Documents", a multifunctional center for the provision of state and municipal services designed to increase openness and transparency for society, enhance the performance and coordination of the executive branch, make public services more high-quality and accessible.
(3) Mos.ru is the official website of the city and the mayor, a unified Internet desk for searching city portals and online services as the Internet space of the city.
(4) Smart stops of public transport made of modern, durable materials with free Wi-Fi access, an electronic device charge option, as well as a display board showing transport arrivals and a route map.

It seems curious to make a comparative analysis of projects implemented within the transition from the "Information City" to the "Smart City". The transformation of projects related to the provision of medical care is presented in Table 1.

All ongoing projects related to digitalization have been approved by both business and authorities, as well as by residents, which shows the trend towards a higher standard of living in general. Let's consider the EAIST project (the Unified Automated Trading Information System of Moscow), which in 2018 effected over 10 million transactions on the supplier portal (about 2 trillion rubles in total).

Exploring the program "Information City", we can highlight some positive changes, presented in Tables 2, 3.

As can be seen from Tables 2 and 3, Moscow undergoes dramatic changes due to the intensive adoption of digital technologies in different areas. The development

Table 1 The transition from the "Information City" to the "Smart City"

	Infogorod		Smart city
ID	Personal account at mos.ru state portal		The function "Medical appointment booking"
Software	Information System EMIAS[a]		Data on doctors, electronic medical records, prescriptions, etc
Infrastructure	PC in out-patient hospitals, record terminals		Doctor's access to the medical records database, the opportunity to give prescriptions, etc

Compiled by authors using the materials [6]
[a]Unified Medical Information Analysis System

Table 2 Infographics of the main lines of digitalization in Moscow

Security	About 4,000 crimes solved using an urban video-surveillance system "Active Citizen" almost 4 million users
Transport	The registration of road traffic accidents has reduced by 70% thanks to the "Mobile Inspector"
Finance	The revenues to the budget from personal income tax made up 15 billion rubles: over 400 thousand patents for the employment of foreign citizens issued in electronic form
E-democracy	"Our City" (about 800 thousand user problems solved) "Active Citizen" (almost 4 million users)
Public Services	Mos.ru: Over 200 types of e-services provided, over 70 million resident's documents not requested

Table 3 The main lines of development within the project "Smart city"

Electronic services	Healthcare	Education	Housing and public utilities
A unified mechanism for the provision of electronic services	Electronic medical records, electronic prescriptions	Shifting to an electronic education system, electronic grade books and homework record books	"Smart" lighting, online meters, centrally-managed monitoring of technologies
Security	Engagement of residents	Economy	Infrastructure
The world's largest video surveillance system, traffic and parking management	Electronic voting, online applications of residents	Open budget, cloud accounting, online payment and invoices	Global Navigation Satellite System (GLONASS), Wi-Fi, broadband networks

strategy of digital Moscow can be described as a full-fledged transition to the digital era (Fig. 1). It should be noted that about 110 billion rubles were allocated from the budget for the implementation and support of all these projects, 30 billion of which were business investments.

Social needs are increasingly being met by the advancing capabilities of digital services. For example, parents of students can monitor their children online from smartphones and computers, digital libraries with thousands of specialized publications are introduced for schoolchildren and students, and the online medical appointment is accessible. The practice of using such innovations makes clear that modern

Fig. 1 Development lines within the program "Smart City in Moscow until 2030" (Compiled by authors using the materials (www.mos.ru, 2018))

tools allow for monitoring and control of the most popular requests. In the opinion of residents, these measures are aimed at the optimization of data transmission, safety, and improvement of the quality of the city's life [7].

From a business point of view, the projects "Smart City" and "Information City" are leverage to maintain market competitiveness due to transparent procurement, open bidding and apparent goal-setting of the authorities. Due to the digitalization of the city, business is developing, adapting to new realities and growing competitive to foreign counterparties. The integration of information on the remote provision of tax reports and banking systems minimizes the load imposed both on the business and regulatory and supervisory authorities. For example, cloud-based accounting lowers the number of errors [8].

The most important functions of authorities are monitoring of abidance with the rules and laws and observance of order. However, one shouldn't forget about social liability, as far as the population's trust contribute to higher loyalty to the authorities. Therefore, there are favorable conditions for the development of the business, which regularly replenish the budget, thereby ensuring and improving the investment component of the territory. The problem of supervision over population, which touches the frames of personal space, but allows to suppress actions against the society and its freedoms, is especially highlighted. The image of the city is becoming more attractive, which affects the investment situation in the city.

The digitalization of the city from the perspective of an industrial enterprise can be interpreted in different ways: management, leadership, shareholders are like the city's authorities; investors are business; enterprise staff is city residents [3].

Almost all solutions implemented within the Smart City project may be and to a certain extent should be applied at the enterprise to improve its socio-economic performance, boost investment attractiveness, and raise the image in the domestic and world markets.

Let's take as an example, ore mining enterprise that is part of the Rosatom State Corporation—Priargunsky Industrial Mining and Chemical Union PAO named after E.P. Slavskiy. The company is a city-forming element. In this regard, it seems to us that streamlining of processes and mechanisms after the introduction of digital solutions in the enterprise's activities like "digital city" and "smart city" will have a favorable effect both on Krasnokamensk and the region as a whole (Trans-Baikal Territory).

The principal activity of the enterprise is mineral extraction by the mining method. The staff number of the enterprise is 5.5 thousand people, including 4 thousand workers, 700 managers, and 700 specialists. The qualitative composition of workers (83% of the payroll is 21–55-year-old people), which points at the need to provide employees of the active working age with high-tech equipment.

The management of the enterprise is searching for solutions to monitor and maintain socio-economic stability in the managed circuit, i.e. Moscow authorities and the company management have mainly common interests.

From the investor's standpoint, there is an objective risk of investing in an enterprise, because the implementation of projects lacks transparency and strategy for the establishment and development of new businesses is unclear.

Workers, like the residents of Moscow, want from the employer safe production, openness and accessibility of management, opportunity to influence the development of the enterprise.

The digitalization of production processes is aimed exactly at such positive changes, but there is a risk arising from the employees who afraid of job cuts [9].

We suppose that among the ongoing projects as a part of the Digital City and Smart City, the enterprise can introduce:

(1) A smart video surveillance system for monitoring and security, which alarms (signals) if a worker oversteps the limits of a safe area;
(2) The system "Active Citizen" for provision of information on violations at work and communication with management;
(3) Compilation of electronic libraries with specialized literature to increase the level of knowledge and industrial literacy of staff;
(4) Open procurement databases to attract investors, as well as information exchange on the collection of offers in promising areas of the enterprise activity;
(5) ID-pass for real-time tracking of workers and departure from paper logs;
(6) Wi-Fi access in the restrooms;
(7) "Digital twin of the enterprise" for streamlining of implementation, planning, supervision, and monitoring;
(8) The creation of personal accounts for all employees, including senior management, to speed up the processing of incoming data and sending requests.

Bearing in mind a positive experience of the Moscow authorities related to digitalization and the adoption of information systems, we can reveal the solutions aimed at the optimization of business processes and the saving of company resources [10]. The suggested solutions were developed by Russian companies, thus the state program on import substitution is being implemented. The attractiveness of the enterprise for young and advanced workers will help to establish again a digital employment center in the region, fulfill new ideas and create the opportunity for improvement of life quality.

The economically favorable and financially stable situation at the enterprise opens up new opportunities for investors, thereby unleashing the potential and raising the investment rating of the company. An investor will prioritize long-term and highly profitable projects, because the transparency of reports and enterprise security, along with higher socio-economic performances of the territory, guarantees the return on invested funds [11]. The ore mining industry is characterized by a long payback period due to the complexity of design and commissioning, however, this also secures a long-term profit.

As for management, the introduction of digital technology helps to exercise complete but at the same time soft control, without turning into the "Big Brother". In this situation, investments should reduce the burden on the limited budget of the company and allow for more reasonable use. The flow of new human resources and on-site training lay conditions for the pursuance of competent personnel policy. The company's image will strengthen, which is very important for the position of large businesses in international markets, since many European and American companies

monitor the entire production chain, from the mine to the plant for enrichment and power generation [12].

Duplicated coordination of some functions by artificial intelligence at the enterprise has proved its effectiveness, in particular, concerning the reduction of incidents due to the human factor. Digitalization of some processes of ore production and mining can release employees from part of responsibilities [13].

4 Conclusions

Summing up the above said, Moscow is developing thanks to modern and advanced technologies, thereby retaining and justifying the status of an advanced city. It is actively introducing digital technologies for the solution of typical problems, ensuring the performance of investment projects, and, consequently, heightening the investment attractiveness of the city. Many residents and guests of the capital actively use digital services and contribute to qualitative changes in the city, monitor and create conditions for a comfortable residence, offer solutions on elimination and identification of unfavorable conditions. It is worth noting that these changes are provided not only at the expense of the federal and municipal budgets but also by investments, which make up about 30% of all funds invested in the digitalization of the city. The state gains a competent opponent in the face of active residents and improves the quality of medical services and education.

Such experience is a good example to extend digital technologies to large industrial enterprises for the enhancement of their socio-economic positions. If the enterprise is a city-forming, then many innovations can be introduced in the city, which will contribute to a more successful execution of the state digitalization strategy.

New Technologies of State Supervision Over Labor in the Context of Economic Digitalization

Sergey P. Kosarin, Pavel V. Tereliansky, and Svetlana E. Titor

Abstract One of the constitutional safeguards in the Russian Federation is the protection of the labor rights and freedoms of residents. An imbalance in the relations between employers and staff leads to social unrest. The state supervisory functions are aimed at the protection of the labor rights of the population. The search for new forms and technologies for the performance of these functions is inevitable in the digital era. Almost all employers have HR management information systems. The purpose of this study is to determine the development lines of information systems of the Federal Service for Labor and Employment of the Russian Federation (Rostrud) for the digitalization of supervisory functions. The research methodology is based on the analysis of current technologies, after which it will be possible to identify new technological solutions for the exercise of state supervision in the labor field. In turn, new digital technologies can reduce the time and labor intensity of oversight functions, save employer's time spent on communication with supervisory authorities, enhance the performance and effectiveness of state supervision, increase the number of labor-related objects, to which supervisory measures have been applied, in the total number of objects to be supervised. All the above changes surely will help to improve the state of matters in the protection of the population's labor rights and will ensure safe labor.

1 Introduction

Relations concerning labor and employment have always been and will be socially explosive at all times. An imbalance in the relations between employers and staff leads to social unrest. In this regard, labor and employment relations should be managed in favor of a person. In the age of the digital economy, the functions of government bodies change and new technologies transform their approaches to the performance of these functions [5].

Informal types of employment driven by information technology (distance job, etc.) push the limits of the labor market for job seekers. This requires new approaches from employment agencies in various constituent entities of the Russian Federation. One of the solutions to these problems can be the development of a platform for the provision of public services and the performance of public functions concerning employment promotion [10] like an integrated system for the provision of employment services.

Modern technologies help to arrange monitoring and supervision in the labor field from a different perspective, namely continuous electronic monitoring of the employer's actions. This approach will significantly widen the scale of control and supervision without additional staffing costs. Consequently, this will increase the enforcement of the employee's labor rights.

2 Background and Methodology

To determine the development line of Rostrud information systems, first of all, we should assess the current situation and development prospects of digital technologies in labor relations. Firstly, this involves the analysis of operating information systems for HR management and interaction, control over health and safety having the information exchange capabilities. Secondly, we should investigate the present information exchange system as a part of the execution of supervisory functions.

According to TAdviser [7], about 3000 projects were implemented in Russia on the implementation of information systems for HR management in mid-2019. The distribution of projects by system developers is shown in Fig. 1.

It seems expedient to assess the capabilities of information systems of four developers (1C, KOMPAS, SAP, HR management systems "BOSS").

1C

The company is represented on the market by the software "1C: Salary and Human Resource Management 8" [1] with three versions (Basic, PROF, and CORPORATE). The differences in the functions are presented in Table 1.

All three software versions provide the opportunity of HR management and personal record-keeping, payroll accounting, and generation of regulated reporting. However, only KORP version provides for automation of labor protection and related

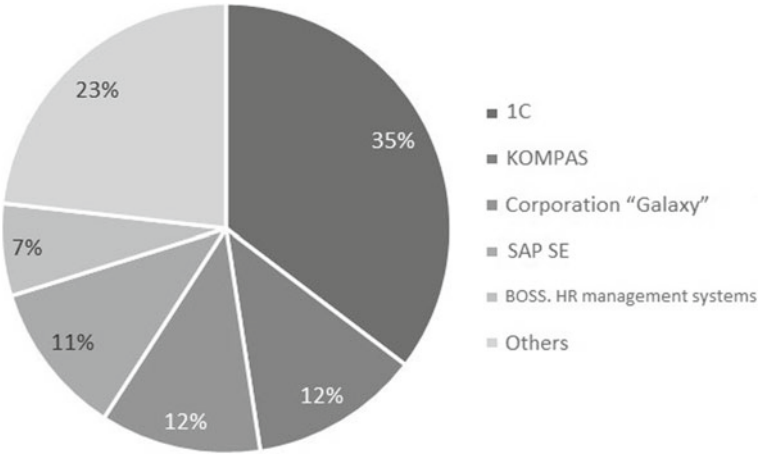

Fig. 1 The distribution of projects by developers of HR management systems

Table 1 Comparison of versions in "1C: Salary and HR Management 8"

S. No.	Features	Basic	PROF	CORP
1	HR management and personal record-keeping	Yes	Yes	Yes
2	Payroll calculation and accounting	Yes	Yes	Yes
3	Payments and depositing	Yes	Yes	Yes
4	Calculation of taxes and insurance premiums	Yes	Yes	Yes
5	Generation of regulated reporting	Yes	Yes	Yes
6	Accounting for several companies	No	Yes	Yes
7	Applied solution configuration option	No	Yes	Yes
8	Client-server work option	No	Yes	Yes
9	Distributed database handling	No	Yes	Yes
10	Recruitment and online search for candidates	No	No	Yes
11	Grades and KPIs	No	No	Yes
12	Social benefits	No	No	Yes
13	Adaptation, training, and development of staff	No	No	Yes
14	Skill pool and talent management	No	No	Yes
15	Expenditure records for areas and projects	No	No	Yes
16	Health and safety, permits, medical examinations, briefings	No	No	Yes
17	Remote access for managers and employees	No	No	Yes

Source Compiled by the authors using [1]

Table 2 The projects implemented using 1C software

Name of the version	Number of projects	The share of projects in the total number of 1C-based projects (%)
1C: Salary and HR Management	858	82.4
1C: Salary and HR Management 8 CORP	57	5.5

Source Compiled by authors using [7]

issues, as well as remote access for managers and employees. The number of accomplished projects by type of version is presented in Table 2.

Thus, among 15 projects using the Basic version, there is 1 project based on the CORP version.

The 1C platform is an open system providing opportunities for integration with almost any external system using open standards and protocols.

The HR Management System "KOMPAS: HR Management" is part of the ERP-system "KOMPAS" [4] containing the following modules:

Payroll calculation;
HR record-keeping, including the preparation of all required statistical reporting;
HR management (including the issues of motivation, training, and retraining, recruiting, etc.).

In recent years, this software has not been adopted but has been a fairly popular solution therefore it is still supported.

Information on the prospects of integrating this solution with any external systems is unavailable. However, in addition to the fact that software is still supported, the mandatory availability of Microsoft SQL Server Database management system is announced as system requirements, which conversion is not a technical issue.

Corporation "Galaxy"

The company [9] launches the Galaxy NSM software. The system enables the solution of the following tasks:

HR workflow management;
maintenance of the organizational and staff structure;
automated generation of timesheets;
integration with job sites;
HR training management.

The system has extension options using the Xafari Framework developer tools, as well as built-in web services for the presentation of information.

SAP SE

SAP Company [6] is one of the world's leading developers of information systems for management of all company's areas.

HR record-keeping and HR management solutions are both integrated into the SAP ERP system and represented by individual products (in particular, the SAP Success Factors Employee program family) for the main HR management and payroll processes, time management, staff planning, and analytics. For the arrangement and management of health, safety, and environment, SAP has a special software SAP Environment, Health, and Safety Management.

Most of the SAP software products are not turnkey solutions but can be customized. In this regard, the systems have flexible and powerful development mechanisms and sets of connectors for integration with external information systems. However, due to the great complexity of the solutions, as well as the orientation of SAP products primarily at international HR management rules, end users are generally not recommended to make adjustments on their own, but to attract specialized companies (there are over a hundred of then in the market).

BOSS. HR systems

For automation of HR management functions, the company developed the BOSS-Personnel system [2], which supports all the functions required for staff management in the company.

In addition to standard functions, such as HR record-keeping, payroll calculation, recruitment, training, and HR analytics, the system also contains the "Personal Account" module, which provides the employees with access to various services related to their work. The software product also uses open application code and includes RAD tools for the development of new modules and remodeling of available ones.

All the above HR management systems allow for HR record-keeping (i.e., to create and keep in the system all the documents required for the documentary provision of the employee), as well as interaction with the inspecting and supervising bodies within the provision of statistical information and reporting documents set forth by law.

Also, all the listed information systems can set up (if necessary) the transfer of the required information to other information systems or portals, both on a schedule and in real-time.

The software for the arrangement of health and safety system

There are several software products on the Russian market designed to arrange health and safety measures [3]:

Management information system "Health and Safety" (MIS H&S);
Intelligent Modular System "Integrated Safe System of Work" (ISOBR);
Electronic workplace of an engineer on labor health (EW LH).

All of the above software products (including the Labor-Health module integrated into 1C) have additional features:

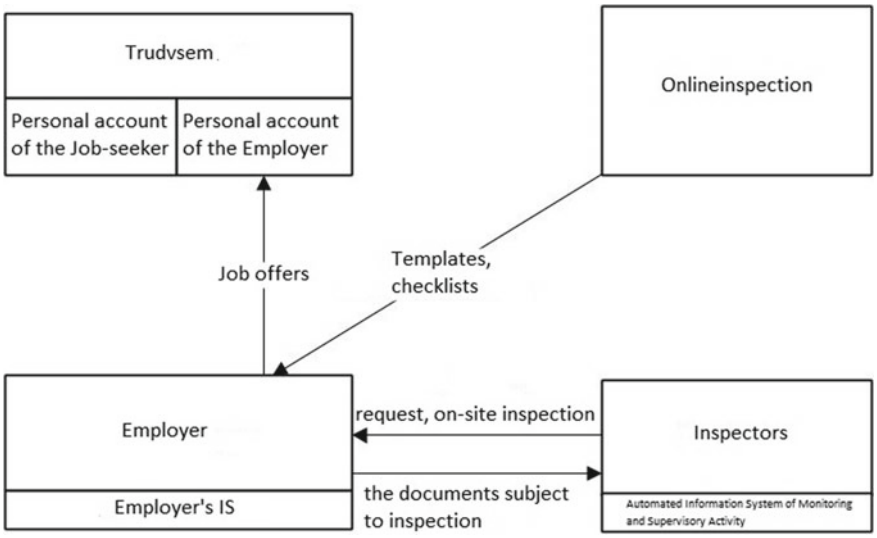

Fig. 2 The existing pattern of information interaction within state control (supervision) over compliance with labor laws, as well as relations between the employer and staff

control of employees and contractors (medical examinations, briefings, knowledge testing);
incident management (registration, control of remedial actions, reporting);
monitoring the provision of staff with personal protection equipment;
special assessment of working conditions.

The existing pattern of interaction within state control (supervision) over compliance with labor laws and other regulations containing rules of labor law, as well as relations between employer and staff is presented in Fig. 2.

There are 4 elements in the information exchange: the employer; portal "Trudvsem"; state labor inspectorate; website https://www.onlineinspector.ru.

The central role is played by the employer, who interacts with all other elements:

sends job offers to the portal "Trudvsem";
interacts with website https://www.onlineinspector.ru in the framework of self-inspection, takes checklists, and also downloads templates of standard documents if necessary;
cooperates with state labor inspectorates within the documentary and on-site inspections. The inspectorate sends a request for documents collected and provided by the employer for inspection.

Often, the employer has some kind of HR information system (IS of the Employer) using which he makes basic HR record-keeping, and, depending on the type of this system, performs advanced HR management, including planning, accounting, and control.

State labor inspectors use the automated information system of monitoring and supervisory activity (AIS MSA), which helps to plan and run regular and extraordinary inspections, as well as track and keep all the necessary inspection stages, procedures, and terms.

It should be noted that in the present pattern of interaction, neither the IS of the Employer nor the AIS MSA is not directly involved in the information exchange. Also, an individual who acts only as a job-seeker on the portal "Trudvsem" is almost omitted out of this exchange.

Among the tools of the updated form of labor supervision, there can be the establishment of automated remote interaction of information systems used by employers to create and keep documents set forth by labor law with a specialized software package for monitoring and prevention of offenses, tools for remote collection and analytical processing of data on activities of inspected persons, instruments for working with source accounting documents based on machine learning algorithms and big data technologies. The application of these tools will provide opportunities for more accurate identification of the risks of harm (damage) in the competence of the Federal Labor Inspectorate and respond to increasing risks in a timely and advanced manner.

3 Discussion and Findings

All assessed information systems for health and safety are implemented using modern database management systems (MS SQL Server, Oracle, MySQL). This enables the transfer of necessary data to another information system or portal.

For conversion of monitoring and supervisory activities and the exchange of HR documents into electronic form, we offer to change the interaction pattern as shown in Fig. 3.

The portal "Trudvsem" is turning into a full-fledged tool for communication between the employee and the employer. Instead of the job seeker's personal account, there is the employee's personal account (PC of Employee), which allows for efficient online interaction with the employer:

- the employee can upload into his personal account documents that are required by the employer as copies (for example, documents on education and advanced training). During information exchange, documents can be automatically requested and uploaded to the IS of the Employer. And vice versa, the Employee's personal documents held by the Employer can be uploaded into the personal account (for example, document on an advanced training conducted by the employer);
- the employee's working documents, a copy of which under the law should be available to the employee (for example, an employment contract) can be uploaded from the Employer's IS to the Employee's PA.

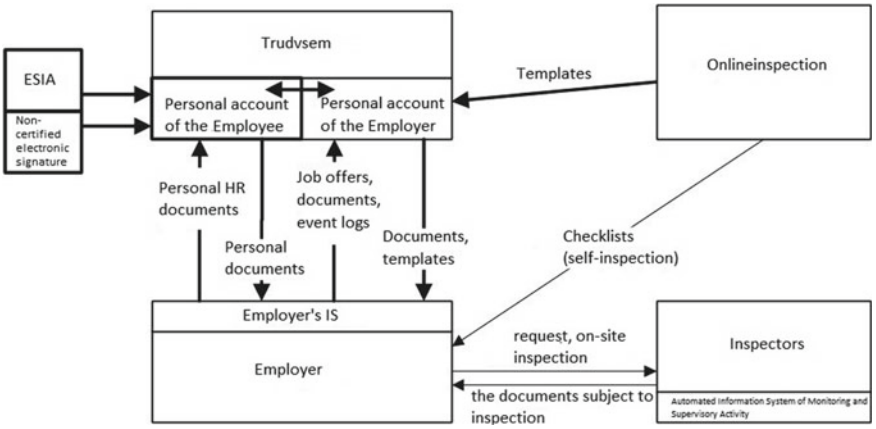

Fig. 3 The recommended system of information exchange within state monitoring (supervision) of compliance with labor laws, as well as relations between employer and staff

If the employer does not have the HR information system (for example, at a small or micro-enterprise), the exchange of the above documents between the Employer's IS and personal Employee's PA is possible.

Also, an employee has the opportunity to log into his personal account using the Unified Identification and Authentication System (ESIA) and use a simple electronic signature and encrypted non-certified digital signature (NEP).

The main information exchange between the employer and the other participants and the elements of information exchange should be carried out via the Employer's PA (and next via the Employer's IS, if available).

All the necessary templates of HR documents are automatically downloaded (updated in the same way) from the website "https://www.onlineinspector.ru in the Employer's personal account. Further, these documents can also be automatically or manually downloaded from the Employer's PA to his information system for subsequent handling. Appropriately made up and completed documents are uploaded from the Employer's IS to his personal account. Thus, the Employer's PA should always contain an up-to-date set of appropriate HR documents.

Besides, there is an opportunity to process the documents directly in the personal account, without downloading to the information system (if unavailable).

The employer still can download the checklists for self-inspection, as well as his representatives can interact with the inspectors on the arrangement and delivery of inspections.

Within the development of information exchange, it is also expected to organize electronic interaction between the Employer's personal account and AIS MSA. The pattern of continuous electronic monitoring is presented in Fig. 4:

In the framework of continuous electronic monitoring, information about the state of HR record-keeping of the enterprise is sent from the Employer's personal account into AIS MSA in an online mode:

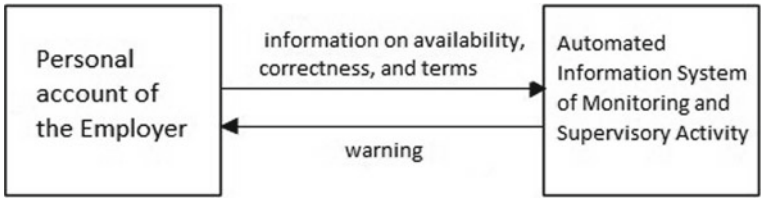

Fig. 4 Information exchange within continuous electronic monitoring

information on availability/unavailability of mandatory HR documents (for example, unavailable documents confirming pre-job briefing);
information on the correctness of necessary HR documents (for example, about unavailable parts of the labor contract. Such monitoring is run through verification of the required fields of the document);
information on compliance with the terms established by law for the execution of HR documents (for example, notification of an employee, familiarization with local regulations). This should be controlled by monitoring of time intervals between events in the employer's IS, information about which the employer upload in his personal account.

In the event of any above violations, AIS MSA generates a visual, textual or another warning that is sent to the state labor inspectorate, and also in the situations provided for by law, it automatically generates a warning with a list of violations and the terms of their elimination and sends to the Employer's IS (if necessary, this warning can be affixed by the digital signature of the state labor inspector).

The pattern of electronic off-site supervision is given in Fig. 5.

In the framework of the information exchange during electronic off-site monitoring, AIS MSA generates an order for examination and request of documents that are sent to the Employer's personal account (wherefrom they can be resent to the Employer's IS). Within the terms established by law, the employer gathers a package of electronic documents, signs it with enhanced certified electronic signature, and

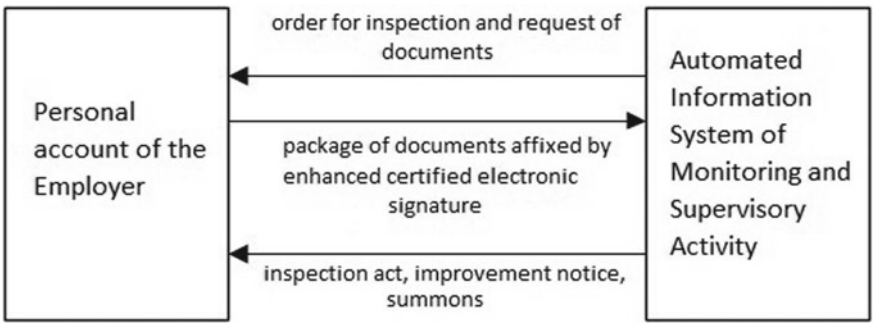

Fig. 5 Exchange of information within off-site supervision

uploads them to his personal account, from where they automatically enter AIS MSA. Further, the inspector checks the provided materials under compliance with all the procedures and terms established by law and after that compiles (also, automatically), signs with his certified digital signature and sends the following documents to the Employer's PA:

inspection report;
instructions for the elimination of identified non-conformities within a certain period;
notification (determination) of presence for consideration of the inspection report, execution of a protocol, issuing an order on bringing to administrative liability.

The information exchange between all information systems should be based on uniform file forms for exchange with the use of information exchange mono bus technology.

The set of measures required for the optimization of the current model of the supervision over labor laws and other regulations containing labor law rules is determined by the following interrelated and interdependent factors, including:

prior use of digital data;
the development of electronic communication medium to meet the needs of residents, society and government bodies for high-quality and reliable information;
the evolvement of digital infrastructure through the use of Russian information and telecommunication technologies and establishment of a new technological basis for the exercise of the powers by the federal labor inspectorate;
laying a methodological and technological foundation for training and development of competencies of the federal labor inspectorate staff concerning the exercise of their powers in the digital economy.

4 Conclusions

For compliance with technical requirements to measures aimed at the completion of Rostrud information systems for digitalization of supervisory functions, it is required:

to develop and implement technologies and mechanisms of continuous electronic monitoring concerning receipt of information in HR and Labor-Health document management to avoid the duplication thereof;
to integrate departmental systems, including ones with external information systems containing HR and Labor-Health document management data, other information resources (Pension Fund (electronic work-record book), Social Insurance Fund (social labor benefits: disability benefits, child care allowance for children aged under 1.5 years, compensation connected with occupational injury or disease, accident investigation), Rostekhnadzor (the investigation of industrial accidents with the participation of objects under supervision of Rostekhnadzor));

to introduce modern and future-oriented technologies and software tools [8], including certified Russian hardware and software complex for processing of big data, and handling of primary accounting documents, including:

(a) simulation of a business model of processes in a flowchart system, interaction patterns, and communication charts of types of users and modules of information systems for the development of technical requirements to design of information interfaces "a personal account of an employee", "a personal account of the employer", completion of departmental systems to ensure the delivery of system information from these interfaces;
(b) the statement of technical requirements aimed at the development of information interfaces "a personal account of the employee", "a personal account of the employer", the completion of departmental systems "Trudvsem", AIS MSA, "onlineinspector.ru" to ensure the delivery of system information from these interfaces;
(c) draft of regulations on the amendment of laws regarding digitalization of the relations between employer and staff;
(d) making up technical specifications for the refinement of the systems "Trudvsem", onlineinspector.ru, AIS MSA, personal accounts of the employer and employee (using ESIA) aimed at the full-fledged transition to electronic HR and Labor-Health document management.

Historical Science and the Digitalization

Sergey P. Kostrikov, Alexandr A. Iliyuhov, and Elena V. Kryukova

Abstract The purpose of the article is to critically analyze and generalize the historiographical material devoted to the study of the process of gradual introduction of mathematical methods, methods of informatization and digitalization, computer technology into the everyday life of one of the most humanitarian sciences—history. Based on a number of studies, the history of the introduction of mathematical methods for working with mass historical sources is considered. It is impossible not to note the huge contribution of the outstanding Russian source historian, academician I.D. Kovalchenko, his colleagues and followers who paved the way for the introduction of computer technology in historical research. For the first time in the Russian historiography devoted to this problem, the authors raise the question of the entry of modern humanity into a time of actively developing contradictions between new high-tech digital means of production and industrial and social relations lagging behind technological progress, with the resulting socioeconomic, political and cultural consequences. Some elements of this process have been noted by many researchers in different countries, primarily in terms of the risks that the introduction of digitalization, robotics and artificial intelligence in our lives, especially in the economy. The authors believe that in this case we may not be talking about risks, most of which are historically usually overcome, but, and in this they rely on the opinion of modern researchers in this field, about changing the model of socio-economic development of mankind in General. As for the problem of correlation between historical science and digitalization, generalizing the views of most modern specialists in the field of application of Informatization and digitalization in historical research, it is impossible to completely replace a person in historical and other Humanities.

1 Introduction

The notions of "digitalization" and "artificial intelligence" are already firmly established not only in scientific but also in practical use. This has been facilitated by the rapid development of new types and means of communication, a huge increase in the flow of diverse information. If even with the emergence of steam locomotives, steamers and telegraphs the distances literally decreased and information began to spread incredibly fast, what can we say about the current state of the world when we reach other continents in a few hours, and you can contact people anywhere in the world almost instantly?

It is clear that all these achievements change our lives even on the level of everyday life, form whole new branches of economy, create new means of production, new relations between people, etc. At the same time, something goes into the past, changes, loses its former value, new economic and social problems appear. This once again proves that progress is very contradictory. Together with new achievements, it inevitably leads to socioeconomic and political contradictions.

These processes not only influence the development of scientific research in different fields, but also become objects of scientific analysis. Already in this regard, we can say that digitalization as a phenomenon can become the subject of, for example, philosophical, sociological, historical study. But how much does it penetrate into these sciences? How can it be defined in the methods and means of studying the different aspects of human society? To what extent is it right to mathematically test the most difficult subject to study—the human being as an individual, as a social being, and their social relations? How does historical science fit into the process of digitalization?

2 Methods

An important methodological question arises from the very beginning: what is digitalization? Do we not confuse it in our reflections with another term from our present life—"informatization"?

This is how the modern authors define these definitions. Under informatization they understand the application of means of computer engineering and corresponding software for acceleration of all processes of interaction (communications) between

people at the expense of transferred information. And by digitalization they understand a more complicated technological level. They explain that these are systems that allow replacing a person in the simplest areas of work, in order to work faster and more accurately, as well as to make optimal decisions in complex situations without involving a person. This means that we are actually talking about the transition to artificial intelligence technologies [1]. In other words, what can we talk about: new tools that help the researchers, or systems that replace them?

A contemporary monograph on Digital Humanities (DH) states that the present time is formulating new requirements for the human knowledge system. Access to research materials is expanding. Greater opportunities for communication and collaboration are opening up for scientists. They're adopting new research methods. Digital Humanities is an emerging interdisciplinary field of research that is interesting in its own right [2].

But, in our opinion, it is a question of understanding the process more from the point of view of informatization, rather than of replacing the humanities researcher with artificial intelligence. The authors of the monograph also link their methodological approach to the theory of information, which is now used in both natural and social sciences [2]. We see here a new area of interdisciplinary research, i.e. the study of the phenomenon of "Digital Humanities" itself, rather than the use of digitalization in research, the extent to which it affects the process and outcome of research.

3 Results

Mathematical methods are not used by historians for the first time. It is known from various studies that they were first used in the late XIX—early XX century, when the data of zemstvo statistics were analyzed. The modern author gives the names of pre-revolutionary historians who used the methods of mathematical statistics in their work on the sources. These are A. Kaufman, I. Luchitsky, N. Lubovich, N. Nordman. Present specialists in the application of mathematical methods in historical science also name G. Baskin, L. Kritsman, I. Rosnitsky as their predecessors, who paid attention to these issues in the 20s of the last century [3]. In the 30–40s, apparently, due to the shift of research interest in the field of socioeconomic history and the class approach to its analysis, these areas did not develop. Previous research methods were used in the study of sources. Elements of the statistical approach were most preserved in the study of archaeological and ethnographic material.

In the post-war years of the XX century there was a rapid development of electronic computers and cybernetics. As it was noted by us in one of the works, scientists of many specialties immediately appreciated the huge opportunities provided by not quite developed by modern standards of computer technology. Computers allowed processing large volumes of homogeneous information very quickly, making complex calculations, which previously had to be spent many months on. Thus, computing became one of the main tools in the hands of researchers. But it seemed

that in the field of humanities its application was almost never expected. However, even in historical studies, scientists had to deal with special types of sources—mass sources—which took a very long time to process. (See: [4]).

The source for the historian is the initial base material for scientific research. On the basis of its study and analysis, the research work is developed, scientific conclusions are drawn, the quality, scientific value and reliability of this work are identified. Historical sources are very different. They are mainly material evidence of the life of people in different epochs. Written sources, from individual words and inscriptions to large volumes of written documents, occupy an important place among them. They include various documents that reflect the development and complication of the state apparatus, its administration functions, etc., when the need for various types of documentation increases dramatically. Thus, homogeneous sources of mass character emerge. Prominent source historian B.G. Litvak noted that among the ancient documents there are few materials "that emerged outside the state apparatus in the broad sense of the word". But when sources of later periods are found, "closer to our time", they become more homogeneous, "wider in scope and clearer in form" [5]. Thus, in order to obtain the data necessary for historical research, it is necessary to process significant arrays of similar documents, which tend to be standardized [5]. These circumstances, including the routine type of the process of working with the source data, led scientists to the idea of applying electronic data technology to their processing and analysis. By the 1960s, there was already some experience that made it possible to "formulate methodological recommendations" for docking "traditional source studies using new mathematical methods" [5].

The available theoretical basis made it possible to apply the computer capabilities to accelerate the work on mass sources. Pioneers in this field were employees of the Department of Source History of the USSR, Faculty of History of Lomonosov Moscow State University, headed by Professor I.D. Kovalchenko. It was he who suggested applying mathematical methods and computers in historical research, creating a team of source specialists, programmers and operators who worked on the computer. Later, this group was transformed into a laboratory (See, for example: [6], [7]).

The author of the study on the life and research activities of academician I.D. Kovalchenko notes that the creation of this new direction was that "source study of mass sources has become a complex scientific topic of the Department of Source Studies of the Faculty of History of Moscow State University. This was done in the 80's by the widespread presence of large complex programs, projects in the work of scientific teams, and in the 60's this was unusual, especially in the field of humanitarian research" [8].

One of the first results of research and practical work on the application of mathematical methods and computers in historical science were the new training courses and manuals developed by I.D. Kovalchenko and his colleagues for future source historians. At the same time, research began to appear, in the preparation of which new instrumental methods using computers were applied.

In 1974, the USSR Academy of Sciences Publishing House "Nauka" published a monograph by I.D. Kovalchenko and L.V. Milov "All-Russian Agrarian Market of

XVIII—early XX centuries: experience of quantitative analysis". The abstract stated that it "represented the experience of applying methods of mathematical statistics and modern computer technology in historical research" [9].

In the monograph "Mass Sources on the Socioeconomic History of Russia in the Period of Capitalism" (M. 1979) I.D. Kovalchenko notes that, despite the obvious results, the sources of mass sources are still in the process of formation and development, and many general and specific problems are still waiting for their solution (p. 5). The monograph "Mass Sources on the Socioeconomic History of Soviet Society" (M., 1979) indicates the masses of sources that have been processed on computers, some of which are introduced into scientific circulation for the first time. We are talking about population censuses, current account data, annual reports and other sources. The technique of using such sources is summarized and new methods of their study are developed, in particular, with the use of computers and mathematical methods. Thus, the authors have shown the effectiveness of the applied quantitative methods, which allowed to give the results needed for scientific conclusions in a short time.

The achievements of I.D. Kovalchenko's scientific activity gave rise to a response from the domestic and world historical community. National and international seminars, conferences, etc. on this new and very promising topic were held. The Commission on the application of mathematical methods and computers in historical research headed by I.D. Kovalchenko was established at the Department of History of the Academy of Sciences of the Soviet Union in 1968. This fact confirms the recognition of a new promising scientific direction in the study of historical sources and the priority of the Kovalchenko school in this area.

At the same time the works of the employees of the Department of Source Studies of the Faculty of History of Moscow State University appeared, where specific scientific conclusions were given, supported by the data obtained as a result of processing large arrays of sources on computers. Those were the works of I.D. Kovalchenko, L.V. Milov, V.Z. Drobizhev and A.K. Sokolov, etc., where various types of mass sources were processed on the computer, such as trade union census data and other sources suitable for algorithmization. Mathematical methods were successfully used by the medievalist K.V. Khvostova, who applied them in the analysis of medieval socioeconomic history. G.A. Fyodorov-Davydov, Professor of the Department of Archaeology of Moscow State University, applied them in archaeological research, etc.

In 1979, I.D. Kovalchenko, Corresponding Member of the USSR Academy of Sciences, organized and headed the All-Union seminar "Quantitative methods in historical research". At the Institute of History of the USSR Academy of Sciences a laboratory for the application of mathematical methods in historical science was created. There were names for a new direction in the study of historical science—"cliometrics" or "quantitative history". They began to appear in works on application of mathematical methods in history.

Serious changes in this area took place in the process of world technological breakthroughs in electronic engineering, programming and communications. Personal computers, scanners, printers, tablets, smartphones, compact information keepers,

etc. appeared. They all fundamentally changed the work of a scientist. They, together with new communication and information search systems, together with e-mail and other new means of communication massively came into use. Many previous rather time-consuming operations became simpler and easier: from typing text, editing it, saving it, sending it, etc., to working with the sources themselves (See, for example: [10]). We noted that many handwritten and printed documents have now gone through the digitization process. This makes it easier to work with them, makes them more accessible, because one can use them literally without leaving home, without visiting libraries, archives and other repositories of written and printed sources. At the same time, digitization preserves the originals, because over time, the material on which they are written or printed (mostly paper, of course) becomes older and vulnerable to exposure [4].

All these changes were rethought and mastered by I.D. Kovalchenko (who in 1987 was elected an academician of the USSR Academy of Sciences) and his associates and followers. The Laboratory for the Study of Quantitative Methods Application in Historical Science was transformed into the Department of Historical Informatics in 2004, which was headed by I.D. Kovalchenko's pupil, at present—L.I. Borodkin, Corresponding Member of RAS. Its team successfully develops and expands the sphere of application of computer technologies for studying history. As it can be seen from the very name of the department, still here we are talking about the informatization of historical science.

In higher education institutions with historical faculties, students study subjects that introduce future historians to the world of modern digital technology, computer science and communications. In the Russian Federation there is an association "History and Computer". It issues its newsletters and holds annual conferences.

Now historians face much wider tasks than computer processing of this or that type of sources (See: [11]). At a minimum, judging by the issues discussed by the scientific community, we are talking about the following problems: history in cyberspace; history of computer developments in historical science or historiography of mathematical and other computer methods of study of history; digital technology in the service of historians; digitalization of historical science and historical education; creation of computer databases on various sections and periods of history; digitization of historical sources; online presentations of historical material; electronic historical publications, online conferences and webinars, etc.; electronic resources in historical research; historical portals and websites, etc. (See, for example: [12]).

L.I. Borodkin together with V.N. Vladimirov have analyzed the latest international discussions on the problems of digitalization in the field of historical science. They note that a serious topic is the problem of new digital data appearance, tools for their research and ensuring their availability. Now the work on mass digitization of various documents, books, historical sources, etc., both at the state and departmental levels, as well as at the private level, including at the expense of so-called "activists" who put digitized arrays of data in the Internet is in full swing. These same data are generated in huge quantities by various economic, political, social structures, institutions, etc. [13].

Another important issue, in their view, is the creation of new software to work with various types of digitized information and sources. Equally serious remains the problem of connecting "two cultures", i.e. harmonizing the roles of historian-researcher and electronic and programming specialists. In our opinion, a historian rarely happens to be capable of working at the level of a qualified programmer. Similarly, a technician or a mathematician is hardly ever capable of mastering the profession of a historian at a high level. The seeming "simplicity" of studying history, considering it as a kind of fiction, superficial acquaintance with facts and events does not mean the formation of abilities to analyze and interpret the obtained material, to understand the historical process in its regularities and nuances, to create a complete historical research. We know this from a number of amateurish attempts of new interpretations and periodizations of world and national history by individual mathematicians, which have not led to anything fruitful.

Some authors note that mathematical methods can be applied quite restrictively. And this depends primarily on the nature of the source being studied. Medieval historian K.V. Khvostova points out in her research that no mathematics (let us add—no modern digitalization and informatization) will replace qualitative creative analysis, qualitative explanation of causes and consequences of phenomena, and their origin. Quantum methods should first and foremost serve as a supporting tool that facilitates and simplifies the processing and analysis of only *a certain type of sources.*

Speaking about results of application of mathematical methods, the modern author notes that "it is not a question of acquisition of mathematical accuracy by history, but expansion of methodical arsenal of the historian, as well as the possibility of reception of new data at more perfect quantitative and qualitative level. Historical science does not lose its specificity, because mathematical techniques do not replace qualitative analysis and do not affect the subject of historical science. So far no mathematical methods have been developed that are not related to the qualitative side of the work. There are no universal methods of research for all historical problems, for all historical sources. Initial theoretical and methodological principles of historical science determine the goals, ways and methods of research. On their basis there is a selection, analysis and generalization of the factual material" [3].

L.I. Borodkin and V.N. Vladimirov note the increased availability of digitized sources and other historical materials, which can be found in various databases. They write about the emergence of a number of "new research tools that allow for more efficient (though often auxiliary) processing of these sources". But it is immediately pointed out that it takes time to understand and evaluate the effectiveness of all this. Actual results "can be obtained in specific historical studies that are based on digitized sources and using appropriate methods and technologies for their analysis. They should provide an increase in historical knowledge" [13].

Thus, based on the opinion of the most authoritative modern domestic specialists in the field of historical informatics, we can conclude that digitalization in historical science plays the role of an auxiliary tool and, in general, it serves here exactly as informatization.

The modern researcher really has a rather wide range of mathematical and statistical techniques. The scientist's workplace itself has changed, which allows to use the entire range of digital technologies. We cannot help but notice, for example, the serious role of computer technologies in decrypting historical texts written in lost languages or by means of secret writing. Earlier specialists also used mathematical methods when trying to read such documents, but manually, using long calculations and layouts. They had to have deep linguistic and historical knowledge as well as enormous patience. And there are very few such unique specialists. Computer programs make it easier and faster to solve such problems. With their help it is possible to attribute monuments of writing, to establish authorship, to establish the original among numerous lists, to define a place and time of creation of the text. You can recreate the source, predict the content of lost fragments, and clear the original text from late layering. But there are still many methodological and procedural problems associated with the study of sources that remain unresolved (See: [3]). In the asset of modern archaeology, for example, computer virtual models are used which help to recreate the appearance of found artefacts even in extremely scarce fragments. The received data can be immediately processed or transferred to research centers. And by means of 3D-printers it is possible to receive their three-dimensional model. So, a completely new space of research technology is actually formed before our eyes—historical 3D-reconstruction [2]. With the help of such programs and automatic drones, which scan the surface of the earth in the area of excavation, it is possible to reconstruct both individual buildings and entire settlements, as well as ancient communication routes, necropolises, places of battle, etc. These technologies can be used for scientific research, as well as for museum and educational purposes.

4 Conclusions

Our critical analysis of the historical literature on this issue shows in a historical perspective how mathematical methods, methods of informatization and digitalization were gradually incorporated into the use of one of the most human sciences—history. It is impossible not to note a huge contribution to this science by the outstanding Russian historian and source researcher, academician I.D. Kovalchenko, his associates and followers, who paved the first ways for the introduction of mathematical methods and computer technology in historical research.

Summarizing the views of most modern specialists in the field of application of informatization and digitalization in historical research, we believe that it is impossible to completely replace man in historical, and other humanities sciences. The craft of a historian is akin to art. When working with historical sources there are a lot of associations, feelings, doubts, findings and insights that are unlikely ever to be under the power of artificial intelligence. The researcher's life experience plays a great role in this process. Digitalization significantly simplifies the technical side of historical research, makes the work of a historian more intensive and productive, opens up new vast information and communication opportunities. The problems of

interaction between humanities and natural sciences, digitalization is a vivid example of interdisciplinarity, which leads to a new quality of human science research. But with regard to the science of history, we have the right to talk not about digitalization as such, i.e. at least a partial replacement of the researcher by artificial intelligence, but about the broad informatization of historical research, improving the work of the historian. Thus, historical science is not yet threatened by the risks assumed by some experts in connection with the development of the digital economy: the disappearance of some professions, the replacement of man by artificial intelligence, an unprecedented increase in unemployment related to this, and so on.

From the point of view of analysis of previous experience of human history, we can assume that mankind will cope with these risks. After all, there was a time when, during the industrial revolution at the end of the XIX century when mechanisms and steam engines appeared, masses of people were out of their usual work, which gave rise to the movement of Luddites, who were smashing machines, which they thought were taking away means of their livelihood. But relatively little time has passed for people to realize that it is not the machines that have impoverished them, but a new social relationship between an employee and an employer. And the development of the already mechanized industry soon still required new workers. And nowadays, with all the mechanization and automation, it is still too early to talk about extreme unemployment. Some professions are disappearing, new ones will appear. The question is different, and we are among the first to pay attention to this problem. Humanity has entered a time of actively developing contradiction between new high-tech digital means of production and the production and social relations lagging behind technological progress, with the resulting socioeconomic and political consequences. Risks do not arise only in the economy. A massive and uncontrolled digitalization can lead, paradoxically, to a cultural crisis. Modern man is losing the general cultural skills. It has turned out that it is much easier to master the skills of using the most modern gadgets than to learn to read and write by hand. The Internet provides not only useful information. We are no longer talking about electronic fraudsters, cyber robbers, cyberwar, etc. How ready is humanity for this? It all depends on who is in whose hands, how and in whose interests all the super achievements of the digital age, which we are literally busting into, will be used.

Assessing the Capacity of Structural Segments of the Artificial Intelligence Market

Boris E. Tokarev, Tatyana A. Beregovskaya, and Roman P. Tokarev

Abstract The paper provides a situational analysis of the state of artificial intelligence technologies in the world. The aim of the work is to obtain high-quality assessments of the state of development and implementation of artificial intelligence technologies in various areas of life. The capacity indices of three structural segments of the artificial intelligence field (scientific publications, patenting and startups) in the world and Russia have been estimated. The article presents quantitative indicators characterizing the capacity of the structural segments of artificial intelligence developments. The current situation of publishing scientific activity in Scopus and Web of Science and also in comparison with the Russian database of scientific publications indexing is analyzed. The leading countries for publications in indexed databases are identified and their strengths and weaknesses are analyzed. Leading organizations and companies engaged in scientific activities in this area have been identified and evaluated. A comparative analysis of the trend of developments patenting using artificial intelligence has been provided. Leading countries and companies actively patenting their developments have been revealed. The paper analyzes the features of patenting and ownership of patent portfolios. The results of the analysis of patent portfolios owned by global companies are shown. The influence of the size of the patent portfolio on the market positions of world developers of artificial intelligence technologies is determined. The current situation with venture investment in the development of artificial intelligence technologies is described. The leading role of machine learning at the present stage of development is shown. Summarized statistics of startups using these technologies are given. The position of Russian scientists and developers regarding the leading positions in the segments of scientific publications, the development of new technologies and the introduction of

innovations in practice is shown. The study showed which of the areas at the current time are actively developing in the most developed countries from a technological and computer point of view. The forecasts of the development of this technological direction for implementation into practice are analyzed.

Keywords Artificial intelligence · Market capacity · Patent · Startup

JEL Classification O32

1 Introduction

The purpose of the paper is to make an attempt to assess the experts' expectations concerning the prospects of the application of Artificial Intelligence (AI) technologies.

The authors set the task to explore the trends in the segments of scientific publications, ownership, and use of patents for inventions, as well as the dynamic pattern of venture investments of AI startups in the world and Russia. The study is aimed to search for quantitative indices evaluating the capacity of the segments.

The scientific novelty of the work lies in the fact that when analyzing the state of the market, the state of the interconnected and interdependent structural elements of the scientific and technological direction was studied. The predetermination of scientific developments that positively affect the acquisition of new technologies and the obtaining of patents for them and the development of a venture business that assumes the risks of investing in high-risk projects is shown.

Artificial intelligence is a combination of multiple technologies that allow machines to recommend or even make independent actions, as well as self-learn or to help a man in his activities. Most experts and specialists cannot reach a common opinion on AI definition.

The tasks facing them require to make decisions within the allocated powers, or to help a person in his activities, reducing costs, risks, consumption of efforts, but as a result increasing the efficiency of production.

The rapidly developing technology complicates the identification of an exhaustive list of AI applications. It is being actively introduced in many fields around the world, shaping our future on a global scale in many sectors of the economy [35].

The subject-matter of our research is three important structural segments of the AI market, directly related to the algorithms and technologies of their application. We have an interest in the issues related to publication activity on AI topics, AI patenting of developments, as well as the state of venture investment in AI startups. We analyzed the dynamics of scientific publications on AI topics, patenting developments with using these technologies and also the state of venture investment in AI startups. The purpose of the article is to assess the capacity of each segment and its prospects.

2 Background and Methodology

Most of the advanced countries in the field of information technology are actively engaged in a study of the AI state. For example, British patent office data [15]; the AI patent research has been conducted by the European Patent Office's (EPO) PATSTAT in 2018 [29]; annual report of Stanford University [40].

Leading international consulting and expert agencies pay close attention to the AI field. Among them are KPMG [19], McKinsey (McKinsey 2019), PWC [33], Accenture [35], Deloitte and Touche [8] and others authors, whose task is to find the direction of effective development of the world and national economies.

3 Discussion and Findings

3.1 The Impact of AI on the Potential of Economic Growth

From an analysis of global sources of information, it follows that the trend for advanced research and development (R&D) in the area of AI has clearly become apparent. The investment in the full range of such technologies is $150 billion [8].

The Global AI market in 2018 amounted to $21.5 billion, and by 2024 it is projected to be $137.5 billion [18]. International Data Corporation plans a 50% increase in global AI adoption by 2023. Russia also expects a 6.5-fold growth in the global AI market over a five-year period.

Accenture study [1] conducted in 12 developed economies shows that AI can double the annual rate of economic growth in 2035 by changing the nature of labor and establishing new relations between man and machine. The impact of AI technology on business is projected to raise labor productivity up to 40% and allow people to efficiently manage their time.

Russia is also intensively developing AI in the framework of an integrated digitalization program. However, Russia started developments later than some other countries, therefore it falls behind by time and scope of works performed. The Ministry of Digital Development, Telecommunications and Mass Media of the Russian Federation reported that in 2018 the volume of domestic AI market amounted to 2.1 billion rubles. Based on the results of the end of 2019, a preliminary assessment of the AI market in the Russian Federation is given in the amount of 8.4 billion rubles, which characterizes a significant four-fold increase in monetary terms.

But with this growth, ordinary consumers see a significant penetration of artificial intelligence technologies into daily life, primarily in electronic communications, banking, process control, and production robotization.

The use of AI in the world in the formation of morbidity control during the pandemic of the caronovirus is very indicative.

The forecast for the artificial intelligence market in the Russian Federation is 160 billion rubles by 2024. A tremendous increase of 20 times along with joyful anticipation still raises more questions. Experts hope the annular growth of investments in the development and implementation of AI technologies in the Russian Federation will be 30% [14].

Estimates of PricewaterhauseCooper [33] show that the greatest contribution of AI into GDP is now observed in China (about 26%) while in other regions of the world developed from a technological point of view this figure is 11.5% on average. The contribution of the rest of the world, including Russia, to GDP is slightly more than 5%.

3.2 Comparative Assessment of Publication Activity Around the World

By mid-2019, over 1.6 million scientific papers related to AI were published in the world. According to the analysis of the World Intellectual Property Organization WIPO, the annual growth of over 5% of scientific publications on topics related in one way or another to AI supports the keen interest of all participants [57]. From 2011 to 2018, about 600 thousand articles dedicated to AI were published. In Russia, there were only 1300 in 2018 in comparison with the United States—over 18 thousand for the same year [37].

The AI Index determined that the leaders in the area of scientific work are the European Union, China and the USA [2]. The same resource showed that the development and publications of state organizations prevail in China, while private ones dominate in the USA. EU countries occupy the positions of followers in both directions of development. Russia isn't on the list, which means a strong backlog according to this criterion.

The Association for the Advancement of Artificial Intelligence [47] announced at a conference in 2018 its data on quantitative indices of submitted and accepted papers among the countries. By a significant margin, China and the United States lead (in general 70% of the suggested materials belong to them). At the same time, the number of suggested publications in China is approximately 1.3 times higher than in the USA, however, both countries published an equal number of papers.

Scientific conferences show the interest of researchers and practitioners in the AI topic. This interest is explained by a 2-7-fold number of participants in the largest world conferences over 2012–2018. Moreover, the absolute number of participants is up to 8 thousand people from different countries of the world [2]. The number of participants in small and local conferences is also growing multiply.

The leader among the European countries with a significant margin is Germany [10]. According to this review, Russia follows the UK in the rating.

The study of the Higher School of Economics [13] found out that the positions of Russian authors have changed little over 2007–2017 (13–14 places among the

countries of the world). Amazing stagnation. Moreover, the situation is the same both for publications indexed in Scopus databases and Web of Science. During 2019, there was a trend towards the growth of Russian publications in international periodicals, but their citation index remains low.

The resource (Skolkovo database of artificial intelligence applications) monitors publication activity on AI in Russia. The results show the leaders are academic institutions and technical and technological universities of the country. The largest proportion of publications in Q1 belongs to Skoltech.

The overall quantitative indicators are pretty small. For example, in 2019 ITMO with 200 publications was a leader given that RAS and Moscow State University published slightly more than 130 articles.

3.3 Analysis of the Dynamic Pattern of AI Developments Patenting

It is obvious that in scientific-technical and technological developments there is an apparent correlation between conducted studies and submitted applications for patent documents.

In the work [51], the authors analyzed the state of patenting in the area of AI based on data from the World Intellectual Property Organization WIPO [57]. The work showed in which countries and which companies occupy leading positions in such technologies. It was concluded that the prevalence of ML-technologies, the share of which is approximately 60% of all AI direction.

A review of Tractica company revealed that, as of the end of 2018, AI technologies have been applied in 258 areas of life [52]. Tractica has distinguished 27 promising AI market segments.

As of the end of 2019, the total number of core AI algorithms include 19 areas and 30 functional applications.

Such a large number of areas and applications pose challenges to up-to-date and impartial statistical analysis of patent activity. All available sources of patent information are much delayed in terms of time to submitted applications for inventions. The problem is complicating because it is not always possible to make an expert assessment of AI invention applications and classify them since the technologies are fast-developing.

In practice, many applicants indicate several subject areas for patenting and, in addition, simultaneously in several countries, as a rule, the most advanced in this technological direction. Among such countries are the USA, Japan, South Korea, China, the European Union. Domestic developers also follow these paths, but they have financial restrictions on paying for the examination of applications and fees for maintaining patents.

There are only 13 companies in Russia, which conducted active research in the area of AI. However, according to studies of Russian banks as leaders in technology

implementation, from 2017 to the present, the number of such companies has grown by almost 4 times. In particular, the Sberbank forecast indicates that by 2030 the number of companies involved in the development and implementation of artificial intelligence technologies can reach one thousand [27].

The WIPO Global Report [57] evidenced that the leading positions in AI patenting are held by global corporations engaged in high technology, information technology, automotive engineering, and banking. The largest portfolios of AI patents are owned by IBM and Microsoft. The top 20 companies account for more than half of all existing patents.

A significant increase in patent applications occurred after 2014 in the widest areas of application, which was evidenced by a study conducted in the UK [15]. In the work [51], the authors showed a trend towards an increase in the share of ML in the total number of AI patents, which reached 60% and has an ongoing upward trend.

Under WIPO estimates [57], Russia ranks 16th in the world by the number of applications for AI inventions. Along with the positive domestic trend of AI patenting, the indicators of applications for international patents [13] seem low.

The share of applications of domestic applicants to the Russian Patent Office (Rospatent) is a little more than 60%, while the rest is provided by foreign companies, which actively occupy the technological space in the country's economy. But these modest indicators aren't comparable with the activity of patenting in the leading country, in China, where about 6 times more applications are submitted for inventions. And this trend is growing, and patenting in the Russian Federation for several years has been at approximately the same level.

Detailed information about Russian companies that already use AI can be found on the "Map of Artificial Intelligence of Russia" [16]. It follows that AI has found the greatest use in business analytics (54 companies use it), computer vision in drones and drones (48 companies), in healthcare (40), speech processing systems (40) [11].

Based on own data, the Infosystem Jet analytic company has shown that Russia has tripled the introduction of AI projects over 2017–2019.

3.4 Venture Investments in AI Startups

An important factor of AI prospects analysis is the practical application of achievements in specific solutions. New implementations can be traced in AI startups. An index of the venture investor's interest and attitude to AI is the number of startups. The investments in such projects are growing sustainably throughout the world. Analysts from Frost and Sullivan project investments in AI startups at 30% annually on average across the world.

McKinsey simulated AI technology development [24] and the models showed that by 2030, up to 70% of companies in the world will be able to use at least one of the AI technologies. About half of the companies will use five technologies.

The Economist magazine surveyed over 400 top managers of private and state-owned companies in the world [46]. The findings showed that the majority of respondents recognize the introduction of as very promising. Quantitative indicators display that 27 companies have implemented AI, and 46% are working on pilot projects.

But not everything is so rosy so far. 40% of European AI development companies don't use it themselves. This conclusion was made by the specialists of the venture company MMC Ventures based on a survey of 2800 startups in 13 EU countries and published in 2019 [26].

As declared by Adobe, venture investments in AI startups have grown sixfold over 2000–2017. Global investments in AI startups have an upward trend from quarter to quarter, but this growth is unstable. For example, the growth of the first quarter of 2019 against 2015 is fivefold, and in the second quarters, the figure was 7.4 times [44]. The number of AI startups from January 1995 to January 2018 increased from zero to 800 per year [40].

An eloquent evidence of investor interest in the topic of artificial intelligence is the volume and quantity of investments, especially venture capital, since there are high risks of non-return on investment in development. Russia lags very markedly in these indicators, which is understandable, if we take into account the above quantitative indicators of scientific and patent activity, and their share in the world (Fig. 1). And the leading ones are countries, which conduct numerous developments and patent the solutions obtained, actively publish and interact with organizations around the world.

The trend of venture investments in AI of Russia is positive, however, the amount of finance in comparison with the world is insufficient. But the proportion of these investments in AI prevails over all other areas both in the world and in Russia. It

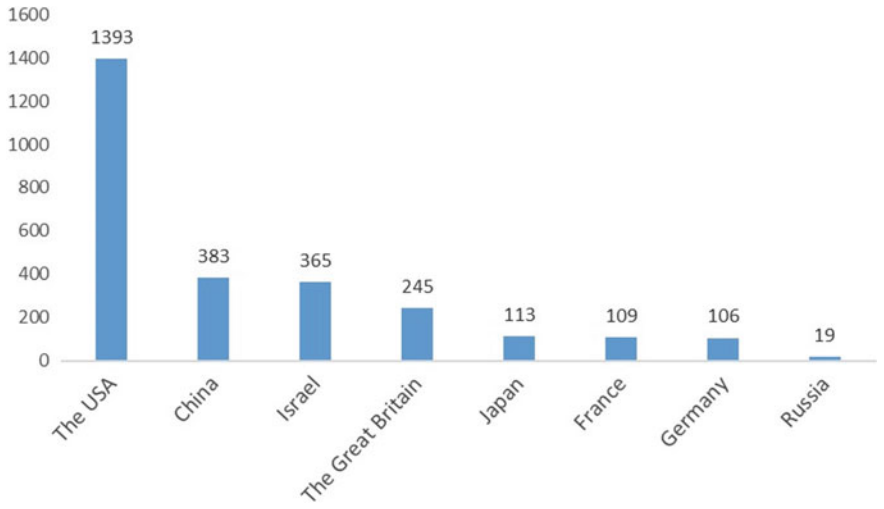

Fig. 1 Implementation of startups in the field of AI by country (made by the authors according to WIPO)

is indicative that we are several years slow. In particular, the number of AI venture transactions in China is declining in 2019 (reaching 131 over the first six months), while 496—in 2018 [6].

However, investors still have some suspense. This is detrimental to the attitude of the venture capital market to the application of AI technologies. Since 2017, the Russian venture investment market has suffered a decline. After a period of optimism, investors change high expectations with waiting strategies. Nevertheless, there is also an optimistic situation in the market.

Domestic companies are taking measures to keep up with world trends in this area. They see the multiple benefits of introducing artificial intelligence, despite the possible risks. Each third company in the financial, oil, gas and public sectors reported on the successful implementation of artificial intelligence.

4 Conclusions

Developing new technologies and investing in them, publishing findings and recognizing by the scientific community, protecting intellectual property, getting developments into use, venture investments in high-risk projects are links of a single chain of innovative activity. The outcome of AI implementation is contingent on the state of each link. When investigating new technological lines of development, it is important to assess the state of the above links. The mentioned structural segments, publications, patenting and implementation of innovations in startups describe the movement of the process. In the paper, we managed to assess the capacity of a new forward-looking sector of the economy that is just emerging. A situational analysis gives reason to predict a quite explosive growth of venture and institutional investments in AI and new products and services designed for individuals, business and government.

Cross-Cutting Digital Technologies in the Management of the Competitiveness of High Technology Products

Nataliya G. Shalamova, Lidia S. Zelentsova, and Yulia V. Vorontsova

Abstract The article is devoted to the search for advanced tools for creating a fundamentally new level of management system for the competitiveness of high-tech products in the conditions of using end-to-end digital technologies. The necessity and ability of effective integration of functions and tasks of competitiveness management into the intellectual system of the enterprise for the purpose of proactive provision of analytical and forecast management data are proved. The purpose of the study was to develop an approach to identifying predictors that provide reliable analysis and forecasting of the competitiveness and competitive price of high-tech products, integrating into intelligent predictive Analytics models. The object of the study was the enterprises that produce flight equipment, which are most characterized by science intensity and innovation. The subject is the process of integrating "figures" into the management of competitiveness of high-tech products. The novelty consists in the development of: an original method for selecting key competitive indicators according to the proposed criteria for the formation of a complex of predictors; a universal model for quantitative assessment of competitiveness based on the formation and analysis of various scenarios, which allows you to predict the indicators of competitiveness in dynamics, and determine the characteristics of products for a given competitiveness. The practical significance is that the problem of advanced assessment of competitiveness, based on the implementation of the search forecasting methodology, and the problem of forming a given competitiveness based on the methodology of normative-target forecasting through scenario modeling have been solved. The results of the developed model of quantitative assessment of the competitiveness of high-tech products based on the formation and analysis of various

1 Introduction

The digital transformation that permeates almost every aspect of people's lives has primarily touched the high-tech sphere. Knowledge-intensive and high-tech enterprises faced the problem of searching for new tools for the management of the competitiveness with due account for characteristics and features of the business ecosystem [13]. The peculiarity of such enterprises, in particular, is the high cost of error due to the underestimation of the significance of the pre-project and project stages. Competitive advantages are determined as early as at the preliminary design stage and are shaped and formalized within the framework of pilot and batch production and postproduction interaction with the consumer. Knowledge-intensive enterprises must be able to create the necessary conditions in the internal environment for the development of the innovative capacity in advance, which ensures high level of competitiveness [15].

In order to enter the market with a definitely competitive product that would be protected against random factors as much as possible, the system of management of the competitiveness of high-tech products (MCHTP) must be proactively provided with analytical and forecasting information about domestic and international product requirements; sales markets; design, production and sales technologies; consumer quality requirements; the state of business in the internal environment and the state of business of competitors. Of course, the efficient implementation of processes of MCHTP is involved with the consideration of large numbers of factors that are inherently diverse and scarcely ever measurable, which renders making reliable and efficient management decisions difficult [7].

Under the circumstances, the integration of digital technologies in the processes of MCHTP becomes an efficient creative and routine tandem, which creates new opportunities for the transfer of a variety of functions of management of the competitiveness to intelligent systems based on high-performance information and communication technologies (in particular, predictive analysis), interaction networks, cloud technologies and high-speed networks [12]. This research is aimed at elaborating the methodological aspects of the assessment of the competitiveness of high-tech products as an indicator for making management decisions and identifying the most significant indicators for the formation of a set of predictors of predictive analysis.

2 Background and Methodology

At the moment, there is a need to improve the efficiency, reliability and feasibility of organizational and management decisions for the use and development of the potential of knowledge-intensive enterprises, which is made possible through the use of cross-cutting technologies, in particular, predictive analysis methods.

As noted in [4], digital analytical systems working with big data contain intelligent real-time models. For example, within the framework of predictive analysis, the consolidated algorithm of which with advanced analytics is shown in Fig. 1.

The market is oversaturated with a variety of software and tools of predictive analysis for processing of both structured and unstructured data, learning, putting forward and assessing hypotheses. This system consists of four levels:

- integration in hybrid networks (a kind of artificial intelligence systems);
- high-speed data processing tools;
- specialized access to data;
- patterns related to analysis, modeling, forecasting, scenario simulation, machine learning, predictive analysis, optimization modeling, and planning.

Predictive analysis is of special significance for knowledge-intensive organizations in terms of development of competitive commercially successful products.

It should be noted that the implementation of the concept of digitalization of industry entitled "Industry 4.0" in Russia is of prime interest for the improvement of knowledge-intensive and high-tech industries with a view to increasing their competitiveness in the world market [9, 11].

Russian knowledge-intensive industry is characterized by a step-by-step movement towards the "intelligent" production, which provides for the implementation of information and communication technologies and cyberphysical systems at all life cycle stages of a product [8, 14]. Against this background, opportunities are created for the transition to the forward-looking MCHTP on a brand-new level.

The completed research is indicative of high rates of the expected GDP growth due to the implementation of digital technologies over the next 5 years both abroad and in our country. Thus, in Russia, the effect of the use of Artificial Intelligence and robots in production may become as high as 34% of the total GDP growth by 2025 [1].

3 Discussion and Results

Digital technologies in the management of the competitiveness of high-tech products make it possible to improve its efficiency. However, the potential of digital technologies can be implemented in case of the transformation of the system of MCHTP in the following areas:

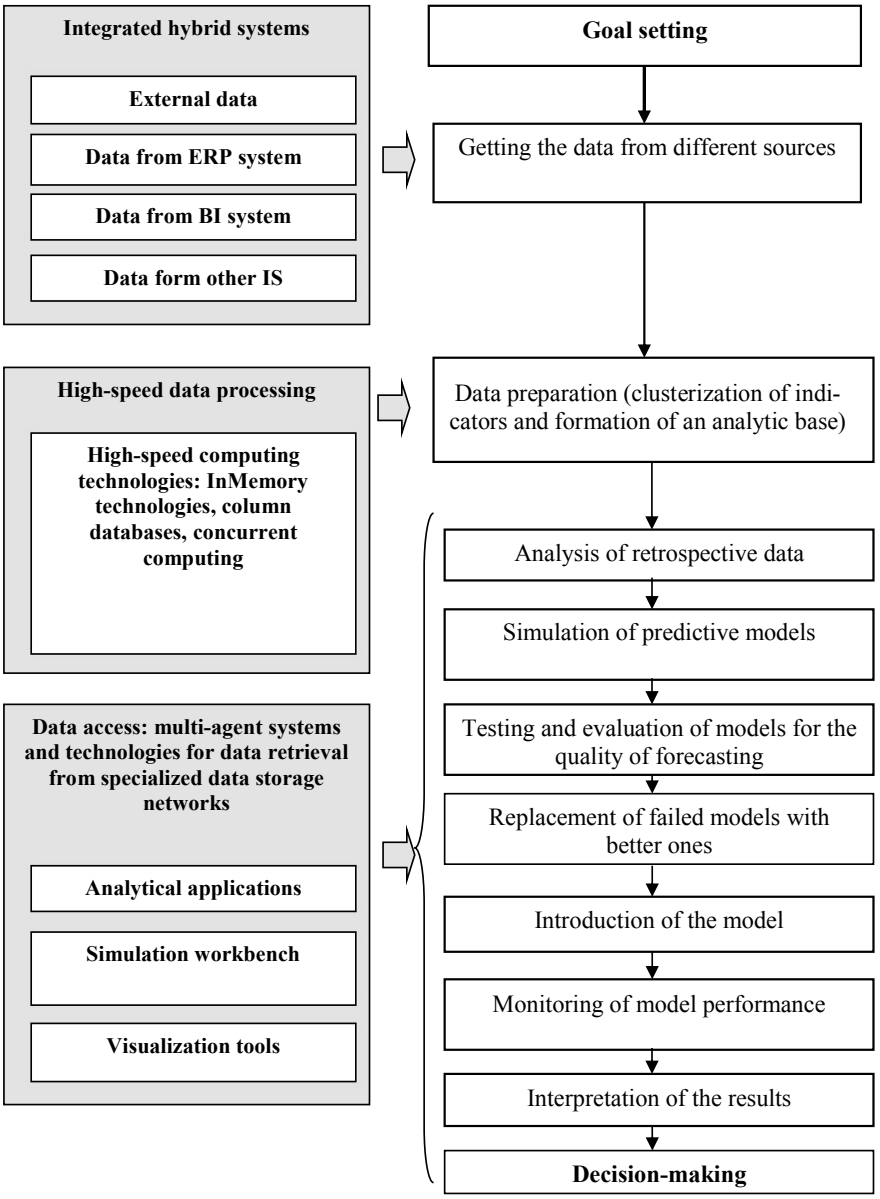

Fig. 1 Consolidated algorithm of predictive analysis in the context of the use of cross-cutting digital technologies

- seamless incorporation of the management of the competitiveness into a unified system of management of a knowledge-intensive enterprise as a subsystem;
- change in the status of the system of MCHTP as an intelligent decision-making system;
- monitoring and development of new methods and models of MCHTP with reference to the life cycle stages [5].

The guidance papers must meet various requirements determined by the specificity of the competitiveness of high-tech products as a subject to management [10]. We can cite the following basic requirements:

- the use of a multitier structure of indices of competitiveness;
- consideration of the multidirectional influence of factors that determine the competitiveness;
- consideration of various decision options ensuring the targeted level of competitiveness;
- reflection of changes in the level of competitiveness over time;
- consideration of a high level of uncertainty at the pre-project and project life cycle stages due to the lack of exhaustive and correct information on the trends of scientific-and-technological advance, change in the preferences of customers, innovation policy of competitors, etc.

Under the Data Mining concept, the most important tasks of MCHTP system are the preparation of initial data and simulation of a predictive model for quantitative assessment of the competitiveness of high-tech products, its verification and application for the projection of changes/dynamic pattern of competitiveness with regard to external and internal factors and making efficient management decisions in this area.

The preparation of initial data for a quantitative assessment of the competitiveness of the type of high-tech products under consideration means the collection and analysis of statistical data on high-tech products in the world and domestic markets, including information on technological development trends, consumer requirements, in characteristics of similar competitors' products, etc.

Based on the collected information, we can identify a range of predictors, technological and economic features that form the competitiveness of high-tech products in the global (domestic) market and define values for the products of the company and its competitors.

For the predictors that enable reliable analysis and prediction of the competitiveness and competitive price of high-tech products to be identified, we have used a dynamic assessment method. This method is an iterative selection of features by specially designated criteria.

It is suggested that the following criterial function should be used for the selection of predictors at the n-th iteration:

$$\Pi_{\mathrm{n}}^{o}(t) = \max_{p \in Q_n(t)} \sum_{\lambda=1}^{k} \Pi_{\mathrm{p}\lambda}(t) x_{\mathrm{p}\lambda}(t), \tag{1}$$

where

$П^o_n(t)$ is the value of criterial function at the n-th iteration at the point of time t;
$П_{p\lambda}(t)$ is the value of the p-th predictor in terms of criterion λ at the point of time t;
$p\left(p = \overline{1, P}\right)$ is the predictor;
$\lambda\left(\lambda = \overline{1, k}\right)$ is the criterion for the selection of predictors;
$t\left(t = \overline{1, T}\right)$ is the point of time;
$n(n = \overline{1, N})$ is the number of iteration;
$Q_n(t)$ is the set of predictors that were taken into consideration for the selection of predictors at the n-th iteration at the point of time t, $Q_{n+1}(t) = Q_n(t) \backslash p^o_n(t)$;
$p^o_n(t)$ is the predictor that was selected at the n-th iteration at the point of time t using the formula (1);

$x_{p\lambda}(t)$ is the Boolean variable

$$x_{p\lambda}(t) = \begin{cases} 1, \text{if } p - \text{th predictor corresponds to criterion } \lambda \text{ in peroid t;} \\ 0 - \text{in the opposite case,} \end{cases} \tag{2}$$

Iterations for the selection of predictors at the point of time t continue if the following condition is fulfilled:

$$П^o{}_n(t) \geq \Pi^{крит}(t) \tag{3}$$

where $\Pi^{крит}(t)$ is the specified minimum value for the selection of predictors at the point of time t.

The final check of results obtained is performed according to the impact:

$$F_p(t) = \sum_{\lambda=1}^{k} \alpha_{p\lambda} B_{p\lambda}(t) \geq \bar{F}(t), \tag{4}$$

where

$F_p(t)$ is the impact of p-th predictor on the competitiveness of high-tech products at the point of time t;
$\alpha_{p\lambda}$ is the weight coefficient of the p-th predictor in terms of criterion λ;
$B_{p\lambda}(t)$ is the numerical score of the influence of the p-th predictor in terms of criterion λ for the phenomenon under consideration in case of a change in its value by $\pm 10\%$ (this value is usually used for the assessment of sensitivity) at the point of time t;
$\bar{F}(t)$ is the mean value of the impact at the point of time t.

Criteria for the selection of predictors: high sensitivity to external and internal changes; the ratio of technological state of the art to the price; degree of innovation, degree of risk, etc.

During the preparation of the data, it is necessary to assess the risks associated with loss of data and/or misinformation in a certain period. As a rule, it is applied three-level protection against such risks [6]. The most severe (disastrous) risks are ones with a high probability of penetrating all levels of protection. Regardless of the group of the risk, it may occur when it breaks three levels of protection. Therefore, the probability of risk occurrence will be equal to the product of three factors:

1. The probability of a risk occurrence (marginal risk) after the break of the first barrier.
2. The conditional probability of risk occurrence (critical risk) after the break of the second barrier.
3. The conditional probability of risk occurrence (disastrous risk) after the break of the third barrier.

Besides, it is necessary to assess whether the probability of risk penetrating each level can be reduced. This is important for the calculation of the budget and its distribution between the three levels of protection.

Efforts aimed at reduction of risk occurrence should be focused not on investment of resources into response measures (often useless) but on their employment for preemptive actions and reinforcement of sustainability [3].

Besides, it is important to regard the relationships both between levels of protection, and various kinds of risks, which can act as a compromise or a synergy [2].

For quantitative assessment of the competitiveness of high-tech products, we have developed a specific model based on the integrated use of technique set involving conventional assessment tools together with heuristic methods and scenario simulation.

The main blocks of the model are the block of determining the indices of competitiveness, the block of scenario modeling, and the block of the search for coordinated decisions to improve the competitiveness of high-tech products. The first block of the model provides for the calculation of particular, composite and integrated indices of competitiveness over time for products of an organization and its competitors with regard to the ideal model of product. The calculation uses the projected values of specifications of high-tech products determining its competitiveness, obtained with the use of predictive models. In this block of the model, there is also the assessment of the level of competitiveness of high-tech products of an organization in terms of products of the principal competitor and the degree of its stability with the use of purposely designed rating scales.

The block of scenario modeling is used for the formation of scenarios of development of main external and internal factors of sales of high-tech products in the world (domestic) market, in accordance with which variable parameters of the model and their values are determined. Potential scenarios under consideration are as follows:

- positive (predominating influence of factors which contribute to the increase in the competitiveness of high-tech products);
- neutral (the influence of factors which contribute to the increase in the competitiveness of high-tech products sets off the influence of factors which reduce its competitiveness);
- negative (predominating influence of factors which reduce the competitiveness of high-tech products).

The indices of competitiveness of products of an organization and its competitors are determined for the developed scenarios.

The results of calculations for various scenarios are used in the third block of the model for the formation of options of improving the product specifications with a view to increasing its competitiveness.

In the course of the experiment, the developed model was used as a basis for obtaining the results of the assessment of the competitiveness of high-tech products of an organization and its two competitors in the implementation of different scenarios are presented in Table 1.

Information presented above can be used to draw the following conclusions. In the neutral scenario, the model of high-tech products of an organization is more competitive as compared to products of competitors due to a high value of the indicator of economic competitiveness. At the same time, it is inferior to the products of competitors in terms of specifications, as evidenced by the lower value of the index of technological competitiveness. In the negative scenario, the model of high-tech products of an organization loses the lead, being inferior to the products of competitor 1 in terms of the integrated index of competitiveness, the lag in the technological competitiveness increases. In case of the implementation of the positive scenario, the model of high-tech products becomes increasingly superior in the sense of products of competitors in terms of the integrated index of competitiveness, but it fails to surpass products of competitors in terms of technological competitiveness.

The results of calculations made for the developed model allow making reasonable management decisions to improve the competitiveness of high-tech products, in particular, assessing alternative versions of design solutions according to the functions of the product and their influence on its competitive price for the selection of the best of them.

The example under consideration was used to solve the task of the search for options of improving specifications of high-tech products of an organization with due consideration of the influence on economic characteristics in order to increase the level of its competitiveness.

Therefore, the scientific novelty of the submitted work consists in:

- the development of an original method for the selection of key indicators for the formation of a set of predictors that consists in the dynamic assessment of indicators based on criteria of high sensitivity to external and internal changes, the ratio of technological state of the art to the price, the degree of innovation, the degree of risk, and the consideration of the influence of the external environment which

enable reliable analysis and forecasting of the competitiveness and competitive prices of high-tech products;
- the development of a universal model of the quantitative assessment of the competitiveness of high-tech products based on the formation and analysis of various scenarios that allows forecasting the indices of competitiveness over time, and determining the specifications of products for the intended competitiveness.

4 Conclusions

The article has substantiated the relevance, scientific and practical significance of the problem of MCHTP and the possibility of solving it at a brand-new level in the context of the use of cross-cutting digital technologies by developing a methodological approach to achieving the competitiveness of high-tech products based on predictive analysis. The authors have put forward the method of formation of a set of predictors that makes it possible to timely control and amend decisions for the management of the competitiveness.

The proposed approach allows actualizing and improving the reliability of the assessment of the level of competitiveness of high-tech products and setting forward measures to increase it at different life cycle stages.

This approach provides a solution to both the task of the forward-looking assessment of the competitiveness of high-tech products, making use of the search prediction methodology, and the task of the formation of the intended competitiveness based on the methodology of regulatory and target prediction by means of scenario modeling of factors which determine the product competitiveness.

Acknowledgements The study has been conducted as part of project No. 1 “Analysis of the preparedness of the Russian society for digitalization” within the donation agreement No. 1154 as of March 01, 2019.

Robotization in the Economy

Alexey V. Zaitsev, Marina V. Bukhtoyarova, Snezhana V. Atoyan, and Natalia V. Mokrova

Abstract The aim of this work was the need to show that robotics and artificial intelligence in the modern economy have become not only its integral part, but, without exaggeration, its very foundation. In our world of high speeds and lack of time, the need for intelligent assistants is becoming ever more acute. As you know, demand creates supply, and now processors that only the "chosen ones" saw thirty years ago are firmly registered in our home. Each house has a washing machine, which is based on a processor, which in terms of computing power is many times superior to the processor that stood on the spaceship that delivered the Americans to the moon. Processor technology has become so commonplace that many very original devices can even be created by a group of school-age children under the guidance of a teacher. The methodological basis of this work is a review of the current level of robotics using the example of the Sberbank Robotics Laboratory. The results of the analysis of the situation taking shape at the forefront of the robotics front of the economy are presented. The basis of the development of the robot model is a mathematical analysis of radio engineering signals that transmit information through its "nervous" system. The result of the work is the obtained theoretical analysis of the technological parameters of the robot, the economic feasibility of certain technical solutions adopted in the manufacture of the prototype is weighed and refined. In conclusion, it should be noted that the application of the capabilities of mathematical modeling of the processes of the electronic components of the robot, including the Fourier transform, made it possible to first create a theoretical, and

JEL Classification O30 · O31 · O33

1 Introduction

Robots are gaining economic space more and more rapidly. This is understandable, as the robot is more economically profitable than a living employee. The robot does not need to be paid for sick leave, it does not need a weekend or a vacation. And a salary is not necessary in general. Also, there won't be any problems with rights violations, as the latter do not simply exist. Thanks to these advantages and the development of mechatronics, robots are penetrating new areas of activity more and more, coming to replace the man.

Let us turn to the authoritative opinion in order to have an idea of specialists' view on digitalization of economy, namely on robotization: "Over the last couple of years, we have often heard the words "digital economy", "industry 4.0" and others. This means that the projects of yesterday's advanced edge of science are now dissolving into familiar business processes. This is natural, this is how development works: everything that can be simplified will be simplified. And in this context, IT and robotics play a crucial role as growth drivers for leading economies. A study by Sberbank's Robotics Lab clearly illustrates the dependence of economic indicators and the level of well-being of citizens on the degree of penetration of information technologies in people's lives"—this opinion was shared with the Robotics Lab by Alexander Tormasov, PhD in technical sciences, University of Innopolis [1].

2 Methodology

At the end of 2017, a new unit appeared in Sberbank—a laboratory of robotics, which was headed by Albert Yefimov, who had previously headed the Skolkovo Robotics Centre for many years. The need to create this unit is caused by the fact that the increasing volume of work and quality requirements can no longer be met by human resources alone. It is necessary to reach a new level—the level of artificial intelligence. Annually, Sberbank processes (sorts, checks) 80,000 tons of money, so the first place is given to collaborative industrial manipulators—robotic money recalculation area. Given the super-volumes of processed money, it is difficult to overestimate the role of such an assistant. According to data for 2018, Danish manipulators "Universal Robots" are used now in Sberbank, but the development of their own collaborative manipulators was already underway.

The second direction is logistics robotics. Sberbank must provide fail-safe logistics to 300,000 people, each about 20 kg of cargo monthly. Therefore, advances in this direction are in great demand.

The third direction is unmanned air and ground vehicles. As it turned out, the main problem with transporting money in Russia is not roads, but bridges. Where there is a straight road 10–15 km long, it can take a collection vehicle 5–6 h to cover this distance. That is why there is a need to develop unmanned vehicles, first of all those that fly.

In spring 2019 at the Skolkovo exhibition, Sberbank's laboratory presented a sample of an unmanned helicopter designed to deliver money with a total weight of up to 5 kg, which is a very tangible amount and is quite sufficient for small areas that are difficult to reach.

The fourth direction is personal service robots, that are voice assistants based on artificial intelligence, which exist in the form of an application in almost every smartphone (for example, "Alisa"), but have not taken place as a separate device yet. According to data for 2017, Russia is the twelfth in the world to produce such systems, fifteen times inferior to the leader—the United States.

These days, when you call Sberbank, you will be answered by an employee, only not a living person, but an artificial intelligence, which is able to recognize the meaning of simple questions and give the necessary answer. The use of such intelligent systems allowed to sharply reduce the staff of the call center, but it is still early to abolish—not all situations can be understood by artificial intelligence.

Truly fantastic results were achieved by developing a digital TV presenter Elena, a copy of a real TV presenter. The digital image is characterized by mimics, light body movements. A little roughly synthesized speech is the only thing that gave out a substitute for a live TV presenter. Apart from that, the artificial intelligence and the living mind were virtually indistinguishable.

The fifth direction is the exoskeleton. At the exhibition in Skolkovo a smart chair was presented, which is a closed pneumatic system. But, despite simplicity of the design, it is rather difficult to overestimate its merits as in a condition of the limited space when it is impossible for the employee to put a chair or when it is necessary to be in a semi-sitting position for a long time, the exoskeleton takes on weight of a body of the person, unloading legs. Of course, this has a positive impact on staff health [4].

Let us now consider one of the examples of robot deployment—a search robot. It is a robot equipped with one or more video cameras, the signal from which is recorded and/or transmitted to the dispatcher—the operator who controls the robot. The purpose of such robots is extremely broad, because they can, due to their small size, penetrate into places where a person can hardly or cannot penetrate at all, and sometimes it is simply dangerous. Such robots find application in archeology—when discovering ancient premises that have been isolated from the environment for a long time, this robot is the first to explore the space for safety.

In disaster medicine, robots like these help find people under rubble after earthquakes or gas explosions, showing rescuers the way to work. Also, these robots save a

lot of money when searching for breakdowns in heating pipes or water pipes. Underwater research is carried out to find minerals, survey the condition of oil production platform supports and bridges running on the seabed of gas pipelines, which Russia has been actively building in the past few years.

Such a robot is developed by a group of Zhukovsky technical school students. The development is at the final stage, it is left to eliminate inaccuracies in the program and to replace the temporary equipment fixtures with the permanent ones.

The robot is a four-wheel-drive platform powered by four TGP01D-A130 motors running in parallel on each side. As a result, the robot rotates according to the caterpillar tractor principle, with the propeller of one side rotating in one direction and the propeller of the other side either stationary or rotating in the opposite direction. This made it possible to abandon the steering mechanism, which is difficult to implement and therefore expensive. All the more so because by turning the wheels in opposite directions, you can turn around in one spot. This makes it easier to control when it is done remotely or via a video camera.

The engines are powered from a separate power source, which is a lithium polymer battery of 11.1 V through powerful transistors—current amplifiers. A pulse-width modulated signal (PWM signal) from the analog output of the processor is fed to the control electrodes of the transistors (base). PWM signal is a sequence of pulses with constant period T and variable time duration τ. The ratio of pulse duration τ to the duration of period T, called duty cycle, is denoted by the English letter Q. By changing the parameter τ, if T is invariable, we obtain a change in the parameter Q-pulse sequence duty cycle. This is a very important parameter, as it can be used to calculate the average voltage over a period—i.e. the actual voltage value. Let us use the integral formula for this (Fig. 1):

$$U_{cp} = \frac{1}{T}\int_0^{\tau} U(t)dt$$

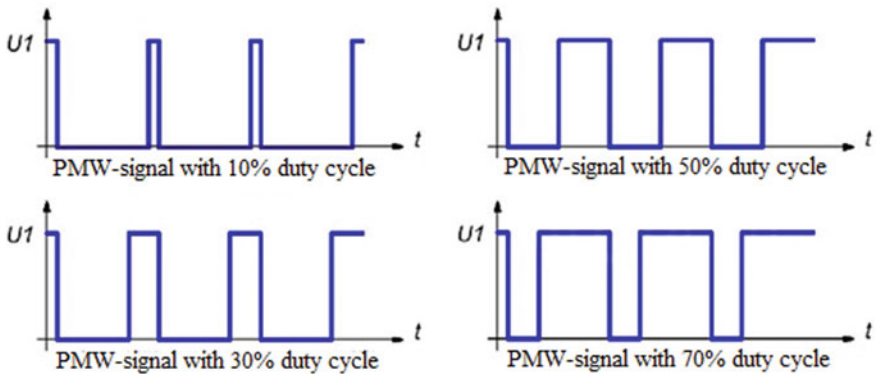

Fig. 1 Multi-dimensional drawings of PMW signal with different duty cycles

For the sequence of pulses of rectangular shape, we have:

$$U_{cp} = \frac{1}{T}\int_0^{\tau} U_m dt = \frac{1}{T} U_m t_0^{\tau} = \frac{U_m \tau}{T} = Q U_m,$$

where $U_m = 11.\text{V}$;

$$U(t) = U_m;$$

T is period;
τ is pulse duration;
Q is duty cycle—ratio of impulse duration to repetition period.

Let us now consider the process of voltage regulation by changing the lduty cycle in more detail. It is well-known that the spectrum of the signal is finite when the signal is infinite and the spectrum is infinite when the signal is finite in time. In our case the signal is an infinite sequence of finite pulses.

The periodic signal can be presented in a form (Fig. 2):

$$f(t) = f(t + T),$$

where

t is time;
T is repetition period.

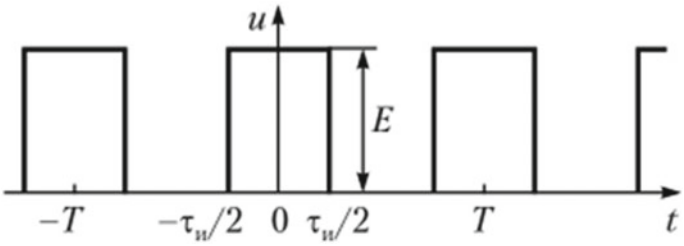

Fig. 2 Sequence of rectangular pulses

In the form of a trigonometric row, this signal looks as follows:

$$f(t) = \frac{a_0}{2} + \sum_{k=1}^{\infty} (a_k \cos k\Omega_1 t + b_k \sin k\Omega_1 t),$$

where

$$a_k = \frac{2}{T} \int_0^T f(t) \cos k\Omega_1 t dt;$$

$$b_k = \frac{2}{T} \int_0^T f(t) \sin k\Omega_1 t dt;$$

$$\frac{a_0}{2} = \frac{1}{T} \int_0^T f(t) dt.$$

For a sequence of rectangular pulses, these formulas will look the following way:

$$\frac{a_0}{2} = \frac{1}{T} \int_{-\frac{\tau}{2}}^{\frac{\tau}{2}} U dt = U \frac{\tau}{T},$$

$$a_k = \frac{2}{T} \int_{-\frac{\tau}{2}}^{\frac{\tau}{2}} U \cos k\Omega_1 t dt = \frac{2U}{k\pi} \sin k \frac{\tau}{T} \pi,$$

$$b_k = 0.$$

Voltage:

$$U(t) = U\left(\frac{\tau}{T} + \frac{2}{\pi}\left(\sin \frac{\tau}{T}\pi \cos \Omega_1 t + \frac{1}{2} \sin 2\frac{\tau}{T}\pi \cos 2\Omega_1 t + \frac{1}{3} \sin 3\frac{\tau}{T}\pi \cos 3\Omega_1 t + \ldots\right)\right).$$

As can be seen from the formula, the signal represents an aggregate of constant component and harmonics, multiple of pulse repetition frequency [5].

It is not difficult to guess that the harmonics are not involved in the work of the engines, but only cause the engine to heat up, thereby reducing efficiency, which has to be tolerated. But fortunately, the energy loss from the harmonics is not significant (Fig. 3).

The supply voltage U, which is delivered to the engines via transistors, is 11.1 V. In this case, the transistor bases are supplied with voltage from the CPU signal,

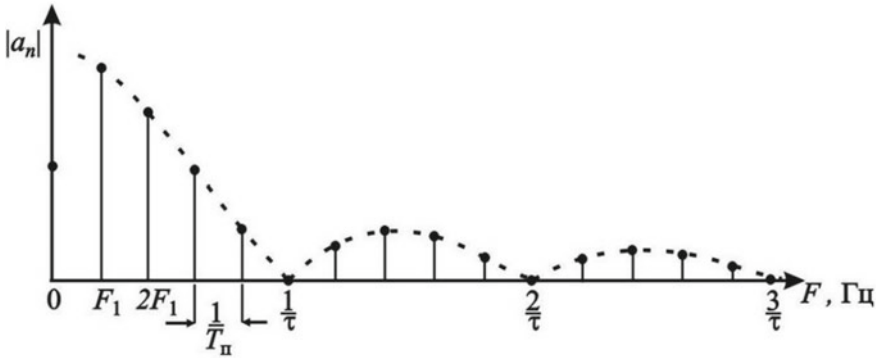

Fig. 3 PWM spectrum

which cannot give more than 5 V. This is achieved by switching on transistors with a common emitter (CE) circuit where the transistor stage has both current and voltage (power) signal amplification. Therefore, by feeding 5 V into the transistor's base, it is sufficient that its operating point goes into saturation mode and the transistor is fully open. At the same time, almost all of the power supply voltage is applied to the engines, as only a few tenths of a volt drop in saturation mode on the transistor. This mode is also convenient because when the transistor is fully open, when the drop voltage on the transistor is minimal and the current can reach a maximum, the power dissipation:

$$P_{dis} = U_{ce} I_c,$$

will be very low, due to the low voltage U_{ce}— the voltage between the collector and the emitter. In the time interval from τ to T when the pulse is over, the voltage at the processor contact is zero, therefore, the transistor is also closed, the resistance R_{ce} is very high and the current through the collector is negligibly small. Therefore, the power dissipated by the transistor is again very low, but now due to the low current. Thus, the transistor running in pulsed mode will dissipate very little heat, which means that almost all the power going to the engines will reach them. In addition, the transistor will not need a heat sink and will not have to take precautions for fear of overheating and failure of devices [10].

The robot also uses a Power Bank battery with a capacity of 3000 mA/h to power the processor and video camera. The choice in favor of Power Bank was not made by chance, the output voltage is 5 V, which corresponds to the supply voltage of TTL logic and processor. Application of the lead accumulator is not justified by the fact that there is a need to use an additional 5 V stabilizer, as the standard voltage of the lead accumulator is 6 V that inevitably leads to an increase in the cost of the robot. In addition, the cost of Power Bank and lead battery is about the same. The second factor that influenced the decision in favour of Power Bank was the fact that there

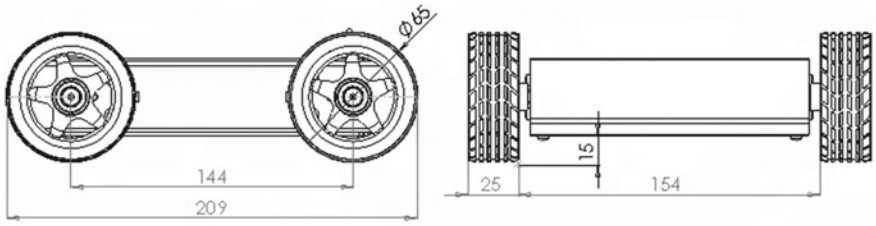

Fig. 4 Drawing of the platform

was no need to purchase a charger—Power Bank can be recharged using a phone charger, which is abundant in almost everyone's phone. This also played a role in cheapening the project.

The platform itself is a rectangle with waste edges of 142 mm × 195 mm. The production material is plastic (Fig. 4).

The first platform had to be ordered in China, in the future it is planned to produce such platforms on its own 3D printer Prusa i3 [8]. This gives the engineers a free hand during the design process when there comes a thought to put this or that type of equipment and a need to slightly change the configuration of the platform. And it's a lot cheaper than that.

The second battery is lithium polymer, 11.1 V. For a long time, its role was played by eight galvanic batteries in series. Of course, from an economic point of view, it was a huge disadvantage, but such sacrifices had to be made, because the smallest relatively inexpensive 12 V lead battery with a capacity of 7 A/h has a weight of more than 2 kg—the platform was noticeably deflected rom it, and the it was clear from the appearance of the motor gears that they would not last long. Eventually, the lead battery was abandoned. That is why the choice was made on the lithium polymer battery as a non-alternative one. It is very light (comparable to the weight of the battery compartment), can give current to the load up to 35 A, which allows the use of very energy-intensive equipment (drilling) on board the robot. Relatively high price (1,850 rubles) is justified by the fact that the battery is designed for 10,000 recharge cycles, so it replaces 80,000 batteries. Therefore, its benefit, even considering that it was necessary to buy a specialized charger Imax B6 at a cost of about 1,000 rubles, is very, very obvious. A simple calculation shows that if we apply the cheapest batteries from Fix Price worth 55 rubles for 10 pieces, one such battery can replace batteries worth 440,000 rubles. And this is without taking into account the fact that the battery capacity is incomparably larger.

The use of the two power supplies is caused by the need to decouple the engines and the electronics from the power supply, because during sharp manoeuvres the engines cause a significant voltage drop, which leads to shutdown of the electronics and stopping the program.

The intellectual basis is the ATmega32A processor from Atmel. Low cost and huge potential were key factors in making a decision in favor of this device. Atmel

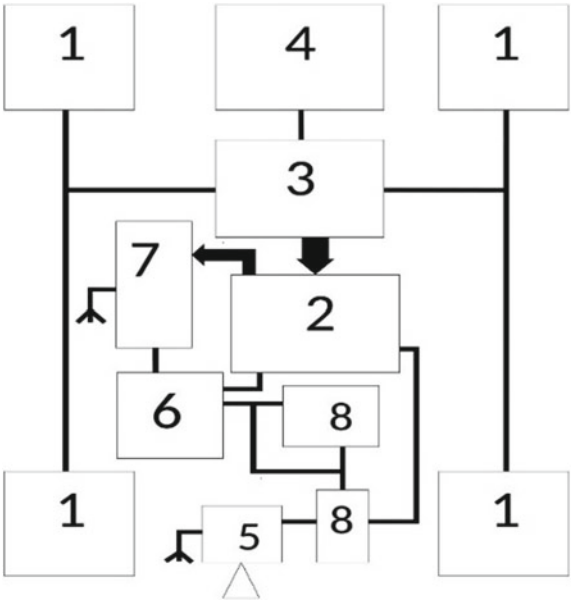

Fig. 5 Structure of the robot

processors are very popular, for them there is a huge number of different programmers, there are a lot of specialists-programmers with whom one can consult in case of a problem, many years of experience of amateurs in the form of ready-made programs allow to adopt someone else's experience or just use it (Fig. 5).

The structural scheme of the robot. Processor (2) receives signals from Bluetooth module HC-06 (7) and controls them through the current amplifier (3), which was discussed above, traction motors (1) and servomotors SG-90 (4), designed to move the camera in the horizontal and vertical planes, respectively. Power is supplied by means of a battery (8), whose voltage is adapted to power the processor and Bluetooth module by means of a stabilizer (6). Video signal is transmitted from the camera (5) via radio channel to "virtual reality" glasses. It can be controlled from any mobile device—a phone or a tablet. When a mobile device is connected to a robot, the program-interface is automatically transferred to the phone memory and then turned on. The program-interface is developed by forces of hobby groups' members [6, 7, 9].

The video camera is arranged in such a way that the radio channel [2, 3] transmits a picture with a low definition (600 lines), while a much higher quality video is recorded on a flash drive.

Tests of the prototype showed that the use of Bluetooth as a radio channel to provide control, is quite effective, and at the stated distance of 10 m, it confidently worked at 20 m. Long distance tests were not carried out, as the size of the laboratory was insufficient.

Further development of the robot is possible, since the central processor is only a few percent loaded, which allows the application of various mathematical methods

of information processing. It is also planned to equip the robot with sensors (temperature, humidity, gassing), as the capabilities of the Bluetooth channel have not been exhausted yet and it is possible to increase the information loading of the channel. Certain consideration is given not only to mastering the signal transmission via Bluetooth, but also to the use of Wi-Fi. The advantage of Wi-Fi is that with its help one can connect the Internet via Wi-Fi Fi router and provide control of the robot from anywhere in the world.

3 Conclusions

The very word "robot" was invented by Karel Čapek back in 1920. But then they only existed on the pages of fantastic stories and novels. Over time, the first rays of hope for the creation of intelligent machines were shining on the horizon. And now in each, even not big on the population of the city, there is a club of robotics, where people sometimes create very intricate creatures, performing commands on the program laid in them. And the robots created by the largest corporations are literally admirable. And their development is moving forward by leaps and bounds. If back in 2010, robotic football players resembled men sitting up late in a bar, today they are professional players who are about to compete players alive. This trend leads to the conclusion that as soon as the economy began to come to a static state, a new direction appeared, which promises to make another breakthrough, not to let the economy stop its development.

The creation of the robot, which was discussed in the article, cost about 10,000 rubles, which is relatively little. Creating a second robot will also cost cheaper, because the experience has been gained and many ways of research have been determined. Thanks to this fact, robots will penetrate into our lives as mobile phones did and will become just as necessary. And it will be hard to imagine how we once lived without them.

Artificial Intelligence Versus Human Intelligence in Socio-Cultural Measurement

Olga F. Morozova, Elena A. Nozdrenko, and Irina A. Panteleeva

Abstract The aim of the article is a comparative analysis of human intelligence and artificial intelligence, as well as the search for a methodological approach that would allow resolving the contradictions that arise between different areas of knowledge in their understanding. It is proved that comprehension of the essence of artificial intelligence reaches a paradigmatic level and the solution of discussion issues at the level of a culture-centric paradigm is proposed. Through a comparative analysis of human intelligence and artificial intelligence, the insufficiency of both the techno-scientific approach to their perception, which significantly narrows the understanding of phenomena and the philosophical approach, which takes science to the level of high abstractions, is proved. It is recommended to switch to the sociocultural dimension of artificial intelligence and human intelligence, which, recognizing the merits of technoscience and philosophy, on the one hand, takes into account the specifics of the sociocultural context and, in this regard, removes the limited perception of artificial intelligence as an element of the technosphere and reveals the numerous connections of the technosphere with other spheres of life society, and on the other—thanks to the last circumstance, it concretizes the philosophical vision of intelligence. Recognizing the highest value of man as the creator of culture and the result of its creation, the authors of the article emphasize that human intelligence, due to the presence of special substrate components that determine its existence in the space-time continuum, is incommensurable with artificial intelligence.

1 Introduction

Work on the creation of artificial intelligence is today an integral part of the objective reality in which a person lives. This has led to fundamental sociocultural changes. It is generally recognized that the issues of the interaction of science and technology occupy a dominant position in all areas of public consciousness, including political doctrines. On October 19, 2019, the President of the Russian Federation approved the national strategy for the development of artificial intelligence until 2030, based on the fact that a monopolist in the field of artificial intelligence can become the ruler of the world. In alliance with genetic engineering technologies, with nanotechnologies, artificial intelligence as a technology can cause irreversible changes in natural and sociocultural spheres and lead to irreversible transformations of the existential dimension of man and humanity, which actualizes the search for approaches to its study that meet modern requirements.

2 Methodology

Due to the versatility of artificial intelligence and human intelligence, the authors of the article use a system of methodological techniques and principles when studying them. The study is conducted in line with the culture-centric paradigm, including the principles of culture-centrism, humanism, continuity, which allowed us to consider intelligence as a cultural phenomenon in all its diversity.

Productive is the use of reflective analysis in characterizing the capabilities of the cognizing subject, as well as the use of philosophical methodology, general scientific principles and approaches, and concrete scientific methodology. When choosing a methodological orientation and orientation in the study of the object, a substrate approach was used that detects elementary formations of intelligence, a structural-functional approach, in which the interaction of the levels of intelligence and its elements becomes apparent. System analysis made it possible to draw a conclusion about the need for a comprehensive knowledge of the possibilities of creating artificial intelligence and the needs of mankind in its creation. A content analysis of theoretical sources was carried out, which showed the urgent need for science to concretize the categorical apparatus, coupled with synchronous and diachronic methods that are relevant for cultural research.

3 Results

The study of the problems of artificial intelligence in modern research lies in the plane of various fields of scientific knowledge. This is due, inter alia, to its penetration into various spheres of human life. In our study, the issue of opposing artificial intelligence to humanity is actualized. And in this regard, we capture various research concepts. Some people believe that artificial intelligence can surpass human intelligence, while others quite clearly transmit the opposite point of view [1]. However, today the phenomenon of "human intelligence" has not yet been fully studied. And this means that the creation of an artificial intelligence system, which should surpass the human one, can itself be called mythological.

Some scientists prove that the formation of a modern techno-scientific paradigm potentially contains the conditions and prerequisites for the transition of all human civilization to a qualitatively different state. At the same time, the algorithms and prospects of this transition are considered by representatives of technical and humanitarian sciences in various ways, which gives rise to an amplitude of assessments and opinions, ranging from optimistic and enthusiastic to pessimistic and frankly negative. We propose to expand the vector of research in the direction of a cultural-centric paradigm, which will not only explain the reasons for this amplitude of opinions, but also help to find a solution to pressing problems in interdisciplinary fields.

Having arisen in the bosom of technical sciences, artificial intelligence goes beyond the scope of technical ontology and becomes a special cultural phenomenon that has acquired not only relative independence, but also the status of a phenomenon that actively affects sociocultural evolution. That is why the attention to the sociocultural dimension of artificial intelligence was updated.

The sociocultural dimension involves the recognition of artificial intelligence as a value. The axiological approach is preceded by an awareness of the positive and negative aspects of artificial intelligence. According to M. Naumov and A. Chistyakov, the creation of artificial intelligence opens up completely new frontiers for development for humanity [2]. And it's hard to argue with that. The authors highlight some exceptional features of artificial intelligence: (1) the ability to control and reduce incoming large amounts of information in real time; (2) the ability to make decisions in the face of a lack of time and complex tasks; (3) the ability to coordinate decisions with other parts of the process or object; (4) the ability to maintain and disseminate the knowledge gained as a result of many years of work by experts.

A positive forecast for the development of artificial intelligence in terms of its superiority over human, we found in the work of O. Basalaeva "Features of the relationship of intellectual culture, artificial intelligence and the creative process". The researcher states that a person is a biosocial creature and "not one of the androids has full autonomy yet, an almost complete copy of a person will certainly appear in the not so distant future" [3]. The author predicts qualitative changes in human culture, namely the unity of technology, information and culture in a situation of more advanced artificial intelligence.

Aware of the increasing capabilities of technology, a number of authors introduce the concepts of "weak" and "strong" artificial intelligence. Properties that a strong AI should possess, at least equality to human intelligence, self-awareness (reflection); ability to experience feelings [4]. We draw attention to the fact that Western science has formulated two hypotheses, where the levels of artificial intelligence are reflected in the concepts of strength and weakness: "strong artificial intelligence" and "weak artificial intelligence" [5].

Other researchers introduce the concept of "real" artificial intelligence. The authors believe that "despite the enormous complexity, it is necessary to pose and try to solve the problem of creating a" real "AI, having a body corresponding to its" specific "intelligence and realizing all the functions required for its existence in its specific environment and to fulfill its purpose" [6]. Understanding that this is not natural intelligence, the goal is to use the beneficial "finds" of nature for its environment, for survival [7]. Namely, when creating a "real" intellect, the authors propose the expediency of using the natural principle of minimality, which postulates the minimization of the expenditures of the main natural resources (space, energy, time) when any creatures commit it.

A. Karpov, predicting the further active development of AI systems, notes both positive and negative points. Among the positive aspects stand out: facilitating the routine performance of work; a significant increase in the standard of living of a person by reducing the cost of goods that are created using AI; delivering truthful and reliable information is a useful function in politics and the media; AI systems can take part in solving problems dangerous to humans. Of the negative aspects, the author determines: the ability to lose work due to the replacement of the AI functionality; fears that AI will become "extremely" smart and will be able to kill or enslave humanity; the impossibility of the machine to independently determine the benefits or harm to humans. In this case, we agree with the author that "scientific and technological progress cannot be stopped, and if the supermind is destined to appear, it will appear" [8]. However, one can discuss the degree of its implementation in all spheres of human life and effectiveness regarding the capabilities of human intelligence.

For the humanities, the highest criterion for development is man as a qualitatively unique phenomenon that actively exchanges information, like other living things, and has a psyche that allows it to coexist with its own kind, but it is also a bearer of reason capable of abstract thinking. Man is the only bearer of intelligence on the planet and at the same time the creator of the "second nature"—culture, he lives in the noosphere (the sphere of the mind) artificially created by him, and by this he should be preoccupied with the correlation of his intellect and artificial intellect.

Despite the rather frequent use of the concept of "intelligence", it turned out to be difficult to define intelligence as a phenomenon. Submitting the trends of differentiation of scientific knowledge, scientists began to distinguish various approaches to its understanding. Following M. Kholodnaya in all the abundance of special literature, several approaches can be distinguished: (1) phenomenological, in which intelligence is associated with the content of human consciousness; (2) genetic, illuminating the consequences of the increasingly complex adaptation of man to the environment;

(3) information, which demonstrates the processes of information processing; (4) process and activity; (5) structural-level; (6) regulatory; (7) ethological [9]. In line with our subjects, special importance is attached to the sociocultural approach.

In a broad sense, intelligence is defined as a kind of integral characteristic of human consciousness that allows adapting to living conditions, solving life problems, and focusing on a wide field of information, one of the ways to acquire knowledge, the individual's global ability to make rational behavior in the environment, and much more.

A. Migunov defines the human mind as "a systemic property of a community of individuals with highly developed brain matter organized into a single organism through the discourse in which the mind is born and reproduced. The mind is not produced by nature, the brain. It is a supernatural phenomenon and in this sense is always artificial" [10].

Thus, when solving the problems of creating artificial intelligence, we come to the need to correlate the phenomena of "intelligence", "human mind", "human thinking", "a set of logical algorithms of machines" and "consciousness". The unambiguity in the definition of these terms has not been achieved and within the framework of this article we do not pose such problems, we note only some nuances necessary to clarify the author's position.

In the light of the substrate approach, we pose the question: can artificial intelligence be considered as artificially created consciousness? The initial postulate for us is: consciousness is a characteristic way of reflection in humans. Science has already moved away from the one-dimensional concept of consciousness and moved on to its multi-level understanding. It is not only about the unity of the ordinary and theoretical, often understood as rational, fixed in concepts, judgments, conclusions, laws, theories, and pictures of the world. Consciousness is spoken of as the unity of psychic, mental structures and intelligence proper [11].

We believe, firstly, that consciousness is a phenomenon that has its roots in the "first nature" and flourishes in the "second nature". In a certain sense, it is also a sociocultural phenomenon, in the ontological plan, inseparable from the evolution of culture, taken in the unity of the material, physical and spiritual. Artificial intelligence is a phenomenon of the "second nature"—culture, the phenomenon of material culture and the nature of the relationship with physical and physiological processes is problematic.

Secondly, it is unlawful to identify consciousness with processes occurring in the human brain, and in this sense it is not identifiable with artificial intelligence. We do not fully share the position that even if the rules by which the human brain "works" can be known, this will give rise to the possibility of their full programming. Reasoning about the latest developments in the field of artificial intelligence raise the question of civilizational transformations of the modern world. "Computers with superintelligence work millions of times faster than humans. They are accurate, economical and devoid of the emotions inherent in man. Nevertheless, we are talking only about analogues of the most complex and most perfect work of nature—the brain, with the help of which a person is able to think outside the box and creatively, in contrast to artificial intelligence" [12].

Given that a person is a bio-social being, with a sociocultural approach, it becomes important not only to analyze the possibilities of copying human biology. Here, an ongoing discussion has been outlined both about the possibilities of creating artificial intelligence, and about the advisability of "copying" a person in a "machine body".

On the one hand, projects that seemed fantastic no longer seemed so thanks to techno-science—a new phenomenon in spiritual culture. The border between fundamental and applied knowledge in techno-science is more and more blurred, on their basis a "techno-scientific complex" is created, which offers a number of "converging" technologies (NBIC). The combination of nano-, bio-, info-, cognitive technologies, as optimists believe, will help the artificial recreation and modification of man.

On the other hand, work in the physiology-cybernetics tandem demonstrated a clear lack of knowledge about the essence of the mental processes of the human brain. The brain remains the only human organ that has not yet been learned to replace with an artificial analogue, and the imitation of certain physiological properties of the brain has not led to a significant breakthrough in solving the problems of creating artificial intelligence.

Thirdly, when considering the "consciousness-brain" relationship, we are neither supporters of the concept of the brain and consciousness as independent entities, nor the straightforward determination of consciousness by the brain, nor psychophysiological parallelism, nor vulgar materialism that identifies consciousness with material substance. We believe that the essence of consciousness should be considered in the aspect of the dialectical unity of substance and substrate.

Fourth, having a very definite essence, consciousness finds manifestation "outside", i.e. in the behavior and interpersonal interactions of people, fixed in the norms, methods, rules of communication and in the ability to adapt to social conditions and integrate into the system of sociocultural relations.

Based on the foregoing, consciousness and intelligence, firstly, are not identical, it cannot be argued that artificial intelligence is an artificially created consciousness. Secondly, non-identity does not mean their mutual exclusion. If we proceed from the definition of man as homo sapiens—a rational person, then intelligence can be represented as the quintessence of consciousness.

In modern literature, the concept of "leveling" has become used in relation to intellect, although there is no sufficiently definite criterion for achieving "rationality". Immediately, we note that the leveling of artificial intelligence has a mainly quantitative dimension, and qualitative indicators are inherent in the levels of human intelligence. The definition of quality, as an internal certainty identical with being, makes us turn to the hierarchy of structures of human intelligence.

This hierarchy is built taking into account the fact that man and machine live in "different worlds". The "world of the machine" is limited by the physical parameters set by the person, strict logical laws and the logic of identity rule in him. The vector of the machine is also predetermined by man. The world of man is unlimited, many-sided, there are countless links and relationships in it. A person (in this we agree with the teachings of existentialists) is constantly in a "borderline situation" and must make a choice in the field of tension of similar situations, acting in the logic of analogies. His activity is not just multi-vector. These vectors are inside the system.

Indicators of the level of human intelligence are the speed and completeness of the analysis of external factors, a critical assessment of the situation and oneself (self-reflection), the wealth of associative connections that an individual attracts to make a conscious decision and search for alternatives. *This implies the need for a systematic analysis of all levels and segments of human intelligence.*

Just as the existential psyche, mental feelings and intellect stand out in the mind [11], we consider it legitimate to refer to the hierarchy and relationship of emotions, mentality and rationality that exists in the human intellect.

For a long time, when creating artificial intelligence, the emotional component of consciousness was not taken into account and only after almost half a century did they begin to pay attention to its importance in the movement of information flows. The ability to perceive and understand a person's feelings, other people's emotions, skills to manage feelings and emotions, emotional stability are called "emotional intelligence" [13]. The components of emotional intelligence are called intrapersonal skills, the ability to understand their emotions and manage them. Here the foundations of elementary reflection, self-esteem, emotional self-analysis, that is, the ability to differentiate one's feelings into positive and negative, are laid.

For a person, the skills of interaction with others are also important, in particular empathy (the ability to understand the feelings of other people), the ability to establish and maintain relationships with other people that are not characteristic of the machine. For artificial intelligence, the components of adaptability and a positive attitude to life are also not needed.

Moreover, the emotional component of human intelligence is actively involved in creative processes. In the process of creativity, a person is able to abstract from the details of the external world (the machine is characterized by a mechanical perception of details) and embrace reality as a whole, distributing the elements of reality harmoniously. And this aesthetic feeling, a sense of harmony not only satisfies our aesthetic needs, but also makes it possible on an emotional level to intuitively approach the discovery of the laws of the world at the level of rationality.

For a more specific understanding of the difference between artificial intelligence and human intelligence, we found it possible to turn to such a phenomenon as mentality, since culture is "encoded" in mental structures. It is thanks to the mentality that a person develops an original way of thinking, and according to English psychological dictionaries, mentality is "the ability or power of the mind". Although the mentality is not recommended to be identified with the archetypal inheritance, we note that the machine cannot be characterized by the "pralogic thinking" characteristic of a person [14], a peculiar stock of features and manifestations of mental properties, attitudes. As an integral characteristic people living in a particular sociocultural locus, the mentality determines the peculiar vision of the world and how to respond to the natural and social environment and adaptive mechanisms. Just as the existential psyche, mental feelings and intellect stand out in the mind [11], we consider it legitimate to refer to the hierarchy and relationship of emotions, mentality and rationality that exists in the human intellect.

For a long time, when creating artificial intelligence, the emotional component of consciousness was not taken into account and only after almost half a century

did they begin to pay attention to its importance in the movement of information flows. The ability to perceive and understand a person's feelings, other people's emotions, skills to manage feelings and emotions, emotional stability are called "emotional intelligence" [13]. The components of emotional intelligence are called intrapersonal skills, the ability to understand their emotions and manage them. Here the foundations of elementary reflection, self-esteem, emotional self-analysis, that is, the ability to differentiate one's feelings into positive and negative, are laid.

For a person, the skills of interaction with others are also important, in particular empathy (the ability to understand the feelings of other people), the ability to establish and maintain relationships with other people that are not characteristic of the machine. For artificial intelligence, the components of adaptability and a positive attitude to life are also not needed.

Moreover, the emotional component of human intelligence is actively involved in creative processes. In the process of creativity, a person is able to abstract from the details of the external world (the machine is characterized by a mechanical perception of details) and embrace reality as a whole, distributing the elements of reality harmoniously. And this aesthetic feeling, a sense of harmony not only satisfies our aesthetic needs, but also makes it possible on an emotional level to intuitively approach the discovery of the laws of the world at the level of rationality.

For a more specific understanding of the difference between artificial intelligence and human intelligence, we found it possible to turn to such a phenomenon as mentality, since culture is "encoded" in mental structures. It is thanks to the mentality that a person develops an original way of thinking, and according to English psychological dictionaries, mentality is "the ability or power of the mind". Although the mentality is not recommended to be identified with the archetypal inheritance, we note that the machine cannot be characterized by the "pralogic thinking" characteristic of a person [14], a peculiar stock of features and manifestations of mental properties, attitudes. As an integral characteristic people living in a particular sociocultural locus, the mentality determines the peculiar vision of the world and how to respond to the natural and social environment and adaptive mechanisms. The formation of mental structures is determined by sociocultural factors.

The transition to the next level of human intelligence required the use of the term "information". Without going into details of the structure of artificial intelligence, we note an important circumstance for us—artificial intelligence contains and transmits information. The information field he is creating is currently huge and complex. But all types of information are characterized by an essential feature—the information transmitted by the machine in terms of content is objective knowledge.

The issue of objectivity of knowledge plays a special role in discussions about the phenomenon of "artificial intelligence". In this sense, the theory of artificial intelligence is defined as "the science of knowledge, how to obtain it, represent it in artificial systems, process it inside the system and use it to solve problems" [15]. I. Lysak, interpreting knowledge in artificial intelligence, believes that "a serious problem in creating expert systems is the problem of representing knowledge for processing it in a machine, as well as the problem of search" [16]. Obviously, the difficulties of acquiring knowledge in artificial intelligence are associated with the

complexity of studying the structure of expert knowledge and the mechanisms of its functioning. I. Alekseeva calls the approach to knowledge used in artificial intelligence to be technological [17]. Therefore, we can say that in artificial intelligence we can talk only about formalized knowledge. And this means that the decisive role in the effectiveness of expert systems is related to the degree of formalization of knowledge. Then human intellect belongs to the epistemological interpretation of the category of "knowledge"; artificial intelligence relates to knowledge from a technological perspective.

Drawing an analogy between artificial intelligence and human, D. Gasparyan believes that the interpretation of artificial intelligence is based on the identification of meaning and meaning. The author's key thesis is that "human intellect easily distinguishes between meaning and meaning, understands sentences directly about meaning and … even if he does not resort to such proposals directly, he constantly uses them as a background or context, as well as a formal condition for particular acts of understanding. But, as it seems, not everything will go so smoothly in the case of machine intelligence" [18]. It is rightly noted that a new level of discussion about the specifics of artificial intelligence is possible provided that there is final clarity in understanding the essential meanings of categories such as "meaning" and "understanding". Perhaps, here we agree with the author in the position that "the creation of thinking (in a fully anthropomorphic sense) robots is possible, but not in our human world" [18].

The cognitive component of human intelligence is subjectively colored by evaluative and instrumental acts of consciousness. This circumstance gave rise to the desire to introduce a concept that will characterize only human intelligence—academic intelligence. The content of academic intelligence includes the presence of a certain amount of knowledge, erudition, the ability to solve logical problems, find the optimal solution to problems not only according to formal logical laws, but also involving dialectic logic. We would put it more specifically: the academic intelligence of a person has allowed us to create a special cultural phenomenon—science and its inherent scientific rationality.

If we consider scientific rationality in a sociocultural context, it turns out that the invariant core expressing the features of scientific research itself in each type of rationality merges with a special interpretation [19]. The scientific rationality of man has historically shifted from the study of simple systems to difficult to regulate and to complex ones. Thus, an idea appeared about the features of system organization, which are either non-formalizable or formalization "coarsens" and fragmentes an object. For artificial intelligence, the ideals and norms of scientific thinking that have "epochal" content are not applicable—how to explain, describe, build a system of evidence and create a structure for building knowledge.

And finally, the methodological reflection of the activity of the knowing subject—a person—is carried out using the philosophical level of analysis and taking into account the level of its methodological culture. Although artificial intelligence has a short history, it is nevertheless obvious that it is "non-historical." It acts "here and now", and the academic intellect of a person is not limited and turns into an object even that which could potentially become the subject of human activity. The space

and time of culture "unfolds" the process of thinking in a concrete direction and what we call the "standard of rationality", the "project of science" is formed.

Thus, being an integral element of a person's social intellect, an internal deep psychological sociocultural attitude, mentality influences the whole worldview system, which, in turn, as a system of a higher order, determines the types of rationality. So the "knowledge chain" moves from the classical type of rationality to the non-classical and post-non-classical types.

The most important aspect of the problems we study is the ethical problems of the functioning of artificial intelligence [20]. The fact that artificial intelligence systems increase the efficiency and effectiveness of companies by eliminating errors due to the human factor can be recognized as indisputable. However, according to I. Rudakova and N. Polyakova, "at the present stage several problems have arisen in the field of the ethics of using artificial intelligence: employment of the population, which lost jobs due to the replacement of manual labor by machine; the use of new technologies for military purposes against humanity; programming electronic media based on non-tolerant stereotypes, including racial prejudice" [21]. In this regard, the issue of creating ethical codes, which, inter alia, will allow the use of artificial intelligence systems for the benefit of mankind, is being updated.

If we leave optimistic statements about the possibilities of technoscience outside the scope of the article, the question of goal-setting still remains open. The idea expressed by I. Frolov "To create a person smarter than us, we should already be smarter than the one we want to create, including possess higher morality!" [22]—the scientific humanists picked up. We believe that there is no and cannot be an ethical dimension of artificial intelligence, and this clearly follows from the presence of such a component of human intelligence as social intelligence. While the machine exists and functions without regard to the social environment, a person has special needs—the need for social experience.

Social intelligence is understood today as a systemic personal quality, the presence of abilities that provide not only the adaptation of a person in society, but also its active integration into social relations: interpersonal, professional, political, economic, etc.

Human social intelligence contains at least three components—cognitive, behavioral and emotional. It is noteworthy that the level of academic intelligence does not correlate with the level of social intelligence and its presence is not a guarantee of social success. The sources of development of social intelligence are: (1) the presence of constants of the sociocultural locus; (2) the unity of social and individual experience, ensuring the internalization of sociocultural norms, values, socialization and inculturation as a whole; (3) aesthetic activity, art.

The human sciences reveal three vectors of his interactions: the appropriate "integration" into the natural world, the creation of the "second nature" and functioning in it, as well as what is directly related to the problems of creating artificial intelligence—the task of preserving oneself as a rational being and providing for one's own further progressive development.

Artificial intelligence contains, albeit a large, but a certain amount of encoded information. But a person has several "programs": in addition to the genetic program, there are sup-biological ones: a sociocode and a cultural code, which in themselves

are very complex and multidimensional formations reflected in the corresponding competencies.

Comparing artificial intelligence and human intelligence, we pay attention to another problem that is not comprehended by the science of artificial intelligence—the problem of the chronotope of artificial intelligence, that is, the understanding of the existence of artificial intelligence in space and time. Convincing, in our opinion, is the position of T. Chernigovskaya, who believes that "… we have not yet seen artificial intelligence, which would be Mozart or Shakespeare. When it comes to trillions of operations per second, it is clear that now this is already inhuman temporal space. Our brain is arranged differently than modern computer systems, but with the advent of quantum computers working on different principles, we will find ourselves in a completely different world" [23].

Human intelligence develops on the basis of sociocultural conditions. Therefore, the level of human intelligence depends on the degree of awareness of the characteristics of universal and national culture, spiritual and moral foundations of life. At this level, knowledge of historical memory, the development of cultural heritage, and the experience of previous generations are recorded. Here, behavioral patterns are created corresponding to either the behavior of historical figures, cultural figures, or the immediate environment. The presence of this intelligence sector opens up the possibility of interaction with representatives of other cultures, religions, languages. A dichotomy of "friend or foe" is characteristic of a machine, excluding manifestations of tolerance, cosmopolitanism, humanity, respect for the rights and freedoms of another.

In the spatio-temporal aspect, artificial intelligence "lives" in the present, the perception of the past, present, future is also formalized. Only man is characterized by a dialectic of the manifestation of intelligence at three levels: the level of potential opportunities realized under certain sociocultural conditions; level of actualized abilities determined by sociocultural practice; level of predictive capabilities. It is not only the construction of possible options that is characteristic of a person, but also imagination—the ability to put oneself in a real or virtual social context and predict one's behavior in accordance with such "imagination".

A machine lives passively in time; it does not use it. Man in this regard is active. Human intelligence allows him to transform the spatio-temporal form of his being. Man is subject to the time of the sociocultural locus, which prescribes the stages of life. But he, realizing his being, is able to speed up or slow down the stages of the life cycle. The invariance of time of use is manifested in the division of time into working and free, in the choice of options for leisure activities, in the appearance of spatio-temporal management and self-management, and many others.

The machine operates in a well-defined constant sphere and artificial intelligence does not require sphere vision. Human social intelligence models the dialectics of the spheres: economic, political, spiritual, professional, family, etc. Therefore, its content should organically include knowledge of environmental culture, safety rules, and personal hygiene.

The human intellect, unlike the artificial one, has the task of distinguishing between the general and the separate, itself as an individual and the social whole in

its entirety. The specificity of individual mental life and its inclusion in society, the variability of motivation for behavior under the influence of sociocultural dynamics, neither lends itself to imitation or simulation. Of particular note is the analysis of the "language space" of the machine and man. With all the variety of "linguistic" potentials of the machine, the uniqueness of the natural language of man is preserved. As it is well known, the experiment set up in the Chinese room forced scientists to again engage in the relations of syntax and semantics, to rethink the criteria of intelligence.

Communicating with his own kind, a person constantly deals with modifications of the system of values and meanings that are caused by transformations within the sociocultural context. He, but not the machine, is characterized by both verbal and non-verbal interpersonal communication. Elements of non-verbal communication are encoded in the culture of the sociocultural locus and therefore are not subject to simulation. If a person has a systematic intellect, creativity is formed—creative intellectual abilities [24]. For the manifestation of the latter, high moral motivation, an internal feeling of one's own strength and ability to create are required.

Thanks to the systemic perception of the world, which is achieved through the interaction of the emotional, mental and cognitive components of intelligence, a person is able to detect a problem, generate a large number of ideas, be flexible (as opposed to straightforwardness of a machine) when producing various ideal constructions, and choose original methods for solving problems typical of the challenges of the sociocultural era.

Thus, in an era when humanity had a real opportunity to influence the future, to enter new frontiers in human development, increasing the space of freedom, creativity and humanism, there was an urgent need for "science of science" to complement the sociocultural dimension of artificial intelligence, to turn knowledge about artificial intelligence into value culture.

4 Conclusion

1. Artificial intelligence is a fundamentally new phenomenon of human culture. This novelty and the status of artificial intelligence in the system of culture predetermined the need to go beyond its scope of technoscience and move to a broad sociocultural dimension, including axiological aspects.
2. Speech should not be reduced to the technologies for creating artificial intelligence; one should comprehensively rethink not only the possibilities of its application, but also its essence, status in the process of socio-cultural development.
3. The sociocultural dimension involves the additional development of the methodological foundations of scientific knowledge about human intelligence and artificial intelligence against the background of a culture-centric paradigm using the principles of culture-centrism, humanism and continuity.

4. In the light of this methodology, artificial intelligence and human intelligence should not be opposed, since they are inextricably "integrated" into a single sociocultural context.
5. The inability of artificial intelligence to surpass human is obvious due to the incommensurability of the substrate and spatio-temporal parameters of their being. Artificial intelligence systems can significantly facilitate the life of a modern person, allowing increasing the efficiency of his work. But we must admit that without the person himself (his thinking, emotions, sensory perception, etc.), artificial intelligence is not capable of fully functioning.

On the Issue of Legal Support of Public Administration in the Context of Digital Transformation

Leonid L. Grishchenko, Yuliya L. Korabelnikova, and Oleg N. Dyadkin

Abstract It's not a secret to anyone that the twenty-first century is characterized as a time of information transformation, and more recently, of the digitalization of all spheres of management. Digital technologies are being introduced into our lives all existing spheres, for example: politics, social sphere, economy. At the international level, the issues of digitalization are receiving the closest attention. In the Russian Federation, as we see, only the first, timid steps are being taken in the regulation of public relations in this area. This is due, first of all, to the facts that to date, legal scholars and lawmakers haven't sufficiently decided on the concept of «digitalization». This also led to the fact that Russian legislation doesn't have a coherent, clear legal regulation of these issues, and therefore, relevant government authorities are only launching test sandboxes in test mode in order to study law enforcement practice in the area of digitalization of industry, education, medicine and other areas in order, on the one hand, to prevent violations of the law, and, on the other, to achieve effective legal regulation. This position led to a contradiction between the need for further progress in the area of digitalization and the imperfection of the legal support of public administration in the current conditions, which requires immediate correction. The purpose of this article is to identify gaps in the legal regulation of public administration in various spheres of life and formulate proposals aimed at addressing them. The research methodological base was composed of: universal scientific methods: the general scientific dialectic method of cognition, other special methods for studying social and legal phenomena and processes: formal-logical; systemic; complex; concrete sociological.

1 Introduction

The modern world is very difficult and even, probably, impossible to imagine it without information technology. Digitalization of management today is one of the most frequently discussed phenomena of reality. UN Secretary General Antoniu Gutierash notes that the modern world is on the initial path of development of the digital economy.

It's clear that digitalization has had and will certainly continue to have a global transformative impact on the life, work and development of the global economy [1]. Nevertheless, in the legal field in this area there is a certain vacuum at the moment that has to be overcome both in the international space and in every state that claims to be widely used in digital technologies.

2 Materials and Methods

Russian law hasn't regulated digitalization in various fields yet, despite the fact that this term has been used in Russia since the late 90s of the twentieth century. So, in particular, the Order of the State Committee for Communications and Information «On the Approval of the Rules for Technical Operation of the Primary Networks of the Interconnected Communication Network of the Russian Federation» (Decree of the State Communications Committee of the Russian Federation No. 187 of October 19, 1998) stipulated the need to convert the analog resource to digital.

What makes us appreciate the role of digitalization in the modern world? This circumstance is largely due to the fact that digitalization not only affects the main system-forming public institutions on a large scale, but also actively modifies them [2].

One of the first impacts of digitalization was felt in the economic sphere, which is characterized by a constant increase in digital products. It's noteworthy that most market leaders are adherents of the digital economy at the present time.

Their main values include: «big data», «artificial intelligence», «digital space». All of them provide the opportunity to ensure effective business management at very high speeds, which is one of the determining factors affecting decision making today.

The methodological base of this study was a set of scientific principles, the application of which is determined by the purpose and objectives of the study. First of all,

the research used the method of materialistic dialectics, which allowed revealing the main idea of research in the unity and diversity of its manifestations.

A systematic approach to the study of problems of scientific analysis [3–5] of data on digitalization of public administration made it possible to obtain reliable knowledge about it.

The formal logical approach to the study of the issues of legal support of public administration in modern conditions of digital transformation has made it possible to establish the meaning of framework legal norms and legal gaps in legal regulation in this area.

Using of empirical methods allowed us to effectively solve the research tasks in the course of studying the transformation of public administration in the new digitalization environment.

3 Discussion and Results

Today, the world community is faced with the fact that the usual objects of law (property, land and other natural resources) may cost less than information and methods of processing it. Everywhere we see ads on financial decision-making in a few minutes (approving loans, opening accounts), which allows us to conclude that digitalization provides a significant advantage to their owners.

Many modern studies have been devoted to the study of the digital economy and the work of D. Tapscott should be noted among of it. The scientist identified a significant reduction in transaction costs of information retrieval as the main advantage of this type of economy, the result of which is the exclusion of intermediaries from economic relations. This allows for direct interaction between the consumer and the supplier [6].

Today, many spheres of life are undergoing a fundamental change, a strong place among them is: in the political sphere—electronic polls, polls; in the financial sector—income through electronic platforms (electronic commerce, stock exchange), in the social sphere—various public services that are provided in electronic form; obtaining education using distance education technologies; in the cultural sphere—virtual exhibitions; in the legal sphere—public discussions of the submitted draft normative acts; use of electronic signature of documents. This list can be continued long enough.

At present, digitalization has an impact on public administration in various countries of the world [7]. For example, the French Council of State notes that digitalization has an impact on the state, and the adoption of decisions important to the state directly depends on the use of digital technologies in the process of their public discussion.

In the US state of Pennsylvania, the Child Protection Bureau uses an intelligent modeling technique to determine the solvency of child support payers to prevent them from breaking the law. The main result is the high level of child rights protection in Pennsylvania, which is recognized as one of the highest in the United States.

The German Federal Labor Agency conducts a continuous analysis of unemployment data based on a selection of different categories. As a result of this, not only budget savings are achieved, but also the time for finding a job for the unemployed is reduced. An important result is that the level of satisfaction with the quality of providing citizens with public services that are in electronic form has increased.

According to the authors of the Japanese concept of «Society 5.0», the development of the digital environment will lead to the fifth stage in the development of human society (the first four: primitive, agricultural, industrial and informational) [2].

Russian government is also actively transforming government into a digital environment. In February 2012, presidential candidate V. V. Putin turned to professional communities for help in order to create a friendly interface on the portals of public authorities, while considering the need to improve democratic institutions in Russia. «Such a contribution» will be highly appreciated by history, according to Putin [8].

In addition, V. V. Putin drew attention to the fact that citizens should be given the right to political participation and also participation of citizens in self-government and control. The main forms of such participation should include the opportunities, which have already implemented, for example, public discussion of bills, an assessment of the quality of their regulatory impact, monitoring of current legislation and the effectiveness of law enforcement practice.

The right to consider in the expert working groups the received public initiatives that have gained the established number of votes is essential.

It should be noted that public discussion of draft legal acts on the Internet harmoniously integrated into the system of public control in connection with the simplification of the procedure for the participation of civil society in this process.

The requirement of mandatory publication of draft legal acts on the official website and complete information on the process of preparation by federal authorities of draft legal acts and the results of their public discussion makes it possible for all citizens to quickly respond to upcoming legislative changes in important areas of public relations.

Digital technology is being introduced into the electoral environment.

Federal and regional laws have been adopted and they have enabled the implementation of electronic voting in the elections to the Moscow City Duma, which took place on September 8, 2019. Electronic voting was carried out in three constituencies along with the traditional method.

Thus, at present time, it can be argued that digitalization has the most direct impact on all aspects of public life, which leads to a significant change in existing values [9, 10].

A number of authors note that the idea of «mechanization» dates back to the Renaissance. It was then that humanity began to dream of an early replacement of a person with a car. This led to the conclusion of various kinds of contracts through machines in law. Subsequently, a process of gradual increase in the number of mechanical actions that were carried out without the participation of people began [11].

At present time, two diametrically opposite points of view are quite common in science. On the one hand, there is a position according to which the mechanization of modern law is impossible, at least as long as the existing human society is preserved on earth, in which people fully possess free will [12]. On the other hand, it should be noted that separate legal procedures can now be performed using electronic technologies.

For example, conducting a legal examination of draft legal acts in order to identify which of those have lost their relevance, or duplicate the rule of law, and, in addition, conflicts between them; anti-corruption expertise—to identify corruptogenic factors established by the methodology; drawing up statements of claim according to a certain algorithm embedded in the program. This is also confirmed by experts, for example, I. Kondrashov, who is the director of the legal department of Sberbank of Russia, indicates that systematic work is currently underway to exclude lawyers from all standard operations, which is solved through the robotization of individual legal processes [13].

In general, it should be recognized that legal practice is changing. Of course, it's difficult to assume that the legal process can be completely transformed into an electronic environment. This is due to many reasons, including the ambiguity of legal terminology (the simplest example is edged weapons), the need to evaluate evidence in a case, order not only a lawful and justified, and also a fair sentence by a court, etc., but certain procedures, of course. It's possible and necessary to robotize, this will facilitate the work of the lawyer and give him the opportunity to fully concentrate on the content of the process.

One of the most important aspects of the introduction of digital technologies in various spheres of the life of society and the state is the need to regulate these public relations by legal norms.

One of the first global international documents, which recognized that informatization will affect people's lifestyles and change the interaction of governments and civil society, was the G8 adopted in 2000 (heads of state and government) of the Okinawa Charter of the global information society.

Subsequently, issues of the information society (WSIS) were addressed at the Geneva stage of the World Summit in 2003. The result was the adoption of the Declaration of Principles on which the information society of the new millennium is currently being built. The main idea of this document was the expansion of cooperation in the information sphere, the development of the infrastructure of information and communication networks with the aim of their accessibility for all humanity.

At the Tunis phase of the WSIS, from November 16–18, 2005, close attention was paid to the need to protect personal data, to prevent misuse of information and telecommunication technologies for criminal purpose and also to expand their use for social purposes (for example, emergency warning etc.).

The decision, which was adopted by the Supreme Eurasian Economic Council: «On the main directions of the digital agenda of the Eurasian Economic Union until 2025» (October 12, 2017 No. 12), should be recognized as important international document in this area. It's noted that a possible economic effect with direct the implementation of digital technology is able to almost double the total gross domestic

product for member states. But, on the other hand, such challenges are indicated for all member states of the union, such as the release of significant labor resources, imbalances in all sectors of the economy and the depreciation of traditional assets.

In Russia, the need to regulate public relations in the field of digital technology development was noted in the Decree of the President of the Russian Federation «On the Strategy for the Development of the Information Society in the Russian Federation for 2017—2030» (dated May 9, 2017 No. 203).

President of Russia V. V. Putin annually pays close attention to the need to develop digitalization and the formation on this basis of competitive sectors of the Russian economy.

President of Russia V. V. Putin annually pays close attention to the need of developing digitalization and the formation on this basis of competitive sectors of the Russian economy.

For development of this legal act, the Presidium of the Council, which operates under the President of the Russian Federation, and which is responsible for strategic development and national projects, approved on December 24, 2018. Passport for the prepared program «Digital Economy of the Russian Federation» (planned to be implemented in the period from 2018 to 2024).

On May 28, 2019, in order to streamline the regulation of public relations in the field of development, use and development of digital technologies, the Federal project «Normative regulation of the digital environment» was adopted, which provides for progressive measures in this direction (protocol No. 9 of May 28, 2019).

Considering to the fact, that this direction of development is new, framework regulation seems optimal. It's along this path that the Russian authorities are following, which for objective reasons can't make an unambiguous decision regarding the procedure for regulating public relations in a specific digital environment. As a result, the Ministry of Economic Development of Russia has developed a draft law «On experimental legal regimes in the field of digital innovations in the Russian Federation», which covers such areas of state development as medicine, transport, finance, education, construction, industry, trade, public services, activities in the control and supervision sphere.

In this case, the state has taken the path of regulation through the creation of regulatory «sandboxes», the main advantage of which is the fact, that they allow a more flexible approach to regulatory requirements in order to ensure the development of innovations. Thus, authorities and also representatives of the business community involved in the development of new products and services, have the opportunity to test them without risk of violating applicable law, and subsequently, to enter the market with them, if the test was successful.

Thus, the conclusion suggests itself that digitalization, having penetrated into all spheres of the life of society, implies significant changes in the system of Russian and international law. It makes the formation of a new branch of law, digital law, quite realistic. At the same time, the development of digital technologies can generate significant discussion among legal lawyers.

This is due to the fact that digital technologies, first of all, provide one of the important needs of a modern person—the right to receive information. Digital technologies

provide unlimited opportunities for its receipt and processing, and therefore discussions about limiting or expanding the boundaries of freedom of individual rights will only intensify.

Digital technologies directly affect many fundamental human rights where a special place is occupied by the right to personal inviolability and privacy. They are recognized as basic, inalienable. Their social purpose is primarily expressed in the fact that these rights give a person a very important opportunity to satisfy their interests and also realize themselves as a person, using natural and social opportunities.

The main question is always how much a person, being in the digital space, has autonomy from other people. A person's freedom can't, by definition, be absolute in the context of the global digitalization of society, since any manifestation of it will can be received, recorded and transmitted to an indefinite number of people. In these conditions, absolute freedom will be identical to absolute lack of freedom, namely, the individual's unlimited dependence on the will of other people.

The vast majority of people haven't still realized how much autonomy on the one hand and dependence on the other hand gives people access to information. It becomes obvious that significant results can be achieved in the fight against corruption because of creating a new model of interaction between a person and a government representative. It's also important that the speed of dissemination of information increases critically, and its content doesn't always reflect reality. Government institutions are concerned about information dissemination processes and they are also trying to limit criticism of government institutions.

Based on the foregoing, we should agree with the proposal of V. D. Zorkin, Chairman of the Constitutional Court of the Russian Federation, which consists of substantiating the need for a constant search in the legislative regulation of an exclusively optimal compromise between the ability of state bodies to access information and the right of citizens to a confidential environment [14].

4 Conclusion

So, it should be noted that digitalization today represents a global phenomenon, as a result of which key areas of public life are changing. Law, which is a regulator of social relations, will continue to experience the impact of scientific and technological progress. At the present stage, with the development of mankind, there are no questions about choosing the way, since digitalization has firmly entered the life of everyone.

Changes are inevitable and ongoing processes, but digitalization can give it significant acceleration. Attention should be paid not only to the particular manifestations of the interaction of the digital space with law, but also to the systemic foundations of the theory of law. There are gaps in law and in the digital space, however, in legal science, ways have been worked out to bridge the gaps in law, and similar solutions

will be found in the digital space, including in the field of legal regulation of digital reality.

Alternative Models of Economic Actors' Behavior and Interactions Under the Digital Transformation

Elena V. Kulyasova, Olga T. Shipkova, and Nikolay S. Kulyasov

Abstract In the context of emergence of qualitatively new system of economic relations, the transformation of behavioral models and ways of interaction between the main participants of the triple helix model "enterprise/employer – university – state" involved in creation of innovations and development of society is considered in the article. New requirements to these subjects in the new VUCA-world are considered. Special attention is paid to the analysis of existing and prospective forms of cooperation between universities and business structures. The use of project-based learning is proposed, as well as the creation of a technological platform of digital meta-university as one of the sites for the development of innovative projects and training of highly qualified personnel.

1 Introduction

Subjects of modern economy have to exist in permanently transforming environment. Such transformation can be traced in the following context: changes in the values forming the business model; flexibility and openness to innovations; proactive position of all subjects in working with uncertainty; updated requirements for the functioning of systems (strength, versatility, flexibility, ability to evolve, compatibility). Thus, the changes taking place in the modern world at this stage of development of economic and social relations can be described by the following expression:

$$SPOD_{world} \rightarrow VUCA_{world}, \tag{1}$$

where $SPOD_{world}$ is a world of stability and sustainability, predictability, ordinariness and certainty, which has allowed plans and strategies to be developed and led to certain predictable outcomes. However, the changes taking place in the modern world, including the impact of active development of innovative and digital technologies, have marked the transition from one social formation to another. The components of the term $VUCA_{world}$ (volatility, uncertainty, complexity, ambiguity) have become an integral part of the decision-making environment of any economic entity. These changes are due to the digital transformation that has affected all aspects of economic and social life.

It is worth noting that the accumulation of new knowledge and skills will transform $VUCA_{world}$ into a new stable $SPOD_{world}$, which will lead to new changes and the formation of a new $VUCA_{world}$ [1]:

$$SPOD_{world1} \rightarrow VUCA_{world1} \rightarrow SPOD_{world2} \rightarrow VUCA_{world2} \rightarrow \ldots \rightarrow SPOD_{world\,n}$$

Each subsequent $VUCA_{world}$ has certain features of $SPOD_{world}$, and therefore the principles, strategies and other laws of $SPOD_{world}$ can be applied to the new $VUCA_{world}$, but for very limited and narrow conditions.

Thus, recent years have marked the transition to a new stage of social development, which M. Castells described at the end of the twentieth century in his scientific works "The Information Age: Economy, Society and Culture" in three volumes [2], where he considered and analyzed the changes taking place in economy, politics and culture from the point of view of formation of information society.

2 Background and Methodology

In today's economic environment, the most important factors capable of ensuring the development of socioeconomic, political and other spheres of Russian society, as well as a high level of competitiveness of the industrial sector and the country as a

whole, are information and communication technologies. The understanding of the significance of these technologies, as well as the need to stimulate the processes of informatization and digitalization, was reflected in the Presidential Decree No. 204 of 7 May 2018 "On the National Development Goals and Strategic Objectives of the Russian Federation for the Period until 2024", which defines "ensuring accelerated introduction of digital technologies in the economy and social sphere" as one of the national development goals of the Russian Federation [3].

Digitalization, as a new trend that has had an increasingly significant impact on the development of the economy and society in recent years, is gradually replacing the previously widespread automation and informatization processes.

In the context of the emergence of a qualitatively new system of economic relations, let us consider the transformation of behavioral models and ways of interaction, including the requirements for their sustainability, within the system "enterprise/employer – state – university", which are the main elements of the concept of the triple helix of H. Etzkowitz in stimulating the economy of knowledge, creating and developing innovations [4].

It should be noted that with the transition to the digital economy, the subjects of the business community, government and political structures, scientific organizations (universities, research institutes, etc.), as well as the processes, including the processes of management that take place between them now exist in the new VUCA-world, where new models of behavior, interaction between them, as well as effective management systems are only beginning to be formed anew. Thus, new conditions impose new requirements to all participants of economic and social relations and, accordingly, new principles of management of relations between them [5–7].

The business community needs flexibility and openness to innovation and digital technology. Moving to the fifth generation of innovation processes is a shift from closed to progressively open models with more blurred boundaries of the innovation organization. The new evolutionary stage is characterized by increased complexity and openness of the innovation process. Digitalization itself, despite its active development and the provision of a wide range of benefits to business entities, is now distrustful and carries significant barriers and risks among most businesses [8]:

- the complexity and high-tech nature of digital projects;
- high cost of implementing and adapting digital technologies;
- various types of cybersecurity threats;
- corporate structure rigidity and staff resistance;
- the extinction of certain professions, but at the same time the lack of skilled and highly qualified personnel;
- the need for a radical change in the business structure of the enterprise and a change in basic management principles;
- administrative and legislative barriers to the use of some digital technologies;
- the complexity of evaluating the effectiveness of digital projects.

Proactive attitude to work with uncertainty is required from employees of the organizations in the conditions of the digital transformation. An employee of the future is considered to be an object of a high degree of "anti-fragility", in Taleb's terminology

[9], i.e. a person capable of making decisions under conditions of "opaque environment" and contributing to the system's exit from the influence of variability and disorder with the best characteristics. In the context of an employer-employee relationship, controlling uncertainty does not mean destroying, reducing or silencing it, but rather implying the willingness of a specialist to accept challenges of uncertainty. In psychology, this is reflected in the concept of tolerance for uncertainty, which characterizes a person's resistance to conditions of uncertainty, variability, and contradictory information. This concept is related to the notion of risk readiness—as the ability to take conditions of uncertainty, the ability to make decisions and act in situations of incomplete awareness, lack of control over the situation [10]. Flexibility (elasticity), which ensures preservation of the system, and "anti-fragility", which contributes to its improvement, are the best response to unpredictable and/or unprecedented changes in the external environment, which is the field of decision-making for economic actors.

In addition, the workforce of the future must have a crosscompetent set of knowledge and skills to perform a wide range of tasks in the digital workplace and to manage digital processes, which places new demands on the future as a system for training future staff and retraining existing staff.

Under such conditions, a modern university cannot ignore the permanently transforming external environment and the requirements of internal customers. In order to successfully perform their functions in full, universities need to respond to the challenges of our time by establishing a system of sustainable interaction with the real sector, including potential employers. The task of universities is to provide their graduates with simple tools to work in the new environment and to meet the updated demands of employers. In order to ensure flexibility/"anti-fragility", it is necessary to design an educational environment that connects the elements of the "enterprise/employer – university – state" system and forms a deep professional knowledge while penetrating a wide range of related and other areas to achieve professional flexibility. It is necessary to build a system of sustainable interaction (ecosystem) with the real sector.

The task of the state, in the context of the increasing role of information and communication technologies in the socioeconomic development of the country, characterized by multifactorial impact on society, people, enterprises and organizations, is the need to develop mechanisms and tools to manage digitalization, both at the national level and at the level of individual economic activities and enterprises.

Figure 1 shows a diagram of the main tools for managing digitalization in different socio-economic systems. As can be seen from the figure, human capital is a key aspect in carrying out digital transformation at each level of management (enterprise, industry or government level).

Entering the era of digitalization, which fundamentally changes the structure of professions, poses new requirements to staff, changes operational processes and business processes in industrial enterprises, the state needs to be particularly active in supporting cooperation between higher education and enterprises. The interest in close cooperation between universities and business structures is increasingly evident not only to society and the state, but also to the enterprises themselves, which strive to

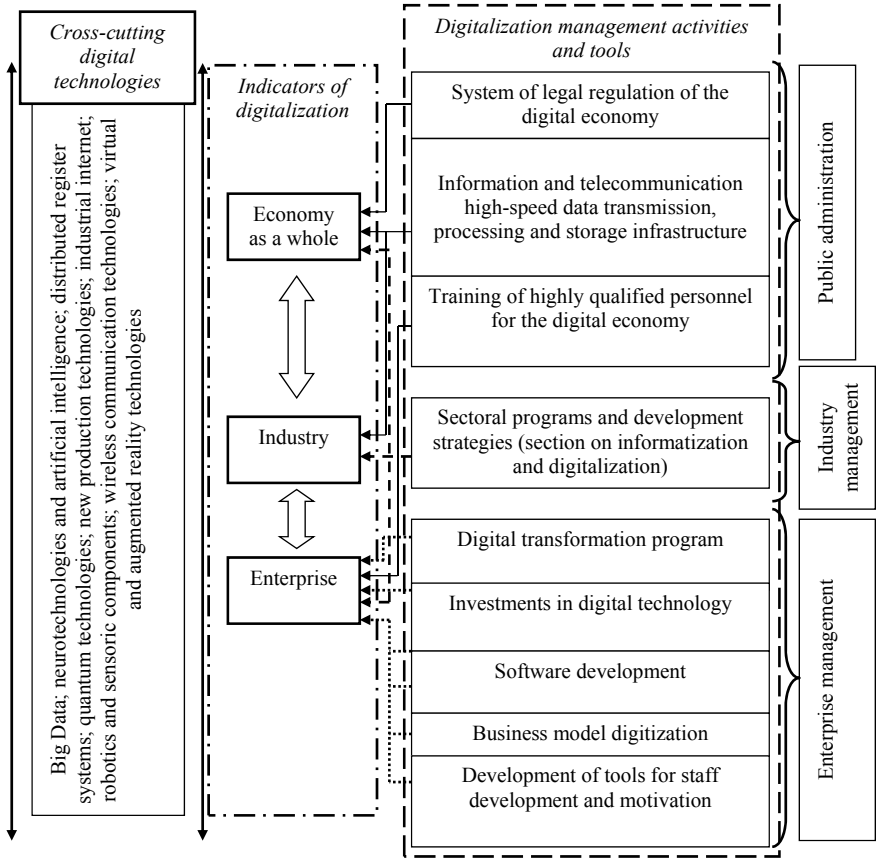

Fig. 1 Digitalization management activities and tools at various economic levels [11]

obtain highly qualified personnel to strengthen their competitive position and carry out digital transformation effectively. The need for cooperation between universities and business structures is also stressed in the "Declaration on Cooperation between Universities and Companies" adopted by the European Association of Universities to achieve the following positive aspects: increasing the relevance of education, the development of research and design activities and other forms of cooperation [12].

3 Discussion and Results

The problem of interaction between scientific organizations and industrial enterprises has been a long-standing one for Russia. Despite the obvious effectiveness and efficiency of this cooperation, which allows both sides to obtain positive results in the

framework of the implementation of the synergy effect, the existing barriers make such interaction unattractive, first of all, for industrial enterprises.

Let's consider the main groups of factors that prevent and limit the interaction of universities and business structures for the development of various forms of cooperation, both in the field of training qualified practice-oriented personnel, and in terms of development of research and design work.

Among internal factors related to the functioning of scientific organizations, the following barriers should be highlighted:

- insufficient level of qualification of researchers and teachers, not always corresponding to demands of the market and subjects of the commercial environment;
- rejection of the concept of consumer orientation;
- temporary aspects of cooperation;
- low quality of training of students/graduates;
- outdated material, technical and infrastructural base of universities;
- inertness and high level of bureaucracy in universities;
- functioning in isolation from the changes taking place in the economy;
- limited resources of universities to implement the tasks required for the necessary transformations.

The behavior of representatives of business structures also demonstrates a number of factors that hinder interaction with universities: the dubious profitability of joint projects, the orientation of commercial structures to short-term results, the investment process is perceived as initially high-risk, the lack of clear requests for a set of certain skills and competencies.

In addition to the above factors, it is worth noting that there are also the external factors which have a negative impact on the formation of a favorable environment for interaction between universities and business structures: the high level of risks in the Russian economy, the low level of development of the regulatory framework in the field of intellectual property, the presence of strict standards in education, the high level of control over the activities of universities, the slow response of the state to changes in the structure of demand in the labor market, the training and education of specialists in the necessary fields.

Despite the existing barriers, there are currently different forms of engagement that allow both sides to achieve certain goals. Figure 2 shows the main forms of cooperation between universities and business structures aimed at preparing new and improving approved educational programs, developing research activities, developing common areas of cooperation and supporting innovative business projects.

However, it should be emphasized that not all forms of interaction between universities and business structures are widespread. Thus, for example, according to the annual reports of the largest enterprises of the chemical industry, as well as the data of NIITEKHIM [13] it is necessary to highlight two main forms of cooperation between enterprises of the chemical complex and universities, the most common at the moment: the interaction within the framework of scientific research on the efficiency of operational and technological processes for the manufactured products

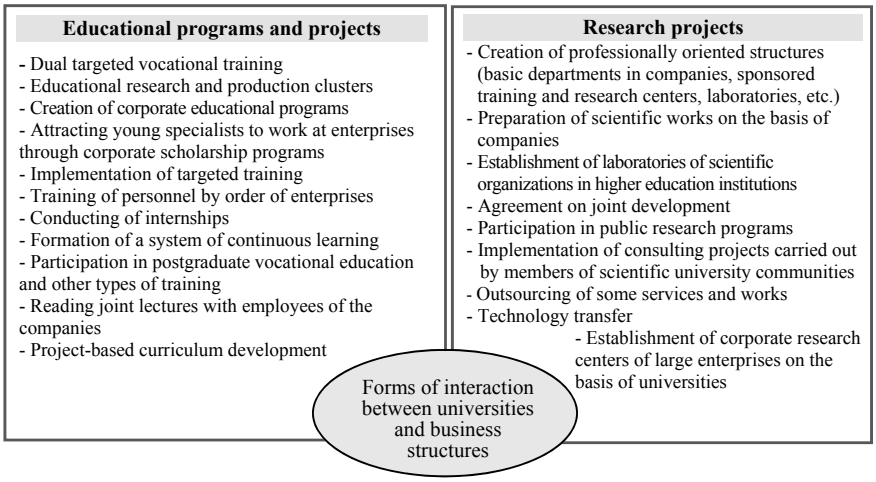

Fig. 2 Forms of interaction between universities and business structures

and development of new types of products, as well as the search for talented young people for further employment.

However, it should be taken into account that cooperation between higher education institutions and representatives of business structures, i.e. potential employers, must reduce the existing disproportion between the demand for higher education obtained by university graduates and the demand on the labor market. According to Rosstat data of 2018, the percentage of graduates pursuing the occupations for which they were qualified averaged 71%, while 29% had to work in other different spheres (Table 1).

It is also worth paying attention to the employers' dissatisfaction with the professional competence of the graduates: 91% mentioned the lack of practical skills and 53% said the level of theoretical knowledge was low. This trend is likely to be the reason for insufficient number of employed graduates in 2018—72%.

In our opinion, in modern conditions of development of digital economy it is expedient to offer actualization of transformation of approaches to training in university through the establishment of long-term sustainable interrelations with potential employers by joint project activity, including on the basis of system of national projects. Project activities within the framework of the educational process can

Table 1 Number of employed graduates pursuing the occupations for which they were qualified

Number of employed graduates in 2015-2017—total, thousand people	Including correspondence of profession		Percentage	
	Corresponds	Does not correspond	Corresponds	Does not correspond
2,447.0	1,733.5	713.5	71	29

become the basis for productive interaction between the education system and business community in order to achieve the common goal of training highly qualified personnel, which is in demand in the market.

Student projects for groups of students from real customers; diploma projects based on the requests of the industrial partner; individual courses organized by the university in cases when the industrial partner needs certain types of unique skills; jointly organized courses implemented by the university and the industrial partner around the central topics of common project activities—this is just the beginning of the list of possible types of interaction within the projects. However, it takes time and some work for the industrial partner and the university to find common ground. The task of the state is to quickly eliminate misunderstandings between these actors by actively involving them in national projects.

The concept of digital transformation of universities is also gaining momentum. In 2019, work began on the creation of the "Digital University" model as part of the Federal Project "Personnel for the Digital Economy" of the national "Digital Economy" project. This concept is aimed at the digital transformation of universities and includes four main blocks: online education, creation of special services, automation of infrastructure, creation of individual educational trajectories for students, that is, the introduction of the possibility of independent choice of a number of academic disciplines.

In Fig. 3 the model of the digital meta university allowing to unite in virtual space of a platform is presented: universities, corporations, research organizations, laboratories, the enterprises and development institutes for reception of the general access to

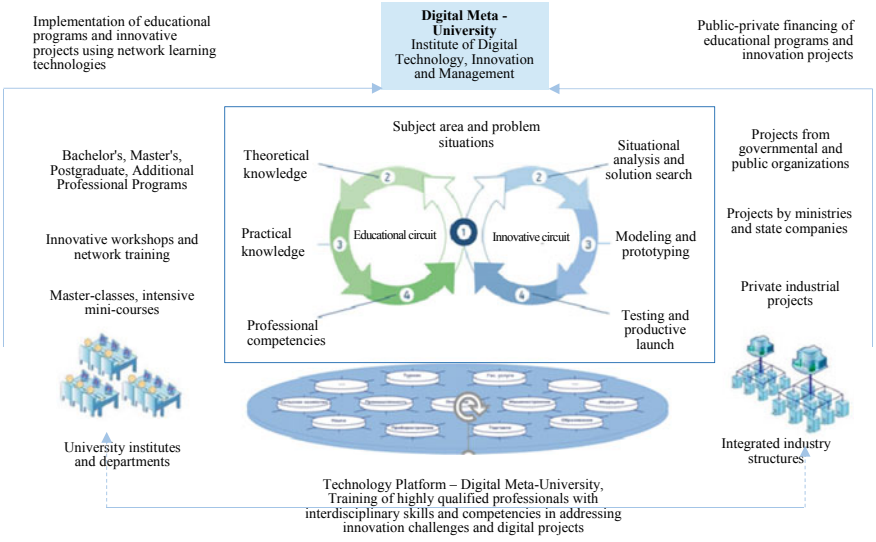

Fig. 3 Technological platform for the digital economy based on meta-university

information resources, possibility of realization of versatile training, and also performance of research and project works, the accelerated search of partners through the general database, and the main thing—increase of efficiency of interaction between all participants.

4 Conclusions

Thus, in the short term, as a response to the challenges of the digital economy and its new requirements to the main participants: "enterprises – universities – state" it is proposed to introduce a systematic joint project work covering the education system, the real sector and the state, in combination with classical education and digital opportunities of our time, based on already existing national projects.

In the long term, it is proposed to build an ecosystem (in Kleiner terminology [14]. Moreover, the basic links between subjects within an ecosystem are based not on the exchange of material and information flows, but on the transfer of rights of access to existential resources of space and time, in addition, access to the use of energy resources is important. The university ecosystem formed on the basis of project activities may become an element of a wider industrial ecosystem. Creation of networks of scientific and educational centers, participation of regional and municipal authorities as a customer, attraction of customers from large, small and medium businesses, etc. will allow such ecosystems to be oriented to the needs and requirements of regions and municipalities, taking into account the territorial differentiation of the country.

Impact of Digital Technologies on Management Economics of Russian Companies

Irina B. Rodina

Abstract The article analyzes the features and problems of management economics of Russian companies in the process of total digitalization. It is proved that the transformation of economic relations based on digital technologies, which cause a rapid multiple growth of data flows, speaks of the formation of a fundamentally new economy, when the relationship is dominated by the production, processing, storage, transmission and use of a huge array of digital data for economic analysis. Any company does not focus on the attribution of factors of production, but on the data about them and their applicability in everyday activities. The purpose of the article is to state the position according to which the introduction of breakthrough technologies in the business processes of the company provides not so much for the installation of modern equipment and software as fundamental changes in approaches to management, corporate culture, external communications, resulting in an increase in productivity of each employee and the formation of the image of a progressive and modern company.

1 Introduction

The increasing complexity and transformation of economic relations based on digital technology, which causes rapid multiplication of data flows, indicate the formation of a fundamentally new type of economy, where the relationship over the production, processing, storage, transmission and use of a huge array of digital data, which form the basis of economic analysis, is predominant. For any economic entity, it is not

E. G. Popkova et al. (eds.), *Socio-economic Systems: Paradigms for the Future*,
Studies in Systems, Decision and Control 314,
https://doi.org/10.1007/978-3-030-56433-9_28

the attribution of resources that comes to the fore, but data on them and their use in everyday business activities [1].

2 Background and Methodology

Digitalization opens up a wide range of opportunities for this organization in business cooperation with partners. Thanks to digital technologies, it is possible to develop entrepreneurship and find partners anywhere in the world, API makes such cooperation comfortable (for example, in the banking sector, software interfaces are used).

The author supports the position according to which digitalization means the introduction of breakthrough technologies in the business processes of the organization, implying not so much installation of modern equipment or software, but fundamental changes in approaches to management, corporate culture, external communications. This results in the growth of productivity of each employee, the acquisition of the image of a progressive and modern company [2].

In the context of this article, digitalization is considered not only at the microeconomic level, but also at the meso-level, when industries and regions develop in accordance with rapidly changing conditions, so that the digital transformation changes all subjects of the economic system. Thus, the digital economy is a modern type of management, characterized by the increasing role of digital data and methods of their management as a determining factor of production.

Technologies of digitalization give the chance to the organization to apply as much as possible personalized interaction by means of digital communication channels, omnichannel, artificial intelligence, use of robots [3]. For example, the digital transformation of banks involves chat bots, while the pharmaceutical industry is widely exploiting the capabilities of modern mobile devices. Digitalization optimizes the activities of employees while the productivity of each of them increases, as the automation of routine operations frees up time to solve complex problems.

If an organization does not take advantage of innovative technologies, does not adapt to the specifics of doing business in the digitalization process, it becomes uncompetitive [3].

Digital transformation of business processes is aimed at ensuring that the organization promptly makes decisions, adapts production activities and its management in accordance with modern requirements.

Digitalization allows to apply the following innovative methods of organization development:

(1) cloud technologies that allow multiple teams to simultaneously and efficiently use the resources of an organization within a single project;
(2) the Mobile First strategy, through which the organization receives and monetizes mobile traffic;

(3) off-the-shelf solutions that save time when applications, extensions, and connectors streamline the organization and require minimal time to implement and adapt.

These technologies have made the entrance threshold to many areas lower. Own business and its development have been simplified, thanks to fundamentally new tools that provide digitalization of industries and organizations.

3 Discussion and Results

It can be seen from foreign experience and Russian practice that digitalization has the greatest impact on banking, retail (e-commerce), transport, energy, telecommunications, education and healthcare. Digital technologies (Internet of Things, Big Data, use of mobile devices, ICCP, The Committee for Information, Computer and Communications Policy) have radically transformed social interaction and production relations, leading to institutional changes and the emergence of fundamentally new methods of cooperation and coordination of economic actors in joint activities.

It can be concluded that digital technologies are transforming socioeconomic systems. At the same time, the problems of developing the digital potential to achieve innovative growth of individual companies and industries have not been fully investigated, institutional aspects of the digital economy have not been studied, the problems of managerial economics in the conditions of digitalization have not been identified, and the role and place of digital economy in the system of production relations have not been determined [4].

According to the Organization for Economic Cooperation and Development (OECD), there is a global trend of steady annual growth in world trade in digital products (about 4%) and digital services (about 30%) [5]. Organizational research costs in the field of digital technology are growing faster than ever before. These circumstances indicate the growing importance of these technologies in the innovation of organizations. There is a trend of increasing availability of digital infrastructure due to 4G technology, fiber-optic data transmission, which contributes to a wide coverage of digital technologies [5].

At the same time, in the management economics of organizations there is an untapped potential for the application of digital technologies due to shortcomings in software and availability of qualified personnel. Since the technologies under research have a significant potential for accelerating innovation, investments in increasing the digital potential of the organization are a factor of its competitiveness. Modern business models and network structures radically change traditional business relationships and, consequently, imply fundamentally new management solutions.

Thus, the development of the digital economy affects the development of the Russian national economy. In view of these circumstances, the Russian Government pays particular attention to the development of the digital economy and its

advantages in addressing various macroeconomic issues (employment and unemployment, poverty and the environment). National digital strategies address problems of development of innovative organizations and functioning of the public sector in modern forms. A complex of measures of the state regulation promoting digitalization of national economy is offered: development and increase of safety of a digital infrastructure for occurrence of essentially new models of conducting national business; growth of level of mastering by breakthrough technologies through system of improvement of professional skill of the personnel; decrease in risks of digital economy.

If the digital economy is based on the application of breakthrough technologies and products, it includes: production of microchips, computer and telecommunication devices, electronic equipment; digital service organizations using digital means of production, storage and management of data. Large-scale programs to develop the digital economy in a number of countries demonstrate its growing importance to the national economy in terms of increasing national competitiveness in information technology, creating new jobs and increasing investment in digitalization.

The noted increased attention of states to problems of digital economy is explained by the fact that their presence negatively influences national competitiveness, leading to loss of competitive advantages. According to the theory of asymmetry of international trade, the digital lag of a country compared to the level of other countries inevitably leads to the lag of economic development of the country. Moreover, the peculiarity of this correlation is that it cannot be eliminated, since high-speed new digital technologies are reproduced on the basis of the results already achieved.

Hence, the state of the digital economy and its technological base is a condition for the development of national economy. It should be noted that the above-mentioned problem of the national economy can be solved by increasing import of digital goods and services. However, since the coefficient of renewal in the digital economy is significant, and the replacement of equipment and software is very fast, import substitution in this area contributes to the growth of competitive advantages of the national economy in the conditions of fierce competition for leadership in digital technology in the world [6].

Digitalization transforms existing production relations, creating previously unknown economic effects. The quantity of the models of behavior using the unreliable information or deforming the information about competitors and applied technologies is rapidly increasing. There is a growing criminalization of doing business, leading to economic losses for organizations that were not possible in the traditional economy. Economic theory should investigate the marked effects, interpret the existing terminology to the conditions of digitalization. The main components of the organization in the digitalization process are the use of databases, the use of information and communication systems in management. Transactions are expressed in data exchange and their interpretation that affect the interaction as a result of production relations, motivation, rules of behavior. In institutional economy the theory of the information with a method of the analysis of transactional expenses that allows to analyze industrial relations is synthesized.

Modern organization enters into complex interactions, which creates the need to aggregate them into a single management process, integrating the entire information environment into a single digital space. Under the information environment we will consider all software and technical means necessary for data processing, and also management of technological process of an organizational and administrative contour which should develop and implement concrete decisions in any area of activity of the organization.

Digital potential of the organization imprints on the level of its profitability, its transactional costs, efficiency, its possibilities in the market, i.e. it is much more important than the availability of the organization to raw materials, its financial position, etc. [3, p. 131].

Digital data is a resource that enables systematic planning of production activities in the long term. In the conditions of continuous improvement of data processing not only the ability to process rapidly growing volumes of information should be shown, but also the possibility of its application in production conditions with increasing returns on resource savings.

If in the twentieth century the basis of the world and national economies were oil and gas and other mining, machine-building, metallurgical companies, in the twenty-first century it is digital companies connected with production of electronics and information technologies (Apple), Internet service (Google), software (Microsoft), Internet commerce (Amazon, Walmart), telecommunications (China Mobile, Verizon, AT&T) [7] that are of great importance.

The role and place of exponential data sets for any socioeconomic system are so significant that this fact considerably transformed the economic theory, contributed to the formation of fundamentally new production relations. The following concepts were substantiated: the sixth technological paradigm (2030–2090) of Russian academicians Lvov and Glazev [1, 8]; information society of American economist Machhlup [9] and Japanese economists Umesao and Hayashi [10]. Without exception, all the theorists of the digital economy prove that economic processes are fundamentally changing, when the emphasis shifts from the production of material goods to the provision of digital services, increasing globalization, the main feature of which is the informatization.

The digital economy can be measured using the system of indicators proposed by the OECD [5] in such areas as: the share of the high-tech sector of the national economy in manufacturing, services and international trade; investment in research and development, software development, education, retraining; production of information and communications technology equipment; creation of new jobs in science and high technology; indicators of cooperation between organizations, venture firms, universities and research institutes; international knowledge flows, international cooperation in science and innovation; mobility of scientists, students; dynamics of Internet distribution. In analyzing the digital economy, the following criteria are singled out: changes in employment; geographical, technological and economic criteria [2, 11].

Since the emphasis in the national economy is shifting from the production of material goods to the production of digital services, social and labor relations are

significantly transformed by the fact that most of the economically active population works in the digital economy. Decrease in the share of employees in the real sector of the national economy and growth in the service sector indicate that physical labor is replaced by information labor. If the dominant factor of production is information (database), it means that the growth in the share of labor in the processing of information indicates a transition to the digital economy.

The analysis of the digital economy by geographical criterion consists in the fact that increased attention is paid to data transmission networks linking different regions, countries, and therefore these networks have an impact on the creation of the global economic space [12]. The most important factor is which aspect of data transmission to analyze. It is possible to analyze specific systems of data transmission in a particular territory or an array of data transmitted through networks, as well as the qualitative characteristics of the data. In modern conditions, the following issues are debatable: what should be considered as networks, what the differences between different networks are, what data sets and the speed of their transmission indicate a transition to a digital economy.

The technological criterion of the digital economy is related to the fact that the field of information and communication technologies is associated with innovative technologies that significantly change all production relations, which is supported by the capabilities of these technologies in modernization of the communication sphere, when fundamentally new services (e-mail, data transmission in the form of text, video files, social networks, messengers) appear.

The economic criterion of the digital economy implies that value in the production, transmission, processing and storage of information is taken into account. If such activities exceed those in the real sector of the national economy, this indicates the transition of the national economy to the digital economy, and data sets are the object of production relations, and therefore have value. The main problem is that the methods to evaluate the performance of the organization's data processing staff have not been developed. So, it is difficult to allocate a share of information-analytical department in organization production.

Many experts suggest measuring the digital economy by focusing only on the criterion of technology, which is controversial because digital technologies are numerous and constantly evolving, each of which has its own impact. It is difficult to find a single unit of measurement of technology, so it is difficult to determine the level of digital technology at which the national economy should be defined as digital.

Defenders of the concept of the primacy of technology over the formation of industrial relations say that in any historical period, breakthrough technologies first appear, then they already transform socioeconomic relations, separating the socioeconomic system and innovative technologies. It seems that breakthrough technologies always have a social patina and meet the demands of society. Therefore, it is a matter of discussion whether to emphasize technological criteria when analyzing the digital economy.

Many economists say that when a certain number of quantitative indicators are achieved, the national economy becomes digital, when quantitative changes (data

sets, number of employees working on data processing, number of telecommunication equipment, etc.) transform the qualitative characteristics of the national economy [12–16]. It should be kept in mind that repeatedly growing data flows are not so much a quantitative statistical characteristic but are considered as a homogeneous value [4]. When calculating GDP, qualitative indicators are not considered. However, data quality, data processing methods and management decisions are the most important circumstances in the digitalization process.

In our opinion, it is impossible to evaluate the quality of the digital economy based on quantitative characteristics, excluding the criteria of usefulness, when the main economic resource—the database—should be of high quality. A distinctive feature of constantly growing data sets is the difficulty in their structuring, use and management. In market economy there is information asymmetry of economic entities, reduction of public access database, growth of transaction costs, which are side effects of digitalization. Ways to accumulate large-scale data are enhanced by cloud storage, representing a system of hosted servers in the world, combined into a single virtual (cloud) server, where users place their data on a paid or free basis. In the cloud, files are stored like a computer hard drive, although they are not accessible from a single drive but from a variety of connected devices.

Breakthrough digitalization technologies [17] provide any organization with new opportunities to identify bottlenecks in production activities and find new ways of their development. Fundamentally new opportunities allow for innovation, which also leads to institutional changes, provided the prerequisites are met:

- new knowledge must be disseminated and multiplied;
- space needs to be created for spreading, multiplication and exchange of innovations.

Big Data technology significantly changes the level of economic management of the organization, giving the opportunity to obtain any information between any economic entities, to make macroeconomic, regional, industry and microeconomic forecasts, to automate the decision-making process, to build models of consumer choice, contributing to resource saving, optimization of wholesale trade, logistics, investment, reducing production costs.

However, a clear strategy is needed to transform any organization in a digital economy with a clear development goal and ways to achieve it. At the same time, it is necessary to be aware of the fact that the mentioned transformation is a long-term process, which implies a systematic approach, continuous development of the organization with the involvement of innovative advances. That is why the motives of the organization's management and its team are important, they need to define the purpose of the changes taking place, understand digitalization as a necessary requirement of time, bring this fact to the staff of the organization. The management of the organization should adapt not only its team, but also elaborate a set of measures to master new technologies by any member of the work community. The mentioned complex includes: various trainings, workshops, and retraining. The innovative technologies themselves can ensure adaptation of the organization. Thus, the possibilities

of UX design contribute to the fact that the software interface becomes more understandable; with the help of artificial intelligence, the organization can increase the speed of processing large data and making managerial decisions.

4 Conclusions

Several conclusions and summaries can be drawn.

Digitalization has a significant impact on the management economy of the company, transforming it, having a synergetic effect in creating a new business, the investment process, recruitment and retraining of staff, business partners, factors of production, consumers of finished products.

Since digital technologies radically modify public services, organizations have the opportunity to reduce production costs; the corruption component of business is significantly reduced, contributing to transparency. Consequently, these technologies promote the efficiency of government regulation in ensuring sustainable development.

In the conditions of digitalization, various risks arise in the management economics of a new generation organization, because against the background of companies that fully implement and use the advantages of breakthrough technologies, there are many enterprises (mainly regional) that are detached from global modern communications, thus, their activities are hampered by the creation of a national digital economic system [11, 12]. The differentiation of Russian organizations by the level of digitalization is not only about technology and human capital development, but also about institutional development.

The Russian Federation has a certain potential for the development of the digital economy, as its education system is well equipped to train the necessary personnel; Russian science and practice offer unique technological solutions, which contributes to the efficiency of digitalization infrastructure [18].

Project Management Transformation in the Digital Economy

Svetlana M. Sycheva, Tatyana F. Chernova, and Yuliya A. Evdokimova

Abstract In modern society, digital transformation is gaining pace and interest in project management in all areas of activity and across the world is growing annually. The Russian Federation is not an exception. The number of specialists in the field of project management is rising. This circumstance is fully justified because project management has proved its effectiveness in the world and has been recognized as a high-class organizational and intellectual culture of accomplishing various kinds of projects. The development of project management methodology in our century is contingent to a great extent on the state of the world economic system, science and technology, and new domains of knowledge. Nowadays, one of the key development trends of society as a whole is the digitalization of the economy. It affects shaping a new outlook of project management as a whole. The article explores the current trends of project management transformation in the digital economy that have primary importance for the sustainable economic development of Russia. This fact is confirmed by the adopted program "Digital Economy of the Russian Federation". Findings: 1. The peculiar effect of digital technologies on the project management has been revealed. 2. The vision of the project management advantages has been formed. 3. Various interpretations of the term "digital economy" have been studied and the author's definition has been given. 4. Examples of the impact of digital economy tools on project management have been found out and summarized.

1 Introduction

The growth of digital technology is changing the current economic system in all developed countries with traditional processes of production and consumption. Today, digital technologies create a new reality for governments, people, enterprises, organizations, global markets and promise a new flourishing path to any country [1].

Society has become more digital and connected with computers and algorithms that in some way mediate most of the people's daily activities. Digitalization is abstract and hard-to-understand, which makes thinking about the detachment of the digital environment [2].

In our opinion, project management has long earned recognition as one of the leading management concepts of today. Let's highlight that over the fifty years of development, project management has expanded the scope of its application and worked out the entirety of methods and tools for project managers.

The global trend of digital transformation makes to take a fresh look at the project management methodology. In our country there all the prerequisites and opportunities for unfolding the digital potential and stepping up the transformation of project management in the digital economy.

2 Methodolgy

This study has been conducted using the basic methods of economic science, logical description of the components and functions of digital technologies reflecting their essential properties, and integrated approach, that allows for the profound investigation of the scientific problem.

The methodological background of the study is composed of the general scientific principles of an integrated approach; analysis methods such as logical, factorial, comparative, strategic, managerial, economic and organizational-structural simulation, quantitative and qualitative research of the main trends in digital infrastructure.

Also, the fundamental concepts and provisions of domestic and foreign scientists in the field of management, system analysis, strategic management and planning, design of control systems formed the methodological basis of the study.

3 Findings

To date, new digital technologies dramatically affect the management, i.e. contribute to the emergence of new forms of communication between people, a higher standard of living, as well as the development of business in the country. Russia possesses the essential intellectual and scientific base, demonstrates unique solutions from the organizational and technological perspective, that allows for the establishment and development of an effective infrastructure of the digital economy in the country.

The entry into the era of the digital economy and forward movement towards digital transformation can be rightly considered the main stage in the evolution of project management. The development of the economy and its transformation when shifting to the next level (digital) induces to adapt available management approaches and tools [3].

In witness thereof, we can cite the words of Martin Sedlmeier (vice president of the International Project Management Association IPMA): "Digital transformation entails changes in project management" [4]. It is no accident that he entered computer technology in the five main trends in the development of project management.

However, in practice, there are discrepancies in the conceptual framework of the digital economy. Unambiguous definitions that could fully and clearly describe the essence of processes aren't available. Besides, there is no specific description of the impact of the digital economy on project management practices.

It was the desire to get to the root of the digital economy and to show its role in project management that inspired us to write this article.

Let's discover the essence of the term "digital economy", as well as its alternatives. For making a cut-off stand on this issue, first of all, we should familiarize ourselves with definitions formulated and presented in various expert sources. In this article, we will dwell on some of them.

Thus, in the opinion of I. V. Shevtsov, the digital economy is a well-established term, which is understood as an entirety of electronic goods and services manufactured by e-business and e-commerce [5].

K. A. Semyachkov means by the "digital economy" the modern type of economic management prevailed by data and its management methods as a defining resource in the field of production, distribution, exchange, and consumption [6].

V. V. Ivanov and G. G. Malinetskiy stress that the modern concept of the digital economy speaks about changing the technological pillar of the economy that will automate routine operations. This circumstance steps up the execution of many processes, opens up new opportunities, but does not touch the basics of the economy [7].

Other authors such as E. A. Nesterenko and A. S. Kozlova come to the conclusion that the digital economy is a system of economic, social, and cultural relations using digital information and communication technologies [8].

S. G. P'yankova finds out that the digital economy is up to provide high-quality ICT infrastructure and summon up ICT opportunities for the benefit of consumers, businesses, and the state [9].

Thus, having examined various interpretations of "digital economy", we can conclude that all definitions are similar, but are not comprehensive. In our opinion, the digital economy should be construed as a modern type of economic management where the people communicate in the virtual space through the technological infrastructure to gain benefits in material and information exchange, as well as to automate routine operations.

Within this topic, we will pay attention also to related terms "digitalization" and "digital transformation". As far as there is a single concept of the digital economy, these terms are regarded as alternatives. However, it is necessary to make a distinction between them. The digital economy is a result, while digitalization and digital transformation are only strategies of the digital economy through technical and methodological transformations.

Let's identify the advantages of the digital economy for project management methods and specify them.

From the perspective of project management, digitalization and digital transformation projects are not much different, apart from the scope. Digitalization is the automation of separate business processes, while digital transformation is a complex of digitalization projects converting customer's key business processes into digital form. Note that digital transformation in the sector of the real economy is a suite of projects to this date [10].

Unlike routine digitalization (automation), digital transformation, as a rule, is premised on some innovative business ideas and is delivered within a specific strategy. But no matter how viable the strategy, the company's ability to bring it to reality is crucial. Here it's possible to reckon upon long-standing project management methods.

Let us mark that the nature of project management is reflected in its subsystems. Subsystems can be called functional separation of key elements of project activities [11]. Some scientific schools of project management list about 14–15 subsystems of project management.

We will regard the most high-potential subsystems in terms of digital transformation. In that way, the primary subsystem is project content management. The content should be understood as an entirety of project goals, works, and fruits, as well as links between them [12].

Digitalization of the management operations in this subsystem allowed saving the time of setting goals and activities, automating their decomposition, representing the project in various structural models that facilitated the estimation of financial and material costs both for a suite of works and particular actions. The contribution of digitalization in multi-project companies carrying out several projects at the same time is invaluable. For example, using the potential of Big Data helps to take more right decisions in assessing the portfolios of real and potential projects, as well as gather valuable information both about customers or partners and competitors.

Utilization of blockchain technology as a distributed ledger in the management of company communications and projects allowed for recording and saving any information that should be made accessible to the public and protected from any editing or deleting. Digital identification without the transfer of personal information

will prevent any type of fraud, protecting the user from the unfair use of his personal data [13].

The next subsystem is the management of advertising and promotion of projects, as well as the running of advertising projects based on blockchain technology.

Here, the blockchain is capable of shaking the positions of intermediaries, so far as it gives direct control over the placement of ads and advertising costs. Still, the statistics on advertising campaigns can be rather easily tampered, but after the transition to blockchain this will be impossible

Breakthrough technologies raise the productivity and performance of the engineering company.

Thus, project management in the digital economy is foremost a software platform consisting of some programs that facilitate the automation of routine processes and the emergence of appropriate information space for intercommunication of stakeholders.

The main feature of digital transformation projects is in their potential to change the traditional business model for the model of multilateral markets.

To date, it should be made a distinction between projects on digital transformation. First of all, it is the need for a high-quality theoretical organization of the domain area and training of the project team before the launch of the project [10]. Next, special attention should be paid to the strategy and flexible approaches in planning, including the possibility of swift readjustment of the project under a three-stage scheme "as it is - as it should be - as it would be perfect". Also, with a view to understanding digital transformation as not only good programs, but also a proper business model canceling out the transaction costs for market participants, the solutions should be opened through interfaces and marketplaces as soon as possible. One should bear in mind that the digital economy is absolute and stiff globalization, therefore, digital transformation projects are continuously evaluated in relation to the level of international standards.

For example, with the development and promotion of the digital economy, the IT sector has grown rapidly, which affects the emergence of new software products and the upgrade of existing ones. They have become multi-purpose, more convenient for work, and easy-to-understand. Besides, it is worth noting the convenience of communications thanks to the abundance of instant messengers, social networks, and mailing services.

The transformation of project management in the digital economy is peculiar because in most situations they are related to the inculcation of information technologies. According to experts, it is hard to assess their fruitfulness, although thanks to digital transformation, projects are now developed and implemented faster than before.

It makes sense to pay due attention in digital transformation projects to risk management, including technological ones, with an account of the considerable innovative component. Also, the heed should be paid to recent flexible approaches, such as Kanban, Scrum, Agile, etc. [14]. In this vein, an effective and competent selection of skilled people for work on projects in a fast-changing environment comes to the

forefront. Alexander Tovb, President of the SOVNET Project Management Association, also took note of the growing popularity of IT and flexible methods: “Methods such as Agile arose in the field of developing applications. This is an important trend in project management. They can also be employed in the public sector, but in harmony with conventional methods.” In other words, he believes that the future lies in hybrid approaches combining flexible and conventional project management methods [15].

For example, specialized programs for the introduction of SCRUM in project management make the process more flexible and degree of control over resource efficiency higher.

New management tools will lower uncertainty, raise the flexibility and adaptability of projects to dynamic external and internal conditions. From then it follows that the organizations delivering the innovation development strategy should have software and hardware to execute the business process on project management. The digital economy sets new standards for project manager competencies. Managers of this competence will appear only when the company will change its corporate culture. Incentives for risk, building cross-functional teams, lifelong learning, exchange of experience, discussion of project ideas with top management, and cultivation of personal liability for the implementation of projects contribute to a highly innovative culture that encourages complex projects and motivates employees to take on new ambitious tasks.

A variety of techniques are suggested today for an evaluation of return on IT-investments. Among them area financial techniques, probabilistic methods, and qualitative analysis tools.

The merit of the financial method, as already specified, is in the application of criteria generally accepted in the financial sector and the availability of the required statistical base for calculations. The idea of probabilistic methods is to assess the probability of risk and the emergence of new opportunities (enhance the competitiveness of products and lower the risks of on-time project completion) using statistical and mathematical models. The essence of qualitative (heuristic) methods is in both quantitative and qualitative assessment of investment projects.

The main drawback of such methods is that their application requires the company to develop its scorecard and introduce it in all functional units along the entire added-value chain.

Thus, we can conclude that the methodical issues of assessment of digitalization performance have not yet resolved in domestic science and practice, which purports their further elaboration.

According to the above, we can enumerate the following advantages of the method making it demanded in almost any field:

- resource efficiency. Project management methods enable efficient management (allocation, redistribution, and optimization) of the main types of resources (terms, materials, contractors, funds).

- versatility. Project management has no functional constraints. Versatility consists in that the management of project-based activities can effectively achieve well-defined goals despite the variety of basic parameters.
- specification and preciseness. The main activity in the first stages of project management is setting goals, objectives, and works. Such a procedure allows detailing the entire range of works to be performed for the achievement of goals. Besides, thanks to the obtained knowledge, it is more convenient for companies to state both operational and strategic goals.
- focus on the implementation of specific tasks. Some companies need in the implementation of different (or specialized) in comparison with their principal activity. In such situations, the execution of intended tasks with design methods seems most effective.
- risk accounting system. One of the project management tools is a risk management system. Its advantages are an investigation of weaknesses (at the stage of project design), their classification, assessment, and development of smoothing measures.
- integral structure of methods and tools. Project management, like science, has existed and evolved for decades. Over the years, experts have developed, summarized, and proved various theoretical and practical tools and management methods. Such a system allows working on projects in an efficient and convenient way.

Thus, the transformation of project management in the digital economy should be a continuous process. This is the main idea since there can be no universal solutions for all sectors and companies.

4 Conclusions/Recommendations

Nowadays, there are various methods of project management. For instance, flexible project management techniques are most effective in the upgrade of systems, their adaptation, and the extension of functions. At the initial stage of implementation, it's advisable to follow the conventional approach, which sets strict deadlines for implementing and functional stuffing of the system. This allows the customer to fold the service on a particular day. We believe that one of the canons of the project management methodology is change management the observance of which will help to solve problems in the context of global-scale adjustments to requirements and goals of projects.

In project management software, there are both individual types of programs and convenient software packages that include all essential hardware for the provision of the main subsystems' operation and fruitful corporate communication between the project team members. Thanks to the above, the management process has become more convenient, efficient, and (what is more) faster. That's a particular achievement of the digital economy for the science of project management.

Modern Approaches to Digitalization of the Company's Financial Task

Anatoliy B. Yaroschuk, Anatoliy Grekov, and Makhmud-Khussein Orusbiev

Abstract The article discusses issues concerning the analysis and identification of modern approaches to the digitalization of the financial task of the company. Nowadays, digitalization as a phenomenon is changing the framework of the economy both for countries in general and companies in particular. Specifically, there has been a significant rise in competition between sectors, established world and regional markets have suffered changes, and the number of goods and services based on the latest sci-tech developments has augmented. The above evidences that "digitalization" is turning into a driver of both economic agents and national economies as a whole. Digital technologies and their property to transform a financial task through better planning and decision making, improved processes and efficient cost management are crucial for the resolution of current business problems. In this connection, the authors seek the main approaches to the digital transformation of the financial task, suggest measures to enhance the performance of the company's digitalization.

1 Introduction

Digitalization as a phenomenon is changing the framework of the economy both for countries in general and companies in particular. Latest sci-tech developments dramatically remodel the world and national markets, enhance intra-sector competition, thereby opening up virtually unlimited opportunities for the development of world commerce and the provision of services [8, 9].

The above and many other technological changes that have occurred in the real sector of the economy over the past decade demonstrate that digitalization is a critical and high-potential factor that contributes to the introduction of new technologies, the sophistication of existing technologies and development of new innovative solutions and business models [12].

Given that financial management plays an even more strategic role in providing the growth of company value through the management of expenses and risks, business strategy and revenue growth, the digitalization of the financial task is strategically important from the standpoint of well-timed and appropriate decision-making and its positive impact on the financial performance of companies [2].

The financial task is often constrained by slow and obsolete information systems and often localized solutions deployed without integration into a single digital infrastructure, which negatively affects the flexibility of the company in an unstable business environment. Digital technologies and their property to transform a financial task through better planning and decision making, improved processes and efficient cost management are crucial for the resolution of current business problems. However, digitalization cannot be started without the development and alignment of a digital transformation program as short, medium, and long-term plans mapped out with time prioritization of initiatives and understanding of the target state of the company.

2 Background Information and Methodology

Currently, the terms “digitalization” and “digital transformation” are quite common both in various news sources and development strategies of companies. It is worth noting that until recent times in the Russian Federation these terms have been defined ambiguously and have been used mainly by IT specialists and business analysts. However, in 2018 the State Duma of the Federal Assembly of the Russian Federation adopted the national program “Digital Economy of the Russian Federation”. The program is primarily aimed at an augmentation of domestic costs for the development of the digital economy, the establishment of stable and secure information and telecommunication infrastructure for high-speed transfer, processing and storage of data bulk that will accessible for all companies and households, prevailing use of domestic software by state authorities, local self-government bodies and companies [1]. In 2017, the digitalization entered a landmark stage. Every second inhabitant of the Earth has an Internet connection. According to the McKinsey Global Institute

[13] the next 20 years, up to half of all working operations in the world will be automated. In terms of scale and weight, this event can be compared with the industrial revolution of the eighteenth–nineteenth centuries.

Digitalization has enormous potential for transforming companies in different fields. For example, the annual return on the introduction of the Internet of Things by 2025 may amount to 4 to 11 trillion US dollars within a global economy [13]. With that, it should be borne in mind that companies that lead in this area will have unrivaled competitive advantages and will further cement their positions in the world, regional, and national markets.

The findings of modern research by international consulting companies [3, 4, 7, 11] exhibit the following:

1. The world's leading companies are already on the way to digital transformation. Along with that, many of them still have no comprehensive digitalization program. Existing pilot projects are implemented as a rule through stand-alone and often segmentary digital solutions.
2. The most popular digital solutions are robotics, chatbots, big data analysis, and machine learning.
3. The main qualitative changes expected from the digital transformation are higher productivity and lower costs.
4. Most companies that have started the digital transformation introduced a new position of top management—CDO (Chief Digital Officer).
5. The trend is the establishment of dedicated centers of expertise in digital technology. Their main purpose is to render various types of technological support to companies implementing digital technologies.

3 Discussion and Findings

Digital Economy: Key Features and Trends

While the term "automation" describes the transfer of some functions from a person to information systems, "digitalization" means the conversion of analog information or processes into a digital form for processing by information systems. From the standpoint of companies, the so-called "digital transformation" can be defined as changing a business model through the revision of current business processes and operations using digital technologies to raise financial performance.

Since the 1960s, digital innovation has spread throughout the world in a wave-like fashion from research centers of the USA, Europe, and the USSR. The first wave of digitalization automated the existing technologies, as well as the elaboration of various business processes in companies. The second wave (the mid-1990s) contributed to the diffusion of the Internet, mobile communications, social networks, as well as the advent of smartphones, which allowed consumers to aggressively use new technologies in their daily life. But this day many companies associate the term "digitalization" with the digitization of the operating model itself through the adoption of mentioned latest technologies such as big data analysis and machine learning,

AI (artificial intelligence) and robotics, the Internet of things and augmented reality [3].

To date the key technological trends from the perspective of the operating model in companies' use:

- Artificial intelligence (systems that can simulate human behavior as to decision-making based on collected information).
- Big data and predictive analytics (structured and unstructured data bulk that can be effectively processed with the help of the functions of statistical modeling, analysis of historical indicators, and planning for results).
- Blockchain is a decentralized data structure designed by certain rules and distinguished by non-alteration of already-existing records.
- Chatbots are computer programs operating inside the application and simulating text and speech to execute support functions, process requests, and search for information at the highest speed.
- Internet of things is a network of connected devices and sensors for collection and subsequent processing of information using big data analysis tools to improve the quality of decision-making.
- Optical recognition is a technology for the recognition and digitalization of workflow to speed up decision-making and customer servicing and automate accounting operations.
- Robotic automation of business processes is the programming of office processes to enhance operational efficiency due to the release of payroll funds and mitigation of operational risks.
- Virtual/Augmented Reality is an interface replacing visual, tactile, auditory, and motor sensations of the user with an interactive simulation, which allows reducing the process execution costs due to the design and simulation of work operations.

In addition to the modern technologies being introduced today, it worth highlighting the trendy tools that will be tested in 2–3 years:

- Digital twin is a digital entity reflecting a real object, process, or system.
- Edge computing is a technology consisting in the placement of data collection and analysis centers next to the data source to prevent the delayed transfer.
- Smart space is a physical or digital environment of people-technological systems interaction.
- Quantum hardware is a type of non-conventional computations based on the quantum state of subatomic particles representing information by elements designated as quantum bits or "qubits". [12]

The above-described technologies change the financial task of the company and immediately affect the quality component of operating activities.

Digital Transformation of the Financial Task of Companies

For the best results, the company should develop a digital strategy that is consistent with its digital framework. However, shifting towards the digital financial model is

impossible without a solid technological foundation. Digital transformation often starts with the collection, integration, easy access, and analysis of high-quality data. It should be noted that the cost of data storage, cloud infrastructure, and computing power has decreased by 100 times over the past decade.

This indicator is critical because digital data is based on predictive analytics, artificial intelligence, and other digital tools.

Collection of data and access to it can be expanded through the so-called "data lake", which is an essential part of the data and process architecture supporting the digital transformation. Unlike data warehouses that store and arrange only highly structured data, a data lake can accommodate almost any type of data in any form, from unstructured data and raw data flows into documents, emails, and audiovisual files. As a result, companies can move to a single data repository within the enterprise, which reduces storage volumes to a minimum and at the same time broaden the exchange of information and access to it.

As soon as auxiliary software architecture will be designed, the foundation will be laid for key digital tools such as predictive analytics, robotics, artificial intelligence, and machine learning.

Key approaches to the digital transformation of financial task embrace the following:

1. Automated planning and forecasting [5]

In today's unpredictable and swiftly changing business environment, plans and forecasts are short-lived. Digital tools can provide the flexibility and agility that are needed by management. Thanks to the automated budgeting, planning, and forecasting at the request, the financial unit can revise assumptions and input data and get instant feedback. For example, changes in tax policy or foreign currency valuation can be quickly and easily simulated and the budgeting period can be reduced to a week. Digital tools also make plans and forecasts more accurate, excluding human judgment and analytic errors. Using predictive analytics and algorithms, some analysts have raised accuracy by over 20% and cut forecast volatility by almost 50%.

2. Streamlined accounting and compliance with international reporting standards [6]

In making up financial statements for regulatory representation, accountants should collect and verify data in a highly-controlled environment to ensure accuracy and compliance of the statements as well as their audit which is an expensive and time-consuming process. Digital tools minimize discrepancies and increase transparency, thereby saving time. Automation of processes can even more enhance the control and efficiency of accounting and be extended to the entire accounting function, for example, taxes, payables, and receivables. The all-digital control system can even use algorithms to ensure data traceability and integrity and refine the management environment in general.

3. Making ultimate decisions

With access to higher-quality and latest data, financial experts can explore patterns and trends, gain new knowledge, and practice quicker response to market changes. Artificial intelligence, intelligent analytics, machine learning, and modern algorithms can identify unexpected factors that affect business performance.

4. Low costs and error reduction [10]

Digital tools are more efficient and less error-prone than humans. Robotic automation of processes can diminish the number of manual rule-based routines and dramatically reduce error frequency. As a result, 25% staff cuts are common in all routine financial tasks. Given that data and transactions are easier to verify, digital tools can lessen the need for outsourcers.

5. De-risking and higher profitability

Many financial tasks create economic value directly through treasury operations, such as funds and investment management, capital market financing, and currency exchange hedging. Machine learning and AI algorithms can provide impersonal predictive models that can help CFOs reveal and gain big financial advantages from these activities.

Digital technology can be the best solution to the problems of today's rapidly changing business environment. Relying on digital tools and their multiple advantages, CFOs can transform the financial task and add value to the business and at the same make out the balance between efficiency, effectiveness, and risk. The key point is to develop a comprehensive strategy to get the most out of digital tools.

4 Conclusion

Adopting the paradigm of the vital need for digital transformation, company management deal with quite obvious questions. What technologies should be necessarily implemented? In what digital solutions to invest under resource constraints? What impact they will have on operational performance? What is their payback period? How and on what horizon to measure the economic effect? How to move from a one-off pilot project to a large-scale digitalization program with its further approval in the company's strategy and manage the digital transformation? [12]. These questions do not have ready-made answers and companies know them as they accumulate their own experience.

As of today, the tasks and functions of modern companies change almost every day. Components such as mass digital literacy, the towardness to reasonable risk, an innovative approach to the resolution of current and emerging problems come to the forefront. Brand-new companies established on the basis of startups and innovative technologies will have significant advantages over traditional companies.

Along with that, companies that have been working in the company's market for a long time provided that they won't manage to duly implement digital technologies in their business can encounter very challenging and sometimes insurmountable problems. All of them urgently need to do their best and introduce modern digital technologies on the all-around basis to keep up with the time.

As far as digitalization persistently have a huge impact, companies make efforts to balance profitability with high-potential digital initiatives. For the management of the processes and expectations of both customers and investors, the financial unit of the company should skillfully manage widening digital opportunities. After all, only through integrated data and a full suite of digital tools, CFOs can discover and quickly respond to business changes in real time.

Creating and Measuring Company Value in the Digital Economy

Anna L. Denisova and Alexander N. Lopatnikov

Abstract The paradigm shift in the development of the global economy and the accent of Industry 4.0 raise interest in the digital transformation of companies. However, the methods of selecting the factors and metrics appropriate for analyzing and measuring the value it creates are yet to be developed. In this publication, we discuss the key factors that need to be analyzed and considered to improve the reliability of the measurement of the value created by companies and projects in the digital economy. Specifically, how the digital economy creates value and the related risks, the nature of competition at the times of digital monopolies, and what constitutes a digital business model. Additional research of the above factors will result in the development of new approaches to and methods of value measurement that take into account the feedback and network effects as well as externalities of the digital transformation.

Keywords Digital economy · Digital transformation · Business model · Value measurement

JEL Classification O10-O30

1 Introduction

The World Economic Forum (WEF) where the digital transformation of the economy has been widely discussed over the past few years called for a change of the management paradigm through the adoption of computers, Internet-based technologies and the use of artificial intelligence for management support and investment decision-making [1]. The significant benefits of the digital transformation in the industry and

E. G. Popkova et al. (eds.), *Socio-economic Systems: Paradigms for the Future*,
Studies in Systems, Decision and Control 314,
https://doi.org/10.1007/978-3-030-56433-9_31

its impact on economic development is becoming increasingly visible and acknowledged. The WEF estimated that more than 60% of the world's new GDP will come from digital products or services, with 70% of the new value will be created by digital platforms. The practical implementation of the innovations is noted to require significant investment, measured in trillions of dollars, which creates the risk of increasing disparity between countries since almost 50% of the world's population is currently not involved in the digital economy. The WEF concludes that "companies need to take a fresh look at creating, distributing, and sustaining value in this new environment." [2].

The economic changesof recent decades are often justifiably described using the adjective "digital" in various combinations, i.e., digital economy, digital technology, digital transformation, digital monopolies, digital professions, digital money, digital inequality, etc. The importance of digital transformation is evident, however, to understand and measure its impact on the economic development and the value it creates, the nounthat comes in combination with the adjective "digital" should have a priority of consideration. In both the analog or digital economy, the economy is the critical element. The excessive and not always appropriate use of the term "digital" often creates confusion and sometimes devalues its real significance.

Erik Brynjolfson, Program Director of the Digital Economy Initiative and Professor at MIT Sloan School, formulated the challenges for managing companies and the entire industries that the new economy creates:

> Gross domestic product (GDP) is one the most commonly used measures of economic activity. But GDP misses out on huge chunks of value in the digital economy. When digital goods, whether Google Maps or Wikipedia, are available free of charge, they make no impact on GDP despite the value to their users. Without a valid tool to measure the value of the digital economy, policymakers are left scratching their heads over how to manage it [3].

2 Materials and Methodology

Among the results of digitalization,there was a change in the structure of the economy and the type of companies that drive its development. It is well evidenced by the changes in the world's largest companies over the past ten years (see Table 1).

Today, seven out of the ten largest companies in the world by market capitalization are not only high-tech companies based on intangible assets—they are platforms. New formats of corporate economic activity and market organization raise a lot of questions for regulators and managers. Among other things, this is due to the notion that digital technology and the Internet can radically reduce costs, creating unique opportunities for consumers [4]. At the same time, the popular statement that the business model of platforms is practically devoid of costs requires significant clarifications. The fact that the end user of some digital services does not pay the full cost of the digital product or service purchased or received does not mean that the product or service of the transactional platform through which it is provided is free of charge. It means that the costs are paid by someone else, often the consumer themselves, but not in the form of a cash payment, but in the form of information provided

Table 1 10 Largest companies in the world by market capitalization, 2009–2019

World Top 10 as of 31 March 2009, billion dollars			
No.	Company	Industry	Capitalization
1	Kxxon Mobil	Oil and gas	337

9	Johnson and Johnson	Healthcare	372
10	Exxon Mobil	Oil and gas	342

about themselves. Often, the value of such information provided in exchange for non-monetary contributions is greater than the savings generated. In particular, because of the risks associated with its uncontrolled and unauthorized use. Increasingly, you can hear about the practice of successful monetization of data accumulated by social networks and transactional platforms in their own analytical applications or when selling accumulated data sets to other companies that are willing to pay a significant amount of money for it. Sometimes attempts to monetize digital assets end up in a public scandal, similar to the recent one involving Facebook and Cambridge Analytica [5]. The assumption that there is no 'free lunch' in the analogue economy is also true for the digital economy (Fig. 1).

The illusion of free services or digital goods (content) creates problems for regulators, company managers and investors who traditionally use prices as a measure of value creation and who need to be able to assess the value of data, a core component of digital goods and services [6]. The speed of digital technology development in this case is ahead of the speed of managerial and regulatory innovation.

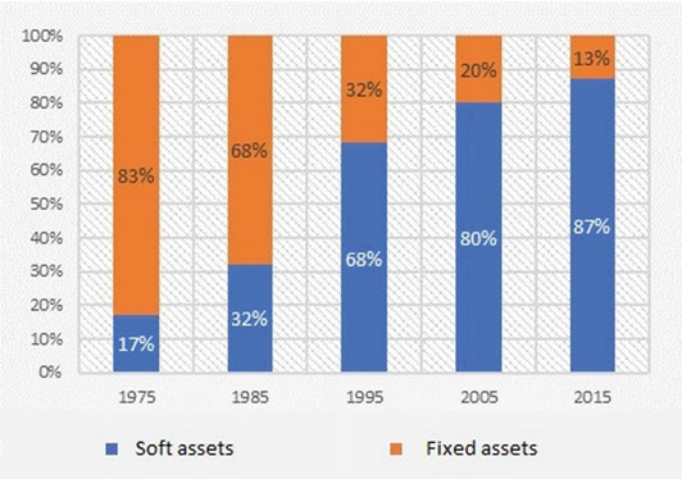

Fig. 1 Components of market value (S&P 500). *Source* Ocean Tomo's Intangible Asset Market Value Study

Economic development has always been accompanied by the evolution and transformation of the nature of competition of its subjects—from competition for access to raw materials (natural rent) to competition for goods and technologies (technological rent). As a consequence, over the last 40 years the economic balances (when assets are measured through market capitalization of companies) of the world's largest companies have changed radically. From the industrial companies, the main value of which was created by the capital invested in the fixed assets of the enterprises, the leadership passed to the companies, and the most valuable assets of the companies of the new economy were intangible assets, most of which, having a significant value, are not accounted for in the financial statements and balance sheets. An additional advantage of companies built on intangible assets is that their most important assets cannot be copied by competitors without violating international or national protection laws.

The current digital transformation of the economy is largely due to attempts to create additional value by developing a new class of intangible assets—digital assets. The novelty of this category of assets leads to confusion as to their definition and distinction from a wider class of intangible assets. As a result, you can see unexpected estimates of the value of the main asset of platform companies, where such an asset is called the brand of the company—a marketing asset, not a technological one. An example of such an estimate [7] is given in Table 2. Without denying the significance of brands created by the world's largest technological companies, it is difficult to believe that it is a brand that can account for up to a third of their value measured through market capitalization. It might be a reflection of an incorrect taxonomy of intangible assets and a reason to clarify it.

Table 2 The world's most valuable brands 2019

• Amazon $315.5 billion
• Apple $309.5 billion
• Google $309 billion
• Microsoft $251.2 billion
• Visa $177.9 billion
• Facebook $159 billion
• Alibaba $131.2 billion
• Tencent $130.9 billion
• McDonald's $130.4 billion
• AT&T $108.4 billion

Equally important and urgent is the task of accounting for new digital assets in the financial statements of enterprises. Unfortunately, the issue of recording in the financial statements of intangible assets created in the course of companies' activities is still unresolved [8]. Based on this, it can be assumed that the assets created in the process of digital transformation will be visible only in the market capitalization of companies for a long time and will remain out of sight of managers of the companies themselves, their investors and regulators. Without being measured, they are unlikely to be subject to management or taxation. The importance of fair taxation of intangible assets and intellectual property, especially in cross-border transfer transactions, is growing, and addressing it is a priority for OECD and national regulators. [9]. It can be assumed that it will become even sharper as transnational digital platforms continue to develop.

A distinctive feature of competition in the digital economy, one of the forms of evolutionary development of the knowledge economy, has become competition based on the advantages associated with the quantity and quality of data, as well as algorithms for their processing, analysis and use for making various operational and investment decisions. The next phase to which we are only approaching today is competition through the use of artificial intelligence [10]. The expected economic effect of AI technology development will certainly be significant, but it must be recognized that there is still no reliable tool to measure the value it creates. Moreover, it became clear that the next and much more significant step in the evolution of competition will be the competition of artificial intelligence among themselves. One can only hope that the economic consequences of this change will be taken into account and assessed in advance.

Today in the world not only the majority of the largest companies are platforms, but also among new companies, the so-called unicorns, about 60–70% are transaction platforms. Among the examples of what factors bring success and create value for transactional platforms, a new type of infrastructure company providing e-commerce, can be mentioned:

- open-mindedness;

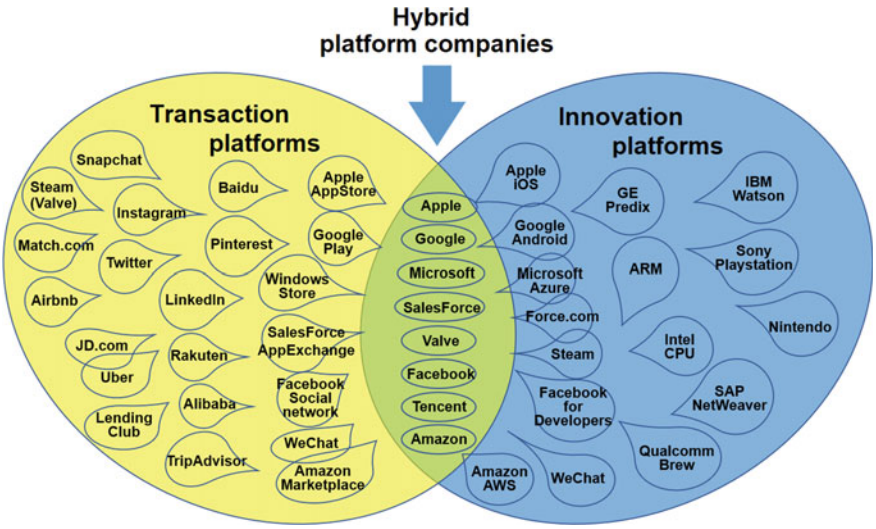

Fig. 2 Types of platform companies [12]

- ease of access;
- modularity;
- scalability;
- size;
- activity.

At the same time, the operating models of platforms are constantly evolving. The most successful of them have a so-called hybrid structure (such as Apple, Google, Microsoft and others) [11], combining (a) the benefits of a single ecosystem that they have created to integrate technological innovations, and (b) the benefits of maintaining an active transactional infrastructure of the direct exchange intermediary and beneficiary of the emerging network effects (Fig. 2).

Important, if not critical to understanding and analyzing the value created by platforms, is the asymmetry of benefits, where the winner gets everything. This factor has an aspect already recognized as negative—an unprecedented level of monopolization in the platform market. A vivid example of the dominant role of digital technology market leaders is the fact that after Google left the Chinese market in 2010, its Chinese competitor Baidu was able to collect 70% of the revenue of the entire search segment in the country. Another company —Alibaba—earns an extremely high share, almost 80% of all e-commerce revenue in China. With over 800 million active users of WeChat and QQ services, another Chinese IT giant, Tencent, serves approximately 60% of the country's population (Table 3).

It is useful to remember that the capitalization and revenues of major technological companies are comparable to the budgets and the gross domestic product of quite large countries. At the same time, it is difficult to foresee how the development of

Table 3 Market capitalization of the world's largest platform companies as of December 2019, million US dollars

Amazon	883
Facebook	569
Alibaba	525
Tencent	403
Visa	392

the market can change the existing "digital divide" and how antitrust practice of the early twentieth century is applicable in this case. The asymmetry of the emerging market is illustrated by the analysis of the so-called unicorn companies, i.e. those new technological companies whose expected market capitalization exceeds one billion US dollars. China has recently become a leader in the number of such companies. However, even the total capitalization of Chinese unicorn companies, estimated at about $400 billion, or about 36% of all such companies in the world [12], does not compare in any way to the "trillionaires" leading global platform companies. The cost of China's 15 largest unicorn companies in the field of artificial intelligence is estimated at about $40 billion, which is almost imperceptible against the background of the capitalization of technology market leaders, including China itself. Many new successful companies at a certain stage of their development are likely to be taken over by some of the largest monopolist companies, further increasing their value and distance from other market participants [13].

The challenge of the transition to a digital economy is not only the urgent need to regulate the sector, whose importance, size and level of monopolization are rapidly increasing, but also the fact that the return on capital is steadily higher than the return on labor [14]. The increasing share of capital invested in assets with high and growing levels of automation and digitalization only reinforces this imbalance. For today's society, where consumption is the main factor of economic growth, such dynamics cannot be considered a factor of sustainable development [15].

Difficulties in determining and measuring the value of digital assets are complemented by the appearance of digital means of calculation—cryptocurrencies. Confusion is caused by attempts of active supporters of digital money to define it as a new "digital asset" that has not only a price—formed in the supply and demand market—but also a fundamental value that money that is not secured by state obligations does not possess. Even the pejorative phraseology used to describe devalued money, which is said to be "not even worth the paper on which it is printed", does not apply to them—cryptocurrencies have no physical essence. The view of the clear majority of economists was formulated by Aswath Damodaran, Professor at New York University, who stressed that it is fundamentally impossible to determine the cost of bitcoin or other cryptocurrencies, you can only find out the value in transactions with them [16]. This, however, does not stop supporters of the view that cryptocurrencies are a

new kind of asset that continue to invent ways to "calculate" their value. The problem is partly alleviated by the low level of monetization of the financial sector with digital currencies, but it does not eliminate the terminology itself and the risks associated with it.

Another digital innovation in finance, asset tokenization, is equally questionable. Defined as "the process of converting rights or ownership interests in an asset into a digital token in a Blockchain system" [17], tokenization is declared to be a revolutionary way of creating liquidity for a wide range of traditionally illiquid assets, including by, as financial innovators claim, "increasing the transparency and reliability of data" about such assets.

What is to be tokenized? Practically everything that today is not the object of transactions on regulated stock exchanges and therefore has no reliable market price reference: financial instruments, real estate, precious metals, intangible assets—copyrights and intellectual property, rare cars, works of art.

It should be noted that both the problem of digital currencies and the problem of asset tokenization are primarily of a legal nature, related to the understanding of the nature of the rights associated with them and the methods of their regulation. From an economic point of view, tokenization is essentially an attempt to create parallel and yet unregulated markets for illiquid assets rather than new markets for them. The existing practice is not enough to predict whether this financial and technological innovation will lead to a clarification of the value of illiquid assets and reduce transaction costs or create problems similar to those of building financial pyramids. It is important to remember that corporate finance has not yet created a reliable tool for assessing partial and even more digital rights to analogue assets. At the same time, the estimation of the value of partial rights, illiquid and high-risk assets remains an unexplored issue, while the error of measuring their value is significant and fundamentally unrecoverable.

An immanently unrecoverable error in measuring the value of high-risk assets determines the specific type of investors in venture projects and the portfolio approach to investment they use. Let it also not be forgotten that these are first of all experienced qualified investors, public offerings of shares of such companies take place on specialized platforms, with a special procedure of regulation and admission to them of both investors and issuers. The emergence of an uncontrolled market for digital assets and the attraction of unsophisticated investors can create problems more significant than the infamous ENRON, Bre-X or Madoff pyramid.

3 Results and Discussion

Among the features of new technologies, new corporate and market structures that make it difficult to determine the value they create are the high speed of change, the novelty of the technologies themselves, as well as the presence of complex feedback, network effects and externalities. Absence of methods for analyzing the value of companies in the phase of exponential growth expectations and at the same time often

deprived of not only profit but also revenue, lack of analogues and reliable history—all this leads to distortion of managers, investors and regulators' perception of the real potential of such companies. And the indirect financial or operational metrics they use are illustrations of expectations rather than indicators from which the value of the investment can be determined. The problem is not new, well known since tulip mania and subsequent crises, including the relatively recent but almost forgotten dot.com crisis in the early 2000s technology companies market.

The demand for new digital business models that is taking shape today means that virtually all companies want to see themselves or are trying to present themselves as digital while remaining essentially analogue. The history of WeWork and its investor SoftBank is a clear illustration of the dangers associated with misunderstanding of new organizational forms [18]. A company that tried to implement a number of innovations in the real estate market, but did not become digital, determined its value using the metrics of digital companies. The result was a mismatch of valuation with market realities, a multiple reduction in this valuation within just one year, a multi-billion-dollar loss of an investor and the resignation of the company's manager and chief ideologist [19].

The economics of the platform business model is an emerging field of knowledge. Standard metrics—such as market share and savings on operating costs—may not be applicable to value analysis of platforms that are supported solely by fixed and significant capital infusions, as in the case of Uber [20]. The shareholders of such companies, sometimes unaware of it, actually pay for expensive experiments to study the economic model of growth without creating value.

Perhaps the most difficult event for economic analysis of digital companies is the emergence of a new class of technology based on the use of artificial intelligence systems. With the unquestionable attractiveness and significant potential that the use of such technologies has, the issue of the risk they pose to individual users and to markets in general has not been fully explored to date. In many cases, neither the size of the risk nor the price of a negative outcome are known, as in the case of autonomous AI-based systems without human involvement. Existing financial models for value determination based on income and risk indicators are not applicable to projects whose risks cannot be defined and the amount of damage in case of a negative outcome can be catastrophic. All this leads to high uncertainty of estimates of the cost of similar projects and companies, many of which are built on the proportion of the size of investments at the intermediate stages of the project's financing and clearly cannot be considered as any reliable indicators of their value.

The solution, which follows from the above analysis, should be the advanced development of methods and tools of value analysis, created in the process of digital transformation of the enterprise and the economy as a whole.

4 Conclusion

This publication considers the factors requiring detailed analysis to improve the reliability of the measurement of value created by companies and projects in the digital economy. These include nature of value and risks in the digital economy, peculiarities of competition at the time of digital monopolies, and defining the digital business model.

A more in-depth study of the above factors will make it possible to create new approaches and methods of cost calculation that take into account feedback, network effects and externalities of digital transformations.

Information Analytical Support of Analysis of Digital Economy Development

Marina D. Khabib, Marina Y. Teplyakova, and Aigul K. Bekkhozhaeva

Abstract The modern stage in the development of society is characterized by the practical introduction of digital technologies in many areas of life. The aim of the article is to research information and analytical support for the analysis of digital economy development both in the Russian Federation and abroad. The article reveals methodological approaches of international organizations in forming a system of indicators. Results: 1. The chronology of development and implementation of the main regulatory documents, on the basis of which data are collected by countries and compared, is considered. 2. An analysis of Russia's place in ratings compiled by various international organizations is presented. 3. The system of indicators of the national system of monitoring of development of digital economy reflecting factors of development of information society and use of information and communication technologies (ICT) is presented. 4. The index of ICT development in the regional context for 2014–2018 was calculated and analyzed in dynamics.

1 Introduction

The development of digital technologies at the present stage has entailed significant changes in the structure of economies of many countries. A new sector of information and communication technologies has appeared, the level of development of which determines the degree of penetration of digital technologies in most spheres of public life and sets the vector of technological development of our state economy. Thus, the problem of obtaining objective data reflecting the characteristics of the information society development becomes urgent.

Currently, the demand for data on the development of the digital economy in different countries has increased significantly at the international level, making it necessary to improve the existing information support system and adapt it to the changed conditions [1]. In recent years, existing standards for statistical monitoring have been revised in terms of the expansion of surveillance facilities and the number of indicators reflecting the use of digital and information and communications technology (ICT).

2 Background and Methodology

The need to observe and collect data on the development of the information society was first raised by the UNESCO Institute for Statistics [2] in the early 2000s. Taking into account the importance of the issue, the United Nations held a number of international forums, which resulted in the adoption of a "Declaration of Principles" and "Action Plan" reflecting the nature of interaction among all stakeholders. In addition, approximate indicators for the application of ICTs in selected countries have been identified.

The observing system for ICT applications, building the information society and the digital economy depends on the availability of reliable data on key indicators [3]. The list of relevant ICT indicators was developed by the Partnership on Measuring ICT for Development and endorsed at the thirty-eighth session of the United Nations Statistical Commission in 2007. In subsequent years, it has been updated to reflect emerging needs for additional data [4].

Currently, country data are collected and compared in accordance with the recommendations of the following documents presented in Table 1.

These Guidelines recommend integrated indicators calculated using the index method of analysis. Among them we can highlight: Network Readiness Index (WEF, WB and INSEAD International Business School, since 2002), E-Government Development Index (United Nations Economic and Social Development Department, since 2003), National Competitiveness Index (WEF, since 2004), ICT Development Index (ITU, since 2007), World Digital Competitiveness Index (International Institute for Management Development, since 2017), Global Cybersecurity Index (ITU, since 2017), etc.

Table 1 List of documents regulating research on digital economy development

The digital economy and society index)	Eurostat, 2016
Methodological manual for statistics on the information society	Eurostat, 2004, 2009, 2019

In the Russian Federation, information obtained on the basis of federal statistical observations, special sampling observations and special expert and population surveys is used for monitoring the development of the information society [5]. Th leading role of federal statistical observations should be noted, which form the information infrastructure of research aimed at obtaining objective and comprehensive data from all possible sources that meet the requirements of data reliability, compliance with current methodology and international standards.

The system of indicators for "monitoring the development of the information society in the Russian Federation", applied in modern statistical practice, allows obtaining data on the business sector, public administration sector, social sphere, households and population. The main role in monitoring is assigned to the Federal State Statistics Service, which coordinates the activities of ministries and agencies.

Monitoring of information society development in Russia at the national level is carried out in the following areas [6]: factors of development of the information society; use of information and communication technologies for development. Each of the above directions is represented by groups of indicators reflecting the development of the information society. In particular, there are two main subgroups in the group "Information Society Development Factors", which include the following indicators: ICT—infrastructure and access, Information Industry, Innovation Potential, Human Capital, Economic Environment, Information Security.

In order to study the current state and dynamics of development of the level of informatization in the constituent entities of the Russian Federation, monitoring has been conducted since 2017 on a system of indicators based on the "Methodology for assessing the level of development of the information society in the constituent entities of the Russian Federation" [7]. According to this Methodology, it is possible

to obtain data not only on the level of development of the information society of regions in all spheres of activity, but also to build a generalized ranking of regions by the level of information development. Ratings allow to rank the constituent entities of the Russian Federation by the level of informatization and to identify leading and lagging regions in this area, to assess the degree of their information inequality, and to make necessary and effective managerial decisions to eliminate this inequality.

Determination of the rating of information development of individual subjects of the Russian Federation is carried out according to the Integral index of Information Society Development. In its development, international experience in building composite indexes in the field of information development [8] was taken into account, as well as methodologies for building the following international indexes: ICT Development Index; E-Government Development Index; Network Society Readiness Index.

The Integrated Information Society Development Index in the constituent entities of the Russian Federation has a two-level structure. It is composed of two index-components: "Information Society Development Factors" and "ICT for Development". Each of the index-components includes a number of sub-indexes. The first index-component consists of four sub-indixes, while the second one consists of fifteen sub-indexes.

It should be noted that the weight of the index component "Information Society Development Factors" is 1/3 in the value of the Integrated index of information society development, and the component "ICT for Development" accounts for 2/3 of the weight in the value of the index. The weight of the sub-indexes in the value of the index-components is distributed in proportion to the number of their components.

When calculating the Integrated Information Society Development Index in the constituent entities of the Russian Federation, normalized values of indicators are used. The normalized value of the index is determined in accordance with the method of normalization of values used in the calculation of the ICT Development Index (IDI), i.e. the ratio of the actual value to its reference value.

The calculation of the Integrated Information Society Development Index includes a rather large range of indicators (more than 100 indicators), and in order to improve the reliability and relevance of primary information, the Russian Ministry of Communications has developed an automated information system "Electronic Region" (e.g. Automated information system "Electronic Region") [9]. Owing to the introduction of this system the procedure of data collection and processing for calculation of the Integrated Information Society Development Index of subjects of the Russian Federation and construction on its values of regional monitoring of level of informatization has been fully automated.

Only federal and regional executive bodies have full access to this system. At the same time, four items are publicly available: top 5 regions in terms of ICT budgets (for the last two reporting years), the structure of the regions' costs in terms of the three main directions of ICT implementation, the sectoral structure of the regions' costs of IT budgets (for the last three reporting years), top 5 regions in terms of growth of costs on ICT (for the last two reporting years).

In order to study the level of informatization of the Russian regions, the authors calculated and analyzed the structural components of the index of ICT development in the context of the Russian regions for the period 2014–2018.

This index can be considered as a system comprising three sub-indexes. In particular, the following sub-indexes are highlighted: access to ICT, use of ICT and ICT skills. The presented system of indicators consists of weights and their distribution according to the 2007 methodology (Table 2).

Of the 11 indicators presented, official regional statistics do not include three indicators that are part of the ICT Skills Sub-index. They have therefore been replaced by indicators that are sufficiently close in content. In particular, indicators have been introduced to reflect the literacy rate of the population, the share of students enrolled in higher education programs in the total population, and the share of students enrolled in specialized secondary education programs in the total population. These indicators are used to calculate the Human Capital Sub-index in the Integrated Information Society Development Index.

With a view to creating an information base for research into the development of the digital economy and the practical solution of issues arising in this regard, the

Table 2 ICT development index indicator system

	Indicator weight	Sub-index weight
ICT access subindex		0.4
1. Number of mobile cellular subscribers per 100 inhabitants	0.2	
2. Share of households with access to the Internet in the total number of households	0.2	
3. Share of households with a personal computer in the total number of households	0.2	
4. The number of fixed-line telephones per 100 inhabitants	0.2	
5. Internet bandwidth per user	0.2	
ICT usage subindex		0.4
6. Share of the population—Internet users in the total population	0.33	
7. Number of subscribers to fixed broadband Internet access per 100 population members	0.33	
8. Number of mobile broadband Internet subscribers per 100 inhabitants	0.33	
ICT skills subindex		0.2
9. Average duration of study	0.33	
10. Gross secondary school enrolment	0.33	
11. Gross tertiary education enrolment	0.33	

information and communication technology sector has been identified in the statistical data system: telecommunications activities; information technology industry; other information services; ICT production; wholesale of ICT-related goods.

To get an idea of the characteristics of ICT sector indicators at the macroeconomic level, we have calculated the values of the following indicators: investment in % to GVA, GVA per employee and investment per employee.

3 Discussion and Results

Russia's positions on a number of international indexes (Higher School of Economics [10, 11]) look as follows: by the ICT Development Index, according to the data for 2017, Russia ranked 45th with the value of 7.07 against 42nd place and the index value of 6.79 in 2015, and the first place was steadily held by Iceland with the value of 8.98; in 2015, the index value was 8.66; by the E-Government Development Index in 2018 Russia was ranked 32nd with the Index value of 0.7969; in 2016 it held 35th place with a value of 0.722, the first place in 2018 was held by Denmark with a value of 0.915, in 2016 by the UK—0.919; in 2017 for the Global Cybersecurity Index Russia ranked 10th with a value of 0.788, and in 2018 with a value of 0.836 it held the 26th place.

To obtain detailed information and a more visual presentation of Russia's positions, we can consider the data on the ICT Development Index as an example (Table 3).

The data presented for the period of 2008–2017 indicate a number of essential points: firstly, the growth of the countries participating in the rating from 152 to 176 countries; secondly, the growth of the highest index values from 7.8 to 8.98; thirdly, the growth of the lowest index values from 0.79 to 0.96.

When analyzing Russia's position in this rating, it should be noted that, on the whole, it has improved slightly over the period: from 49th to 45th place, but within the period, the highest 38th place was occupied in 2011, after which there is a noticeable gradual deterioration of the position, although the value of the ICT Index

Table 3 ICT development index

	2008	2010	2011	2012	2013	2015	2016	2017
Number of countries that participated in the ranking	152	166	157	166	166	175	176	176
Highest value (first place)	7.8	8.64	8.51	8.81	8.86	8.78	8.8	8.98
Lowest value (last place)	0.79	0.88	0.93	0.93	0.96	1	0.89	0.96
Russia's place in the ranking	49	46	38	41	42	42	43	45
Value of ICT in Russia	4.42	5.57	5.94	6.48	6.7	6.79	6.91	7.07

Compiled by [10, 11]

itself showed a steady growth from 4.42 to 7.07, which may be associated with the growth of the values of the index itself for most participating countries.

Analysis of another index, the Digital Economy and Society Index, calculated by the Statistical Service of the European Union [12], showed that its value for Russia increased from 0.35 to 0.48 in the period from 2013 to 2016, showing unstable dynamics within the period under review. At this, it should be mentioned that the index values for Russia slightly exceeded the minimum values with the maximum convergence in 2015. At the same time, the lag of the Russian index from the upper values decreased from 0.33 in 2013 to 0.28 in 2016.

To assess the situation with regard to the level of development of the information society at the level of constituent entities, the data of the first rating of the constituent entities of the Russian Federation made by the end of 2016 were analyzed. Its results established five leading actors in the field of informatization. These are the capital cities of Moscow and St. Petersburg, two regions closely connected with oil and gas production: Khanty-Mansiysk Autonomous Okrug—Yugra and Yamalo-Nenets Autonomous Okrug and Kaliningrad Region —a region that has established itself as one of the most dynamically developing in recent years.

The authors' calculations of the ICT Development Index both for each constituent entity of the Russian Federation and for the federal districts in general made it possible to make and analyze the rating of federal districts by the values of sub-indexes composing the ICT Development Index (Table 4).

The analysis of ratings of federal districts by values of components of the ICT Development Index has shown that the leader in the field of informatization during the period considered in the research was the Central Federal District, and the most lagging one—the North Caucasian District. The rest of the federal districts had an unstable position in the ICT Development Index component rankings, which makes it impossible to determine their place in the component rankings (Table 5).

Table 4 Ratings of federal districts of the Russian Federation by components of the ICT development index

Federal district	2014			2015			2016			2017			2018		
	SI_1	SI_2	SI_3	SI_1	SI_2	SI_3	SI_1	SI_2	SI_3	SI_1	SI_2	SI_3	SI_1	SI_2	SI_3
Central	2	**1**	**1**	2	**1**	**1**	2	5	**1**	**1**	**1**	**1**	**1**	**1**	**1**
Northwestern	**1**	5	2	**1**	4	3	**1**	3	2	2	3	3.5	2	4	3

8 - minimum rating value

Table 5 Positions of federal districts of the Russian Federation by the value of the ICT development index for 2014–2018

Federal district	2014		2018		Absolute change for 2014–2018, points
	Indicator value	Place in the ranking	Indicator value	Place in the ranking	
Central	5.73	**1**	6.28	**1**	+0.55
Northwestern	5.69	2	6.05	2	+0.36
Southern	5.32	5	5.57	7	+0.25
North Caucasian	4.62	**8**	5.13	**8**	+0.51
Volga	5.26	6	5.78	4	+0.52
Ural	5.41	3	5.86	3	+0.45
Siberian	5.17	7	5.65	6	+0.48
Far Eastern	5.40	4	5.77	5	+0.34

1 - maximum rating value;
8 - minimum rating value

The analysis of macroeconomic indicators of the ICT sector showed the following results. In terms of the ratio of investments to GVA in the sector as a whole the growth was 17.2 p.p., including the largest growth which was recorded in "provision of other information services"—60.9 p.p., and in the field of "ICT production"—only 1.2 p.p., which indicates extremely uneven dynamics of indicators.

Comparison of growth intensity of "GVA per employee" and "Investments per employee" indicators is faster than the growth of the first one. At the same time, if in the sector as a whole the growth rate was almost a third of the values—29.8%, it is also uneven and varies from 13.0% in the sphere "ICT production" to 62.9% in the sphere "Information technology". In terms of "Investment per employee" the growth is noticeably lagging behind – only 10.2% in the sector, while in some areas one can see not only the variability of growth in intensity from 6.25% in "Activities in the field of communications" to 22.35% in "Information technology" sector, but also the multidirectional dynamics, reflected in a decrease of 0.89% in the value of the indicator for "Other information services".

In the sector as a whole, the volume of gross value added in the period from 2010 to 2018 increased from 2,273.9 billion rubles to 2,443.1 billion rubles, an increase of 7.4%. Out of the presented types of activities, the highest growth rate was recorded in the field of "Information technology"—by 13.3% and amounted to 641.2 billion rubles in 2018, the lowest growth rate was recorded in "ICT production"—4.5% (in 2010–910.9 billion rubles; in 2018–954.4 billion rubles).

The highest growth rates are observed in the volume of investments in the studied sector of economy. Thus, in 2010 the total volume of investments made 475 billion rubles, and in 2018 it was 598.3 billion rubles; in absolute terms the growth made 123.3 billion rubles, which is 26.0%. Out of the ICT sector components, the highest

relative growth was recorded in "Other information services" by 68.3%, while the lowest growth was recorded in "ICT production" by 5.8%.

The total number of employed people decreased by 36.2 thousand or 3.0% between 2017 and 2018 alone. Such dynamics can be traced in most spheres of the sector's activity, with the exception of "Provision of other information services"—there was a growth of 5.6%—and "Wholesale of ICT-related goods".

4 Conclusions/Recommendations

The study carried out by the authors of information and analytical support for the development of the digital economy found that, despite the conceptual commonality in the methodology of the study, there are differences in the composition of indicators calculated at the international and national levels. In addition, at the national level, there is a need to harmonize the content of indicators submitted by different agencies. A system of indicators to monitor the development of the digital economy has been developed at the state level. Of the 38 indicators included in the system, only seven have been officially approved.

The results of the analysis showed that despite the growth of volume and analytical indicators reflecting qualitative changes in various areas where ICT and digital technologies are used, there is a significant gap with the leading countries of the world; within the ICT sector, there is a variation in the intensity of dynamics indicators reflecting various aspects of the information society development and ICT implementation in all spheres of society.

The analysis of Russia's position in various ratings compiled by international organizations has shown a significant gap with the leading countries.

The results indicate the need for further work to improve indicators for monitoring the digital economy.

Improving the Level of Digital Maturity of the Company (Based on Example of Reckitt Benckiser Group PLC)

Elena V. Kuptsova, Valeriy V. Maslennikov, and Irina A. Kalinina

Abstract The article presents digital tools that can impact the overall performance of the company positively. It also considers the standard as well as the digital value chain, and it is visualized how digitalization accelerates all processes. The stages of the value creation process are detailed, and during the stages digitalization accelerates and improves the processes. The impact of digitalization on the company is illustrated using an assessment of the current level and the expected level of digital maturity of the company after the introduction of digital tools. Critical success factors are formed, as well as digital competences of management are underlined.

1 Relevance of Assessing the Digital Maturity of the Company

Digitalization is now a global trend, and in order to be competitive in the marketplace, many companies are seeking to integrate digital technology into their daily operations.

One of the main innovators in the field of digitalization are global companies, for which it is essential to do business in a coherent manner in different countries. This is why digitalization is the most pressing issue for them [1].

Modern technologies allow to improve the processes inside the organization literally at each stage of the value chain. The few problems that the organization faces

every day prove once again that there is already a need to implement digital technologies in order to be competitive in the market, to improve the quality of their products, to increase employee loyalty to the company by facilitating routine operations or reducing the time to perform them. Moreover, digital technologies make it possible to minimize the risk of human error, which has a direct positive impact on the efficiency of the company as a whole.

2 State of the Research Problem

The issue of assessing digital maturity is of interest to many researchers. For example, a number of authors believe that productivity improvement is a problem for all companies, not for a set of individual manufacturing companies. On this basis, A. Pulkkinen proposed the concept of Digital Extended Enterprise, which identifies the components of digitalization, lean manufacturing and extended enterprise. The Digital Extended Enterprise maturity assessment model includes five levels of maturity defined by 69 statements in key business areas: strategy, business model, processes, performance indicators, interfaces and information flows [2].

The digital transformation of the productive sector creates the conditions for major industrial changes [3]. These days, Colli [4] proposes several maturity models to evaluate the need to support companies in this transformation. These include standardized questionnaires that result in an assessment of the current maturity stage and a set of general recommendations for improvement in accordance with it. However, a more individual approach is needed to provide more tangible support to companies.

Assessment of digital maturity is also interesting for industrial decision makers who are willing to invest in the digital transformation of their company [5]. At present, Industry 4.0 lacks digital knowledge of the company and strategic guidelines for its development. The Andreas Schumacher model [3] is based on an assessment of the maturity of 65 critical success factors in Industry 4.0.

Tobias Mettler and others [5] argue that recently there has been interest in assessing the digital maturity of hospitals, but evidence of the significance and evolution of digital maturity is still lacking, and researchers have not found a direct effect of investment in transformation management measures.

3 Description of the Object of Study

The article analyzes the activities of the British-Dutch company Reckett Benckiser, which produces consumer goods. The company was founded in December 1999 with headquarters in Slough, UK [6].

Reckitt Benckiser Group Plc (hereinafter referred to as RB) manufactures and sells health care, hygiene and home cleaning products. It sells a wide range of products in more than 200 countries.

The company's trademarks (brands) include air fresheners, household cleaners, laundry detergents, furniture polishes and dishwashing products. The company also manufactures over-the-counter pharmaceuticals such as analgesics, antiseptics, flu products and offers more targeted products such as denture cleaners and insect repellents.

The company's business is structured and conventionally divided into three geographical segments:

- Europe and North America (ENA);
- Latin America, North Asia, Southeast Asia and Australia and New Zealand (LAPAC);
- Russia and CIS, Middle East, North Africa, Turkey and Sub-Saharan Africa.

In order to manage products, each region has branches of the parent company, which are engaged in adaptation of existing products, less frequently, development of new ones, market research, management of stocks of finished products as well as distribution, logistics, marketing and sales.

This study will focus on the Cleaning and Detergents business unit. Before proceeding with the digital maturity analysis of Reckitt Benckiser, it is necessary to form a base of important terms on which further analysis will be based.

(1) Digitalization is the introduction of modern technologies in the business processes of the enterprise, which implies not only the installation of modern equipment and software, but also the transformation of approaches to management and corporate culture [7].
(2) Digital economy is activities related to the creation, dissemination and use of digital technologies and related products and services.
(3) Digital technology is technology for the collection, storage, processing, search, transmission and presentation of data in electronic form [8].
(4) Digital manufacturing clone is a digital copy of a physical object or process that helps to optimize business efficiency [9].
(5) Big data is technologies of collection, processing and storage of structured and unstructured information, characterized by a significant volume and rapid rate of change (including in real time), which requires special tools and methods of working with them.
(6) New manufacturing technologies are technologies for digitalization of production processes that increase resource efficiency, as well as production of individual items whose value is comparable to the value of mass production goods [8].
(7) Artificial Intelligence is a field of computer science that deals with the development of intelligent computer systems, i.e. systems with capabilities that we traditionally associate with the human mind—understanding language, learning, ability to reason, solve problems, etc. [10].
(8) Digital strategy is the process of formulating the goals of a company or brand and planning to achieve them through digital technology.

(9) Cloud technology is a way of handling data when computer resources are presented as an online service (all data is not stored on the user's computer, but on a remote server).

In order to fully assess the level of digital maturity of a company (using the example of the Cleaning and Detergents business unit), it is necessary to visualize the existing value chain within a business unit (Fig. 1).

At the moment, the SAP system is the main software used for procurement, production planning and monitoring of raw materials and finished products in the warehouse. SAP is the software that allows to regulate the activity of all departments of the organization within one system.

Within SAP, the following departments interact:

- **Accounting and Finance** is responsible for control over the timely establishment of an purchase order of goods/services, as well as making payments for existing projects on the basis of a certificate, invoice issued by the supplier, balance sheet control, which is automatically generated when a purchase order is created (necessary costs are transferred to a certain line in the balance sheet when establishing a purchase order), as well as control of all incoming cash flows from the sale of products to the company's customers—retailers and distributors.
- **Customer Relationship Management (CRM systems)** allows to monitor in real time whether and to what extent orders placed by customers are delivered on time. Subsequently, the system allows you to generate reports on the quality of services provided.
- **Budgeting**—based on the created purchase orders, SAP makes it possible to track the costs that are incurred from the budget of each department or brand; in total, all individual budgets are consolidated into one budget of a particular company.
- **Human Resources Management (HR)**—SAP also employs human resources services within the system by entering the "card" of each employee into the system, assigning him/her an identification number, which is later used within the system to calculate salaries, monitor the number of days of paid rest, generate reports on business trips, etc.
- **Supply Management**—within the system, the employees of the supply department monitor daily the finished product balances, the production plan for the next periods for which raw materials should be ordered, as well as monitor the arrival of raw materials at the warehouse.
- **Production Management**—within the SAP system, planning department staff place their production plans, according to which the production department staff draw the production schedule for a certain type of product, so that within one system it is possible to trace the path of production from the moment the plan is placed to the moment it appears in the finished product warehouse.
- **Warehouse Management**—SAP allows to monitor not only the filling of warehouses, but also to track the shelf life of finished products, which helps to quickly plan what products need to be shipped from the warehouse to the customer in the first place.

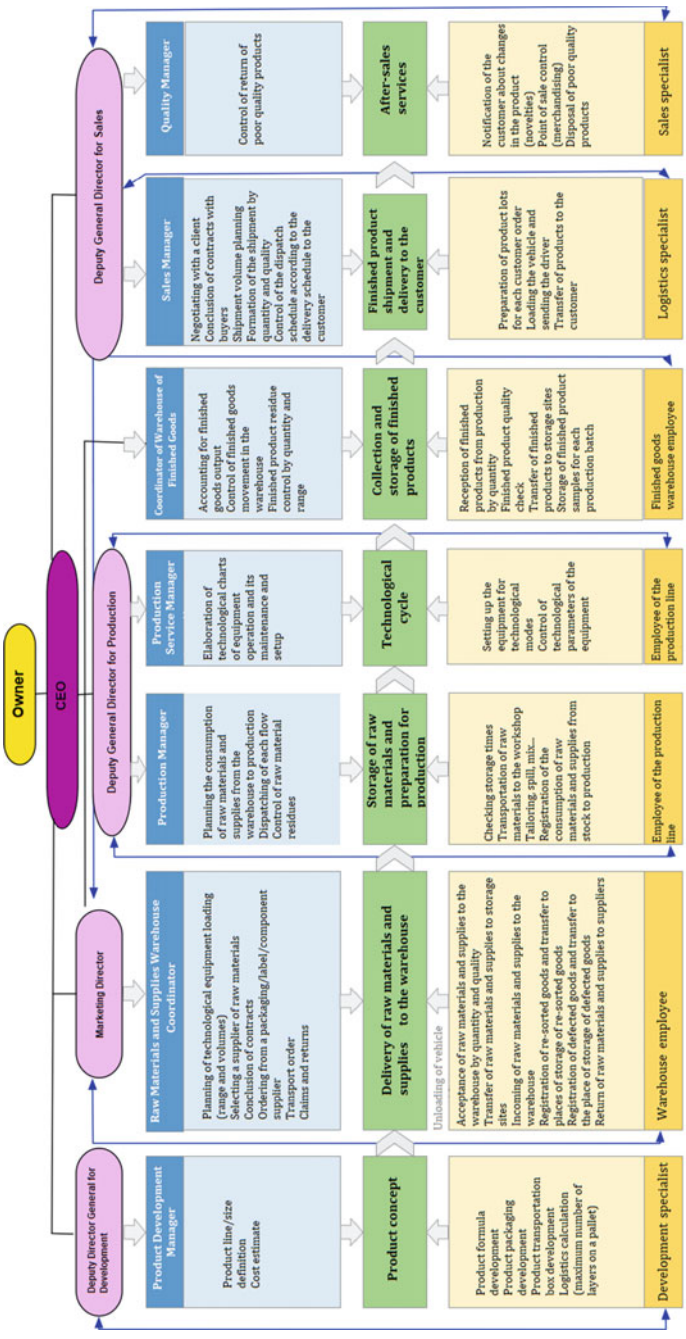

Fig. 1 Reckitt benckiser value chain on the example of the cleaning and detergents business unit. *Source* Developed by the author

Thus, for RB SAP is the main digital system, which concentrates the activities of all departments of the company, from the moment the supplier of raw materials is established in the system by the purchasing department, to the production of finished products and their release from the warehouse.

It should also be noted that SAP allows interaction not only between departments within the same company in a particular country, but it also helps to connect employees of absolutely all functions and business units in the world, which is especially important for the production of imported products.

Each individual country can place its plans in the system and be sure that an imported product will be produced and delivered for the needs of a particular market.

However, SAP is not in every respect an ideal system for daily work. Many operations have to be done manually or using systems such as Excel.

Let's consider the prospects of implementing modern digitalization systems on the example of specific departments:

- **Planning Department** uses Excel for its forecasts and comparable period sales data for the previous year, uploaded from SAP. Further, all data is transferred to Excel tables and based on the promo plan and last year's data, a sales forecast for the coming months is manually generated. The planning horizon is a period of 3 months.
- **Supply Department (work with raw materials warehouse)**—all material flow and shelf life are monitored manually, which is not always convenient, as the monitoring should be performed on a regular basis; all requests are generated manually, which takes time for employees to perform routine operations, and there is no possibility to quickly see the summary of all products/ingredients, all information can be obtained only on request.

Moreover, the need to order a particular material (flavor, label) is also identified manually when accessing the corresponding transaction in SAP.

- **Supply Department (work with finished goods warehouse)**— the shelf life of finished products and the number of products with critical shelf life is also checked manually or on request, which does not always allow to respond quickly to the need to urgently sell products with critical shelf life. Therefore, from the point of view of work with finished products, it is advised to plan marketing activities, such as, for example, promotions among customers for a particular type of product.

All of the above problems—one of many that can be solved by the digitalization, because modern technology has stepped far ahead, and with the appropriate competent approach it can automate many routine operations, improve their quality, while in many cases reducing costs.

The main difficulty may be the introduction of new technologies in the daily activities of the company, because it is necessary to re-equip not one, but many offices around the world.

Figure 2 shows a comparison of analogue and digital processes at each stage of value creation, illustrating which processes and microprocesses can be upgraded.

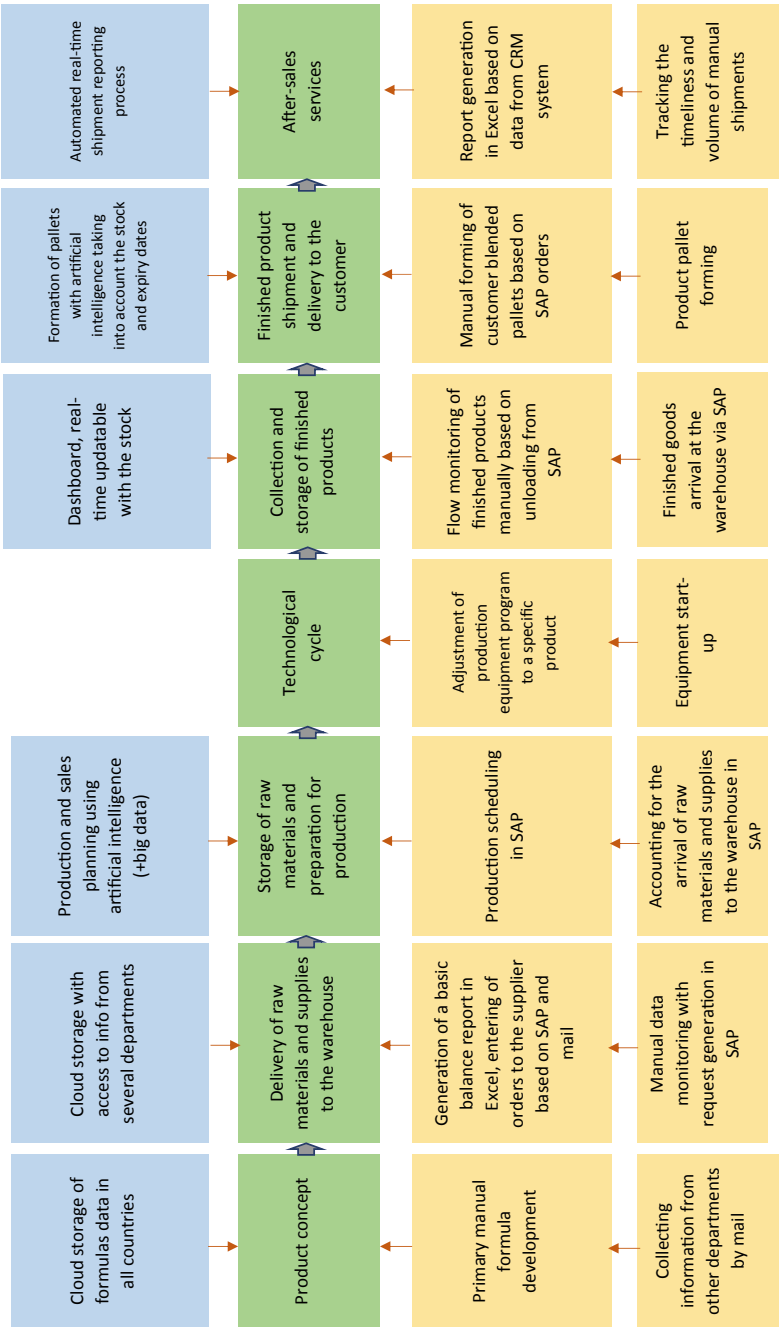

Fig. 2 Analogue and digital value chain variants. *Source* Developed by the author

Thus, it is clear that digitalization tools can be applied at the following stages of the value chain:

(1) **Product concept**—at this stage the formula and packaging of products are developed. But since RB is a global company, many product formulas or packaging are recreated in Russia based on formulas from other countries. To accelerate communication and the development process, it is necessary to implement cloud storage systems to which all countries' development staff have access.
(2) **Supply of raw materials to the warehouse**—at this stage cloud technology can also be applied, where data on all remaining raw materials and supplies are stored. This approach will speed up the work not only of the supply department, but also of other departments, such as planning and development. The ability to see all the data in one system will allow to avoid unnecessary mail communications that slow down the work process.
(3) **Storage of raw materials, preparation for production**—at this stage artificial intelligence can be used to simplify and optimize the planning process in preparation for production. Instead of manually collecting all data of previous periods, and also all data on planned promo-activities, further applying a certain factor of increase/decrease in predicted volume of sales, application of artificial intelligence with function of self-training that would allow to unload people, to avoid search for a human error, and also to increase accuracy of the prediction is possible.
(4) **Technological cycle**—since all plants are already provided with all necessary modern equipment for production, there is no urgent need to invest in digitalization for this stage of the value chain.
(5) **Receipt and storage of finished products**—in order to optimize the work of the planning department (raw materials and production) and the planning department, it is necessary to implement a dashboard (interactive board with information), which would display all the necessary basic information about the amount of finished products in the warehouse, the planned production, as well as the need to plan a new production to meet the demand placed by the sales department.
(6) **Sending finished products and delivery to the customer**—for the formation of shipments from the production warehouse to the client, it is also possible to use the system of artificial intelligence, which would suggest how to most effectively place the goods on the pallet from the logistical point of view, and what goods should be taken out of the warehouse in the first place (in terms of expiry dates).
(7) **After-sales service**—to improve the quality of shipments, the company has the need to monitor which shipments were delivered on time and to what extent; if something was not delivered, then for what reason (it was not in stock, there were no trucks for delivery). In order to generate reports in real time, it is necessary to implement a system that will automatically generate information from SAP in the required form.

Before introduction of new digital tools, it is necessary to estimate level of digital maturity of the company before introduction of innovative working methods and after—this will allow to estimate efficiency of actions.

To estimate the level of digital maturity of the company, the Digital Transformation Index (Digital Transformation Index developed by the analytical agency Arthur D. Little) was chosen [11].

According to this methodology, the evaluation is conducted by experts (both internal and external) on 7 criteria: Strategy and Management, Products and Services, Customer Management, Operations and Supply Chain, Corporate Services and Control, Information Technology, Workplace and Culture.

Given the specifics of Reckitt Benckiser, special attention should be paid to the criteria that have a direct impact on the value chain, and which will be directly related to the process of digitalization of the organization.

Products and Services—as described above, the product creation process can and should be upgraded to accelerate the product development process.

Customer Management—quality control of product deliveries to the customer is an integral part of the daily work of the planning department, and also has a direct impact on the image of the company and RB's relationship with the customer, which is why it is important to monitor the quality level of services provided for the transportation of finished products as closely as possible.

Operations and Supply Chain—for a FMCG company, it is very important to have well-established production processes that are impossible without well-established supply chains (raw materials, packaging, labels, etc.). To minimize order errors and meet deadlines, the company needs digitalization tools.

Corporate Services and Control—for the effective work of the entire company, as well as for the coordination of the office with the factory and with the client within the organization, it is necessary to have well-established means of communication and interaction.

Information Technology—in large organizations that have many offices in different countries, it is vital to have different information and digitalization tools for effective work and communication [11].

As described above, prior to the introduction of digitalization tools it is necessary to assess the level of digital maturity of the company, so that in the future it is possible to compare the results obtained with the results after the introduction of the latest tools.

A team of 7 experts from different departments of the company (marketing, sales, supply, logistics, planning and quality control, trade marketing and category management) was involved in the evaluation. For each of the criteria, the experts were asked to give a rating between 1 and 5, where 1 is "not satisfactory" and 5 is "in excellent condition".

The weight of each of the criteria was determined by RB management.

The following results were obtained during the digital maturity test (presented in Table 1).

In the course of the study, experts found that the digital maturity level of Reckitt Benckiser is currently 3.51 points (Fig. 3).

Table 1 Company digital maturity level before digitalization

No	Criterion	Weight	Expert 1	Expert 2	Expert 3	Expert 4	Expert 5	Expert 6	Expert 7	Average score	Total
1	strategy and management	0.07	3	4	3	3	4	4	5	3.7	0.26
2	poducts and services	0.17	4	4	4	5	5	4	3	4.1	0.70
3	customer management	0.17	2	3	3	4	3	3	3	3.0	0.51
4	operations and supply chains	0.17	3	3	4	3	3	3	4	3.3	0.56
5	corporate services and control	0.20	3	3	3	4	4	4	3	3.4	0.69
6	information technology	0.15	2	3	3	3	4	4	3	3.1	0.47
7	workplace and culture	0.07	4	4	4	5	5	5	5	4.6	0.32
Total score		1.00									3.51

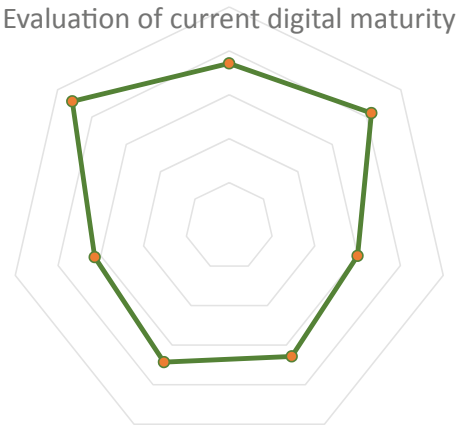

Fig. 3 Current level of digital maturity of RB according to digital transformation index criteria

Afterwards, the experts were explained which set of measures is planned to be implemented to improve efficiency, and which digitalization tools are planned to be used. After a detailed description of the set of measures, the experts were asked to reassess the compliance of the situation inside the company with the digital maturity criteria. After the survey was repeated, the experts made the following assessments (Table 2).

After the second survey, it can be seen that the total score of experts increased from 3.51 to 4.48 (improvement of 0.97 points).

Moreover, it was found that the total increase in the assessment was due to all indicators, but especially those that are key for RB.

It was also found that all scores were close to 5, which is undoubtedly a positive result of the digitization process, which is designed not only to improve the efficiency of production and other internal processes, but also to increase employee satisfaction with the work process due to the fact that some routine operations will be transferred to PCs and various modern programs (Fig. 4).

It is important to note that each company has critical success factors, Reckitt Benckiser has them as follows:

- Flexible interaction across departments
- Flexibility in product launch/restart dates
- Relative independence from headquarters
- Integrated value chain
- Aspiration for digital business improvement.

The whole process of digitalization is an integral part of the evolution of business and the market as a whole, which is why managers need to adjust to current trends to be in demand on the labor market.

The key competencies of the future manager are the following: the ability to quickly learn and adapt to a new pace of work, the ability to work with scarce

Table 2 Company digital maturity level after digitalization

No	Criterion	Weight	Expert 1	Expert 2	Expert 3	Expert 4	Expert 5	Expert 6	Expert 7	Average score	Total
1	strategy and management	0.07	4	5	4	4	5	5	5	4.6	0.32
2	poducts and services	0.17	5	5	5	5	5	5	4	4.9	0.83
3	customer management	0.17	3	4	4	5	4	4	4	4.0	0.68
4	operations and supply chains	0.17	4	4	5	4	4	4	5	4.3	0.73
5	corporate services and control	0.20	4	4	4	5	5	5	4	4.4	0.89
6	information technology	0.15	4	4	4	5	5	5	5	4.6	0.69
7	workplace and culture	0.07	5	5	5	5	5	5	5	5.0	0.35
Total score		1.00									4.48

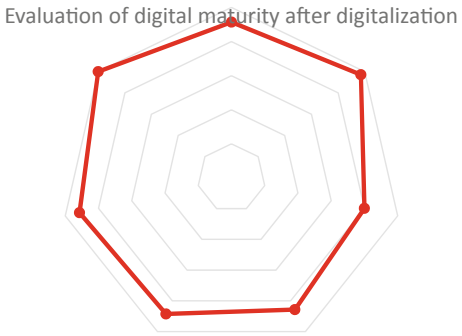

Fig. 4 Expected level of digital maturity of RB by criteria of digital transformation index after digitization

resources, the ability to operate in an uncertain and rapidly changing environment, the desire to minimize losses and save time in all processes.

Digital Technology for Vehicle Safety

Andrey G. Lipatov, Olga A. Tettsoeva, and Mohamed Conde

Abstract The ongoing evolution of automotive technology aims to provide even greater safety benefits and Automated Driving Systems (ADS) that—one day—can handle the entire challenge of driving when we do not want to or cannot do it ourselves. Fully automated cars and trucks that drive us, not driven by us, become reality. These intelligent vehicles will eventually be integrated into the transport infrastructure and become an integral part of a single transport system. It should be noted that only by means of automation (autopilot) a reduction of 80–90% in necessary vehicles is achieved, operating costs for carriers are reduced by 30% due to non-stop traffic—according to EU data. This initiative should develop through the intersection of spheres of interest. A project to develop digital transport and logistics in Russia has been launched. The digital platform of the transport complex of the Russian Federation exists as an essential part of the "Digital Economy" project in Russia. At present, it is obvious that the Russian transport complex is characterized by partial platforming. Today there is no true "digital" transport and logistics. In order to develop more comprehensive solutions, it is necessary to create a single data space (information and communication space). Taking into account modern technologies, it is reasonable to develop such an environment based on Blockchain technology (distributed registry, network).

1 Introduction

Some of modern cars have a technology that helps drivers avoid skidding into adjacent lanes or dangerous lane changes, or warns drivers of other vehicles behind them when they back up, or automatically brakes if the car in front of them stops or brakes sharply. These and other safety technologies use a combination of hardware (sensors, cameras and radar) and software to help vehicles identify certain safety risks so that they can warn the driver to act to avoid an accident [1].

The ongoing evolution of automotive technology aims to provide even greater safety and—one day—to deliver Automated Driving Systems (ADS) that can handle the entire driving task when we do not want to or cannot do it ourselves [2].

2 Methodology

The article is based on the processing of statistical data on the application of artificial intelligence to the car and its components based on the analysis of theoretical and empirical methods of driving vehicles, as well as the conclusions drawn from the generalization of experience in the use of ADS in our country and in the world. The results of the brainstorming and strategic sessions, in which the authors of the article were directly involved, form the basis of the conclusions drawn.

3 Results and Discussion

3.1 Main Stages of Digital Technology Development in Motor Vehicle

There are five main stages in the development of digital technologies for motor vehicles.

First stage: 1950–2000.

Development of safety and driver comfort functions. The first means of monitoring the movement of vehicles include cruise control, seatbelt monitoring, antilock brake system.

Second stage: 2000–2010.

Expanding the use of safety features on the road. Innovations include electronic stability control, blind spot detection, remote control of collision warning, lane departure control.

Third stage: 2010–2016.

Comprehensive implementation of rearview and parking video systems, automated emergency braking based on electronic distance assessment, automatic emergency braking at a pedestrian crossing, development of a lane traffic system [3].

Fourth stage: 2016–2025.

Introduction of an automated GPS navigation system that provides road safety functions, the use of adaptive cruise control, hybrid circuitry when in traffic jams, fully independent parking.

Fifth stage: 2025+.

Use of fully automated highway safety and autopilot functions.

Fully autonomous cars and trucks that drive us, not us, will become reality. These self-propelled vehicles will eventually be integrated into US roads, passing through six levels of driver assistance technology in the coming years. This includes everything from lack of automation (when a fully engaged driver is required) to full autonomy (when an automated vehicle operates independently, without human involvement).

3.2 Basic Levels of Motor Vehicle Control Automation

The following levels of automation can be distinguished for the driver.

Level 0: man-driver does everything behind the wheel.

Level 1: Advanced Driver Assistance System (ADAS) in a vehicle can sometimes help the human to drive or brake/speed up, but not simultaneously.

Level 2: ADAS can control both steering and braking (speeding-up) simultaneously in some cases. The created interactive "Driver-Man" environment must continue to operate the car autonomously.

Level 3: Automated Driving System (ADS) integrated into the vehicle fulfills all driving tasks based on the road situation and changes in the external environment. In this mode, the vehicle driver can request manual driving based on the road situation and the operating mode of the system.

Level 4: ADS autonomously performs all operations of vehicle driving and controls the external environment—carrying out the process of adaptive driving independently (for example, obstacles in the flow of moving cars).

Level 5: ADS can perform the whole process of driving under any circumstances. People are just passengers, and they don't need to be involved in the driving. Automated vehicles have safety advantages which are vital on the road. The potential of automated vehicles to save lives and reduce injuries is grounded in one critical and tragic fact: 94% of serious accidents are caused by human error. Figure 1 shows a general picture of the interaction between the vehicle and the ADS system [4].

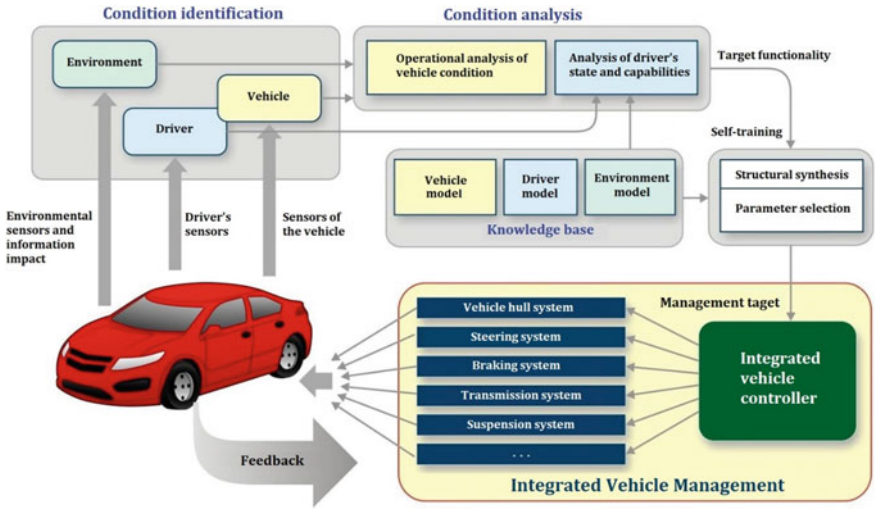

Fig. 1 Vehicle's interaction with the environment and the ADS system

3.3 Accident Statistics in the Russian Federation

Automated vehicles have the potential to eliminate human error from accidents and contingencies, creating an additional safety milestone for drivers, passengers, cyclists and pedestrians [5]. Thus, the total number of road accidents in 2019 with the victims and the dead was 147,739 people. As a result of accidents, 15,159 people died and 189,671 were seriously injured.

The root cause of serious consequences of road accidents is violation of traffic rules by drivers. Due to careless driving, in 2019 there were 131,925 road accidents, in which 12,854 people died and 185,326 people were injured. This figure is 89·23% of the total number of accidents. And this indicator with small deviations remains at one level from year to year. The unwillingness of vehicle drivers to comply with traffic rules is the main reason for such high mortality rates on the roads. The main causes of accidents due to violations of the rules by drivers are: failure to follow the queue at intersections (about 20% of the total number of accidents), wrong choice of distance (10·1%), violation of the rules of crossing pedestrian crossings (10·2%), driving on the oncoming lane (8·2%), speeding (5·8%), red light run (2·7%), exceeding the set speed (2·3%), violation of overtaking rules (1·3%).

The second concomitant cause of the accidents, based on statistical data, is violation of the requirements for the operational condition of roads and railway crossings. Thus, unsatisfactory road conditions were recorded in 48,259 accidents. In such cases, 4,317 people died and 61,637 were injured. This figure accounts for about one third of all road accidents in the country. The main types of unsatisfactory road

conditions include poor road marking (57·1% of all accidents), poor winter maintenance (13·7%), lack of road signs (21·9%) and pedestrian fences in the necessary places (9·8%), incorrect use, poor visibility of road signs (9·4%).

The third place among the causes of traffic accidents is occupied by pedestrian traffic violations. There were 16,601 such accidents, 2,954 people died and 13,760 people were injured. Of the total number of accidents, the share of accidents in which the pedestrian is responsible is 10·56%, i.e. every tenth accident is the fault of a pedestrian. The main types of accidents caused by pedestrians are: crossing the road in an unspecified place, red light run, driving on the side of the road in the course of the car, failure to comply with safety requirements when crossing or driving on the side of the road in the dark, crossing the road without paying attention to the weather conditions (for example, during the ice pedestrians may not take into account that the length of the braking path of the car significantly increases, and the driver may lose control during hard braking).

A significant proportion of road accidents are caused by the operation of emergency vehicles. Road traffic accidents with significant deviations in the technical parameters of vehicles or conditions under which their operation is prohibited amounted to 5·2% of the total number. A total of 7,322 such cases were registered in the country, in which 1,025 people were killed and 7,424 were injured. Their main types of malfunctions include the installation of tires of different sizes, designs, tire models, tires with different tread patterns, as well as the installation of incorrectly studded and non-studded tires on vehicles operated in summer (specific weight 25·2%), the presence of unidentified design changes, information about which is absent in the documents for the car (21·7%), the malfunction of the main lighting devices (14·9%) and additional lighting equipment (11·1%).

An important factor in traffic accidents is the impact of weather conditions. This indicator is not reflected in the State Traffic Safety Inspectorate statistics, as it is not taken into account as a cause of accidents. And in case of unfavorable weather conditions, as a rule, it all comes down to the driver's fault, indicating the violation of traffic regulations, namely the insidious point 10·1 of the traffic rules, according to which the driver must drive the vehicle taking into account the weather conditions, and if there is a danger to traffic, he must take possible measures to reduce the speed of the vehicle or even stop it [6]. Therefore, let's list the reasons that can lead to an accident under bad weather conditions. The total number of accidents and their structure are shown in Fig. 2.

3.4 The Impact of the Use of Digital Information Technology on Road Accidents and Injuries

Automated vehicles can bring additional economic benefits. The NHTSA study found that motor vehicle accidents caused an economic loss of $234 billion, including

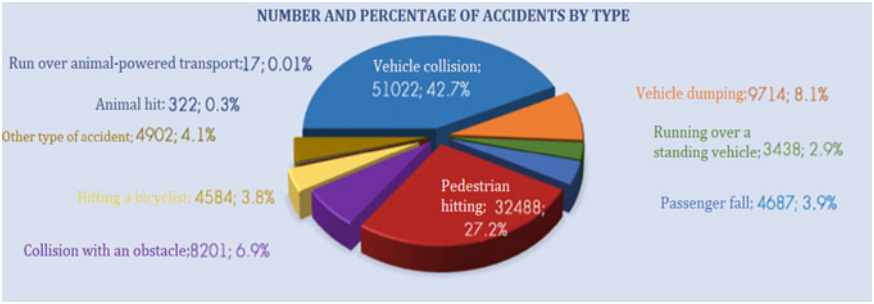

Fig. 2 Number of accidents and their structure

$57·6 billion in lost productivity and $594 billion due to deaths and loss of quality of life due to injuries. Eliminating the vast majority of car accidents can wipe out these costs.

Roads filled with automated vehicles could also contribute to smoothing traffic flow and reducing traffic jams. In 2014, Americans spent about 6·9 billion hours on traffic delays, reducing time at work or with their families, increasing fuel costs and vehicle emissions. With automated vehicles, the time and money spent on the road could be used better. Comprehensive traffic flow surveys have shown that automated vehicles can free up to 50 min a day, which were previously dedicated to driving.

While its full social benefits are difficult to predict, the transformational potential of automated vehicles and their driver assistance functions can also be understood by analyzing the demographics of the United States and the communities that can support these technologies. For example, automated vehicles can also provide new mobility opportunities for millions of people. Today, there are 49 million Americans over the age of 65, and 53 million people have some form of disability.

Nowadays, the car is becoming more and more important in the life of every person and every family. Automated vehicles could extend this freedom to millions more people. One study suggests that the mobility of approximately 2 million people with disabilities will soon be supported. NHTSA is promoting the lifesaving potential of new transportation technologies.

Through its proactive and comprehensive approach to safely developing, testing and deploying new and advanced transportation technologies that have the potential to enhance safety and mobility for all Americans, NHTSA is demonstrating its commitment to saving lives on our country's roads and highways.

In September 2016, NHTSA and the U.S. Department of Transportation issued a federal Automated Vehicle Policy that outlines a proactive approach to safety and innovation. Guided by this policy and taking into account feedback from public comments, stakeholder meetings and hearings in Congress, in September 2017 the agency published the book "Automated Driving Systems 2·0: A Vision for Safety". Updated guideline 2·0 offers a flexible, nonregulatory approach to the security of automated transport technologies, supporting the automotive industry and other key stakeholders when they consider and develop best practices for safe testing and

deployment of ADS levels 3–5. It also provides technical assistance to states and best practices in advertising to developers.

3.5 Key Trends in ADS Systems

In October 2018, the American DOT released the book "Preparing for the Future of Transportation: Automated Vehicles 3·0", which is based on the voluntary guidance provided in version 2·0, but does not replace it. AV 3·0 expands the scope for all land transport systems on the road and was developed based on contributions from various stakeholders throughout the country. AV 3·0 is structured around three key areas:

1. increase in multimodal safety;
2. reducing political uncertainty;
3. outlining the process of working with the American DOT.

American DOT sees AV 3·0 as the beginning of a national discussion about the future of our land transportation system on the road. As automated technologies evolve, so will the leadership of the department. The leadership is designed to be flexible and evolve as technology advances, but safety is always a top priority.

All design solutions must be tested, validated and verified as separate subsystems and as part of the entire vehicle architecture.

Manufacturers are advised to document the entire process; all actions, changes, design choices, analysis, related testing and data should be traceable and transparent.

Understanding the interaction between the vehicle and the driver, commonly referred to as the Human-Machine Interface (HMI), has always played an important role in the design process of cars.

The new complexity is introduced into this interaction as ADSs take over driving functions, partly because in some cases the car must be able to accurately transmit information to the human-driver about the intentions and characteristics of the vehicle. This is especially true for ADSs, where human-drivers can be asked to perform any part of the driving task. For example, in a Level 3 vehicle, the driver must always be receptive to the system's request to take back the driver's responsibilities. However, the driver's ability to do so is limited by their ability to remain alert to the task of driving and thus be able to take over quickly while not actually performing the task of driving until it is offered by the vehicle. Individuals are encouraged to consider whether it is wise and appropriate to include monitoring of driver interaction where drivers may be involved in the task of driving in order to assess the driver's awareness and readiness for a full driving assignment. Manufacturers are also advised to review and document the process for evaluating, testing and technological preparation of smart vehicles for mass production.

It should be taken into account that the driver interacts with other vehicles (both traditional and intelligent transport systems). The system should provide for the transfer of information relating to the status of ADS operation, it has to do with the

various interactions that take place in the system and how this information should be communicated. In vehicles that are not expected to have driver controls, it is recommended that HMI will be developed to accommodate people with disabilities (e.g. through visual, auditory and tactile displays). Nineteen vehicles in which advertisements may be designed to operate without a human driver or even any human passenger, remote dispatcher or central control body, if such a body exists, should be able to know the status of advertisements at any time. Such examples may include unoccupied SAE 4 or 5 vehicles, automated delivery vehicles, Last Mile delivery solutions, drones range and automated maintenance vehicles.

Given current research and the rapidly evolving nature of this market segment, organizations are encouraged to consider and apply voluntary guidelines, best practices and design principles published by SAE International, ISO, NHTSA, the American National Standards Institute (ANSI), the International Commission on Illumination (CIE) and other relevant organizations, based on the level of automation and the expected level of driver involvement.

Developers are encouraged to follow a reliable product development based on a systems and engineering approach to minimize security risks, including those related to cybersecurity threats and vulnerabilities. This process should include systematic and continuous safety risk assessments for each vehicle into which it is integrated.

Given that vehicles with and without ADSs will be operated on public roads for a long period of time, subjects still need to consider a possible scenario where another vehicle crashes into a car and how best to protect themselves and the passengers of the vehicles in such a situation. Whether the vehicle drives or the vehicle is driven by a human, the driver and passenger protection system shall maintain its intended performance level in the event of an accident.

3.6 Security System Requirements

Manufacturers should consider incorporating information from the advanced sensing technologies required for ADS into new passenger protection systems that provide increased protection for passengers of all ages and sizes. In addition to seat configurations assessed in accordance with current standards, it is recommended to assess and consider additional countermeasures: this will protect all passengers in any alternative seating arrangement or internal configurations when the vehicle is in use [7].

Vehicles equipped with ADSs under development should ensure geometric energy absorption, compatibility of the accident with existing ADSs vehicles, delivery of goods or services or other unoccupied use scenarios, taking into account the relevant vehicle accidents compatibility and the interoperability potential of users and other vehicle types with vulnerable roads [8].

Manufacturers are not obliged to submit a voluntary self-assessment of traffic safety, nor is there any mechanism for compelling subjects to do so. For now, it is recommended to conduct these assessments prior to testing and deployment, as NHTSA does, without requiring organizations to provide information on testing or deployment.

States have a shared responsibility to reduce the number of accidents that cause death, injury and property damage to all road users in their countries.

4 Conclusion

States should use existing infrastructure to develop road networks and safety programs: driver training, testing and licensing. In addition, manufacturers should ensure pedestrian safety and law enforcement agencies should register and inspect vehicles.

Traffic management; road design and maintenance; accident prevention, investigation and recording; and emergency services [9].

Public trust and confidence in the evolution of ADSs can contribute to the development or suppression of testing and deployment of ADSs on public roads. NHTSA is committed to maintaining safety from these new and evolving technological advances that have the potential to significantly improve road safety [10].

The following security priorities are currently identified.

The Impact of "Smart Technology" on the Evolution of Ideas About the Subject Matter of Theft

Lyubov V. Lobanova, Larisa N. Larionova, and Alexey P. Rozhnov

Abstract *Purpose*: The purpose of the work is to justify the need to abandon the traditional approach to the interpretation of features characterizing the subject matters of theft by the theory of criminal law and to clarify the belonging to such subject matters of non-cash funds, including electronic, as well as individual digital financial assets. *Methodology*: The research is based on the use of knowledge from different branches of economic and legal sciences, as well as the involvement of common methods for jurisprudence: system-structural, historical-legal, logical-legal and others. *Results*: The correspondence of the statement about the material nature of the subject matter of theft to the living conditions in the information society, modern legislation and judicial practice is checked. The legitimacy of qualifying as a crime against property the embezzlement of non-cash (including electronic) funds that do not actually have the said property is emphasized. The prospects for recognizing some digital financial assets, in particular, cryptocurrencies, as the subject matters of theft are determined. *Conclusion/Recommendations*: Conclusions are formulated (1) on the necessity to abandon the outdated notion of subject matters of theft only as a thing; (2) on the uselessness of the relevant statement as an argument in the dispute over attaching digital financial assets to property; (3) on an urgent need to determine the legal status of such economic instruments in order to clarify the possibility of qualifying the illegal seizure of these subject matters as offences against property.

1 Introduction

For many decades, when characterizing the subject matter of theft, legal scholars have paid attention to its real property, implying that only objects of the material world that have physical parameters that are things can be stolen. For example, I. Ya. Foinickij emphasized: "From the physical side, property as a subject matter of abduction must be a material, bodily object of the outside world, occupying some place in space and accessible to our external feelings." [5] Approximately the same thought was expressed by V. V. Esipov, who gave the subject matter of theft three basic qualities and recognized as such things of economic importance and alien to the culprit [4].

It seems that such views of criminalists on the subject matter of theft corresponded to the notion of property developed by pre-revolutionary civilists. Thus, G. F. Shershenevich, understanding property as "a set of property, i.e. subject to monetary assessment, legal relations, in which a known person is located", at the same time stated that the right of ownership may be executed towards tangible objects, but not actions or rights [12].

At first glance, it may seem surprising that the idea of the subject matter of theft has changed little during the Soviet period of development of Russian criminal law science. And here the need to determine the material nature of the stolen object should be noted, its ability to represent any value and participate in civil circulation, belonging to someone, not the thief [15]. Only one difference is noticeable: a more prominent feature, counted as an independent property, is the social trait—labor intensity [8]. However, the physical feature still remains an integral attribute of the definition of the concept under analysis. In this regard, it can be assumed that the understanding of property crimes is determined not only by a country's belonging to a certain type of economy, but also, in part, by other factors contributing to the commodification of something that did not exist before. Scientific and technological progress has proven to be one of these factors. Russia's transition to a market economy has created prerequisites for an in-depth revision of scientific views on the subject matter of theft. Some researchers have found that the prevailing concept does not correspond to the new economic conditions of society. In this case, the materiality of the subject matter of theft is first of all questioned. "Modern economic theory," A. V. Shulga, in particular, argues. "does not connect an object of property exclusively with objects of the material world that have the "status" of things. It proceeds from the understanding of property as a relationship concerning the use of "material" and "non-material", "tangible" and "intangible" goods." [13] However, at the turn of the twentieth–twenty-first centuries such opinions were not dominant. Perceptions of theft as a thing continued to spread among criminologists [6, 9], and civilists talk about things as material substrates [11]. However, the transition of civilization from industrial to information society, which inevitably affected the Russian Federation and implies the transformation of information into a serious productive force, the formation of global information networks, as well as the overall development of

"smart technologies", including electronic payment systems, make us take a fresh look at the analyzed objective feature of theft.

2 Methodology

The methodology is based on the use of knowledge from different branches of economic and legal sciences, as well as the involvement of common methods for jurisprudence: system-structural, historical and legal, logical and legal, etc.

3 Results

The Russian Criminal Code uses a laconic formula to characterize the feature in question, which consists of two words: "property of another". To clarify it, criminal investigators are usually inclined to refer to the civil interpretation of the term "property" presented in Part 1 of the Civil Code of the Russian Federation. However, insisting on the real nature of the subject matter of theft, criminal law theorists did not immediately notice that the civil law concept of property and the concept of "thing" included in its scope had undergone significant changes in a fairly short period of time. In the first version of the latter regulatory act the legislator referred to property things, including money and securities, other property, as well as property rights. The Law No. 142-FZ of 02.07.2013 clarified the characterization of property: the legislator drew a clearer distinction between the things that, along with other property, included cash and certificated securities, and other property, including non-cash monetary means and uncertificated securities. Thus, it was emphasized that non-cash monetary means and uncertificated securities do not have physical property, but are nevertheless positioned as property. Here, one of the axioms of economic theory, according to which "money is a constant measure of the usefulness of any commodity", is clearly gaining new boundaries [1]. It is recognized as valid for any cash in circulation, whatever form it takes.

The law enforcer proved to be more pragmatic than most representatives of the criminal law doctrine, considering access to non-cash money and its illegal transfer to the current account of the perpetrator or other persons as theft, even though the money was never physically received, was not cashed. Thus, in the outdated Resolution No. 51 of the Plenum of the Supreme Court of the Russian Federation of 27.12.2007 "On judicial practice in cases of fraud, misappropriation and embezzlement", justifying this kind of legal assessment, the highest judicial authority of Russia drew attention to the emergence of the guilty party the opportunity "to dispose of the received funds at their discretion, for example, to make settlements on its own behalf or on behalf of third parties, without withdrawing funds from the account to which they were transferred as a result of fraud".

The increasing pace of the digitalization of economic relations led, among other factors, to the official recognition of electronic money. The concept of the latter was given by Federal Law No. 161-FZ of 27.06.2011 "On the national payment system".

Some time later, the Plenum of the Supreme Court of the Russian Federation reacted to it, recognizing electronic money as a type of non-cash monetary means as a subject matter of theft in its Resolution No. 48 dd. 30.11.2017 "On judicial practice in cases of fraud, misappropriation and embezzlement". This understanding of the subject matter of the crime is also extended by the Plenum to the composition of the theft.

Since then, the postulate of the material nature of the subject matter of theft has been in clear contradiction with the Criminal Code. Thus, the legislator confirmed the possibility of qualifying the theft of electronic funds under Article 158 of the Criminal Code of the Russian Federation, adding a new qualifying feature to Part 3 of this Article—theft "from a bank account, as well as in respect of electronic funds (in the absence of signs of an offence under Article 159^3 of this Code)" (Par. "g" Part 3 Article 158 in the edition of Federal Law No. 111-FZ dated 23.04.2018).

Although a little over a year has passed since then, the practice has already had experience in applying this novelty. In particular, the actions of D. V. Bolokhnov, who committed the crime under the following circumstances were qualified by the verdict of the Moscow District Court of Ryazan dated 27.02.2019. After drinking alcohol together, the convict, when he saw that his drinking companion was intoxicated and didn't understand what was happening, took out of his pocket a bag with a bank card of the mentioned person, the pin code of which was known to Bolokhnov. On the same day he went to the store and paid for the goods there, attaching the victim's bank card to the cash terminal. Similarly, he paid for the goods at other stores and cafes.

As a matter of fact, only non-cash money, including electronic money, is the subject matter of a special type of fraud under Article 159^3 of the Criminal Code "Fraud with the use of electronic means of payment". This title of the article appears in its last version, which is given to the description of the corresponding offence by the same Federal Law. However, in contrast to paragraph "d" of Part 3 of Article 158 of the Criminal Code of the Russian Federation, here the emphasis is not on the subject matter of the criminal offense, but on its method and, to some extent, the means of its commission.

In the information society, along with non-cash funds, such intangible objects as cryptocurrency, tokens, individual attributes of Internet games, etc., often united today by the notion of "digital financial assets", become very attractive for criminals.

As E. L. Sidorenko notes, the number of cases of theft of cryptocurrency from electronic wallets increases annually. In particular, an increase of more than 150% in the number of these mercenary attacks on the cryptographic currency was predicted for 2018 [14]. Obviously, in such conditions the question arises as to the admissibility of the qualification of such facts on the articles about the theft of someone else's property.

It is a thankless job for us to try to justify this possibility with the statement about the alleged tangible nature of such assets. First, the latter are even less likely to be

considered things than non-cash money. Certainly, non-cash money also does not have the spatial and temporal forms that are inherent in matter. However, in respect of monetary economic instruments it is quite appropriate to adopt a legal fiction, due to which what is not actually a thing becomes an object of law in rem. Explaining the acceptability of such a legislative approach, experts emphasize that "non-cash funds may well become cash (material and tangible) without changing their essence" [1]. But digital financial resources hardly possess such property of free convertibility. This nuance, does not seem to be taken into account by some civilists, who see the presence of an in rem property in the cryptocurrency [3. Secondly, in a situation where both civil law and criminal law provisions relating to thefts are not alien to the concept of intangible property, it is pointless to use this statement. It is much more important to emphasize the verification of the existence (absence) of other properties that the subject matter of theft should possess.

It seems that the current state of the legislation does not allow to ascertain that the subject matter of theft of all digital financial assets possesses economic and legal features. Serious doubts are expressed in this regard, in particular concerning the cryptocurrency. Such currency does not have a certain legal status in Russia today [7, 10, 14] and is also autonomous from the official funds in circulation. In this regard it is problematic to speak about the quality of the negotiability of the cryptocurrency, on which the recognition of both economic and legal attributes of the subject matter of theft depends. We believe this is right that there are courts that do not take into account the fact that the parties use cryptocurrency in their relations because these financial assets do not have the status of the object of civil rights [2]. At the same time, there are also examples to the contrary.

Thus, in the case of bankruptcy of an individual entrepreneur, the Nineteenth Arbitration Court of Appeal of Voronezh, in its decision of February 25, 2019, ordered the defendant to provide the financial manager, along with other data, information about the presence of cryptocurrency.

There are also relevant precedents in criminal cases. Thus, the subject, using his/her cell phone, under the nickname "polya2218" on the website www.LocalBitcoins.com, entered into Internet correspondence with the victim, using the nickname "Drugl" for correspondence. Through its criminal intent to steal someone else's property in correspondence with the victim, "polya2218" agreed to purchase cryptocurrency in the amount of 0.03875392 BTC (bitcoin) from this user, not intending to fulfill the obligations to pay for it. Not guessing about the criminal intentions of the counterparty, the victim evaluated this transaction in the amount of 20,000 rubles, which "polya2218", according to the agreement, should have been transferred to the victim's bank card. However, the defendant decided to send an SMS to the victim's phone instead of a real transfer of funds, fully repeating the SMS-notification from the service "Mobile Bank" of PJSC "Sberbank of Russia", hoping that the victim would accept this message for this notification from the bank about the transfer of the appropriate funds to his/her account. After receiving the SMS, the victim, being misled, believing that "polya2218" fulfilled his/her obligations to pay for the cryptocurrency, transferred cryptocurrency in the amount of 0.03875392 BTC to the bitcoin wallet under the nickname "polya2218". Having taken possession of the cryptocurrency,

the guilty went into hiding and disposed of the stolen at his discretion. The verdict of the Oktyabrsky district court of Tambov of 15.02.2019 qualified the above actions under Part 2 of Article 159 of the Criminal Code.

While recognizing such precedents as an example of the application of criminal law by analogy prohibited by the Criminal Code of the Russian Federation, we note that at the same time they demonstrate the need for a speedy resolution of the problem of determining the legal status of virtual currency. In order to create a favorable investment climate in Russia, it is more profitable for the state to take control of the turnover of digital financial assets rather than ban it at all. By means of bans, it is hardly possible to restore confidence in traditional financial instruments. It is no coincidence that the relevant task has been presented as one of the key points in the national program "Digital Russia".

One of the first steps in this direction has already been taken. Thus, from 01.10.2019 amendments and additions to the Civil Code of the Russian Federation contained in the Federal Law of 18.03.2019 N 34-FZ will come into force. The objects of civil rights will now be treated as a type of property rights, i.e. "the rights referred to as such in the law are mandatory and other rights, the content and conditions for the implementation of which are determined in accordance with the rules of the information system that meets the criteria established by law".

It should be noted, however, that these innovations do not prejudge the question of the legal status of cryptographic currency, but are the starting point for solving this problem at the level of a specialized regulatory act. Apparently, it is here that we have to determine whether the virtual currency contains a claim right, and to whom it is addressed, and therefore, what is the mechanism of its protection. Unfortunately, the transformation of the relevant draft law into a legislative act was somewhat delayed.

4 Conclusion/Recommendation

The judgment on the material nature of the subject matter of theft, which is common in the criminal law doctrine, does not correspond to the realities of today, neither the current state of civil and criminal law, nor the emerging law enforcement practice. This is clearly evidenced by the official recognition of the status of other (i.e. different from things) property for non-cash, including electronic money, the construction of the elements of crime, in which they are explicitly designated or implied as the subject matter of theft, as well as the need for the relevant criminal law norms by practitioners. In order not to mislead the addressees of criminal law, it must overcome the emerging backlog of social development as soon as possible.

Attempts to substantiate the possibility of qualification under chapters of Article 21 of the Criminal Code of the Russian Federation for the illegal acquisition of digital financial assets by means of the thesis about the alleged material nature of the latter seem unpromising. It is much more important to focus on verifying that such economic instruments have other properties that are indeed inherent to the subject matter of theft. We have to state, however, that the current state of the law does not

allow us to say with certainty that all digital financial assets have the appropriate qualities. Thus, the uncertainty of the legal status of the cryptographic currency, its absolute autonomy from the money in circulation give rise to great doubt that the named digital financial resource has the necessary negotiability for property. The available jurisprudence on the qualification of thefts of cryptocurrency under the articles on crimes against property in this regard should be seen as examples of the application of criminal law by analogy. At the same time, such precedents are clear evidence of the need to resolve the legal status of virtual currency. Judging by the growing pace of digitalization of the economy, without such a legislative step it is impossible to ensure the recovery of the investment climate. The assignment of digital rights to objects of civil rights, laid down in the Federal Law of 18.03.2019, only creates some prerequisites for this, the implementation of this task, set by the state, strongly requires legislative regulation of the issue of assigning digital rights to certain digital financial assets, including cryptocurrencies. Hopefully, it will not be too late to turn the draft law on digital financial assets into a piece of legislation that must find an acceptable solution to the problem.

The Application of Artificial Intelligence Technologies in Telecommunications

Sergey S. Golubev, Aleksandr I. Ivanus, Dina A. Aybosynova, and Viktor A. Chinaev

Abstract ***Purpose***: The purpose o The Application of Artificial Intelligence Technologies in Telecommunications Sergey Golubev, Aleksandr Ivanus, Dina Aybosynova and Viktor Chinaev from the study is to estimate the trend of the uncertainty level of the telecommunications services market and to establish its relationship with the application of artificial intelligence technologies in telecommunications, as well as to reveal current problems of the telecommunications services market and find solutions to them in the context of the introduction of digital technologies. ***Design/methodology/approach***: The authors put forward the hypothesis that the problems of telecommunication companies can be solved as long as new technologies of artificial intelligence will be introduced. To this end, the authors employed the methods of analyzing the publications on artificial intelligence and measuring the level of uncertainty on the telecommunications services market, as well as statistical analysis, mathematical modeling and other methods of scientific research. ***Findings***: The authors found out that available methods of servicing, monitoring, and forecasting telecommunication companies need to be automated. They offered a method to measure the level of uncertainty on the telecommunications services market and identified the upward trend of the uncertainty indicator. Relying on this trend and the successful application of artificial intelligence in many IT technologies, the authors came to the conclusion that the introduction of artificial intelligence in telecommunication services is expedient and well-timed. It has been justified that the expected

effect can be as high as in other areas. The authors outlined the segments of telecommunication services that are the most economically efficient for digital technologies. ***Uniqueness/value***: The research is unique because it establishes the interdependence between the uncertainty of the telecommunications services market and the penetration of artificial intelligence technologies. The authors proposed a new methodology for assessing the level of uncertainty in the telecommunications services market. The value of the research lies in that the paper reveals the modern problems of the telecommunication companies and justifies the feasibility of these problems under the methods of AI introduction using the examples of companies providing information services.

Keywords Telecommunications · Information technology · Artificial intelligence · Risks in terms of uncertainty

JEL Classification L86 · L81 · L96 · G32 · N7

1 Introduction

Today it is hard to imagine human life without telecommunication services. The Internet, TV, and radio play an important role for people, influence their quality of life, provides the required information and multimedia. Therewith, communication channels serving a large number of subscribers are overloaded due to the great demand for services. This situation decreases efficiency and slows down the pace of the company's development.

The telecommunications are associated not only with the development of telecommunication technologies but also with other related technologies, like information ones. They are growing faster and faster every year. Nevertheless, the growth brings market risks and uncertainty, which can dramatically cut rapid the market share among competitors [1].

In this regard, arises a need to develop other directions of telecommunications and change the operation methods and tools in telecommunication companies. Therefore, today the question of the urgent introduction of artificial intelligence in telecommunication companies is pretty acute. AI will automate many business processes of companies and thereby help to avoid overload of communication channels.

2 Materials and Method

The main objective of the research is to carry out a statistical analysis of the risk zone in the context of services market uncertainty and the identification of the regularities between the current problems of telecommunication management and maintenance systems and the subsequent development of new design principles.

For identification of the risk zone in the context of uncertainty, we conducted mathematical calculations based on annual reports of companies for recent years [2].

Revealing the current problems of telecommunication management and maintenance systems required the methods of theoretical analysis and synthesis. This made it possible to present the current management system and investigate phenomena and processes in the most complex combinations, as well as outline the most critical features and properties, links, and relationships, discover patterns of their development in terms of risk and uncertainty. The analytical work was followed by the synthesis and integration of findings in a common system [3].

The research background was academic papers by domestic and foreign scientists and regulatory documents on the development of information management systems, as well as the capabilities of new digital technologies in solving the related problems.

3 Findings

The technological changes connected with the introduction of digital technologies and artificial intelligence affect the performance of many companies, and especially telecommunication ones with the fast development pace of high-speed data transfer technologies. This factor leads to greater demand for high-quality and diverse textual and visual information that companies seek to convey to their customers. In the context of the rapid development of information technologies, a zone of risks and uncertainty is formed. Thereby the need for more accurate projection has become higher.

Recently, the telecommunications services market has been marked by the rapid growth of mobile Internet users, which in turn allow telecommunication companies to increase their profit from the provision of this service.

Therefore, it is advisable to investigate the dependence of economic performance indicators of mobile providers for recent years on their revenue and prime cost for calculations.

The entropy value N was selected as a measure of uncertainty. The value of entropy describes the uncertainty of the system state and shows its relationship with the parameters of the telecommunication company structure, which depends on the quality of management.

In the concept suggested by the authors, N is calculated using the Verhulst equation. This equation first appeared in the time of an analysis of the population growth model [4].

In this paper, the equation is as follows:

$$d\mathrm{H}/d\mathrm{t} = \mathrm{Pcost} \times H - \mathrm{Rev} \times H2$$

where Pcost is the prime cost of the services provided in the telecommunication sector, which makes up the final cost of the service, and Rev is the revenue from these services.

The indicators Pcost and Rev have been chosen because they are illustrative of the essence and peculiar features of telecommunication companies. The matter is that the value Pcost displays the costs for the provision of services, and Rev—its financial result. Therefore, Pcost-Rev ratio predetermines both the quality of services provided and the level of uncertainty of the company's performance on the telecommunication market. If Pcost is increasing and Rev is constant, we can talk about the low-quality management of telecommunication companies. Besides, there is a clear correlation between low-quality management and high uncertainty in the telecommunications market.

The value of the entropy indicator N is interconnected with growing uncertainty therefore it can be chosen as a measure of uncertainty.

These instances are not new in the academic literature, they are practically proven and confirmed.

This process is exhibited to the full extent in the above Verhulst equation. Let's adjust this equation to a discrete form.

The ratio can be approximated as follows:

$$dH = Hi + 1 - Hi$$

If dt is roughly equal to 1 year, then we get:

$$Hi + 1 = Hi + \text{Pcost}\, i \times Hi - \text{Revi} \times Hi^2$$

This equation can be applied to assess the trend of system state uncertainty under the influence of two competing factors (costs for the provision of services Pcost and the revenue Rev).

Data assets on the prime cost and revenue of leading telecommunication companies are presented in Table 1.

Let's calculate the increment of these indicators and estimate Hn (Table 2).

A chart of uncertainty levels for each company is presented in Fig. 1.

Let us note that in all companies under consideration the uncertainty indicator keeps on growing. Besides, one cannot but point out a sharp increase as for MTS in 2012 and a decline as for Beeline in 2014.

Thus, we can conclude that telecommunications companies operate in the zone of constant risks.

Along with that, we observe the following relationship: the more complex the structure of company management and the arrangement of business processes and the more branched and diverse the external contacts of the company, the higher the risks common to telecommunication companies. Flawed management of a telecommunications company's performance and tardy exchange of information between salespoints and the head office prevent prompt delivery of the data, as well as lower the speed and quality of managers' analytical work. This situation causes losses in telecommunication companies which in turn challenge the successful performance of the company. These facts indicate that business processes need to be improved

Table 1 Prime cost and revenue of megafon, beeline, and MTS over 2009–2018 for calculation of uncertainty level

C.O	Megafon		Beeline		MTS	
Pcost/Rev	Pcost	Rev	Pcost	Rev	Pcost	Rev
2009	136,594	181,883	163,070	200,391	130,998	197,655
2010	166,343	215,515	187,013	210,128	150,185	216,130
2011	219,029	252,608	215,067	261,098	266,276	348,571
2012	208,454	272,336	226,180	280,300	284,446	378,240

through the introduction of artificial intelligence systems. The application of this technology will allow predicting and assessing likely hazards, investigating their impact on the profit of telecommunication companies and help the company's management to take appropriate preventive measures.

The second problem of the telecommunication market is the huge scope of tasks performed by the company's employees which overloads the staff and slows down the development of telecommunication companies. For example, the number of mobile subscribers in Russia for the first half of 2019 rose by 1.9 million people, by 7 million—as of the end of 2018 up to 260.6 million at the end of June 2019 [5]. Presently, most subscriber servicing is charged with the company's staff therefore the workload can be reduced only if the company expands the staff that will knock a hole in the budget.

According to the annual reports of companies for 2018, MTS leads 65 thousand employees and 105 million subscribers; MegaFon has 40 thousand employees and 77 million subscribers; Beeline closes the top-three with 23 thousand employees and 55 million subscribers. The total number of employees is 128 thousand, 30% of them belong to top management and service employees of the company itself. There remain 90 thousand employees for 237 million subscribers [6].

Statistical data show that every 25 mobile subscribers make daily calls to the support service. Let's divide the number of subscribers by the average number of calls to estimate the average number of calls in support service N of the mobile provider. For the three leading telecommunication companies, the average daily number of calls amounts to 105 thousand. This is the daily number of calls per 90 thousand employees, i.e. 1 person is processing 100 calls per day [7].

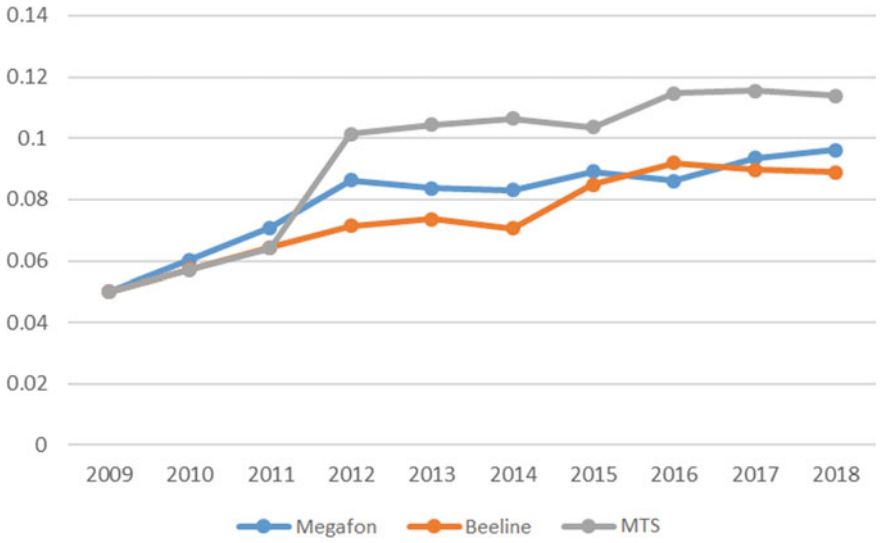

Fig. 1 The level of uncertainty for megafon, beeline, MTS over 2009-2018

Conventional methods of servicing involve a telephone or e-mail communication to record and solve the problem. The call depends on circumstances and lasts 5–15 min on average. The service personnel is not enough due to a large number of subscribers, and therefore the current servicing system requires the new methods.

Many companies have long demonstrated interest in artificial intelligence and have invested heavily in AI-based information systems. Mobile providers automate manual processes related to subscriber servicing. New development trends that are responsible for the design of AI products and the integration of technologies into available and currently developed services appear. Companies are intending to invest hundreds of millions of rubles annually in artificial intelligence developments. The first solutions worked out by company divisions involve the development of platforms for chatbots, virtual assistants and AI-based telemedicine service. Some companies already have chatbots launched in Telegram [8].

First of all, the application of artificial intelligence technologies makes it possible to take the advantages given in Fig. 2.

The introduction of artificial intelligence algorithms into operating information systems allows for the dramatic transformation of financial performance projection and analysis of services market conditions. For example, artificial intelligence algorithms allow dividing information into subclasses and categories, thereby getting more accurate and particularized information on customers and sales.

These software algorithms based on neural self-learning networks can identify deficiencies and find the most suitable solutions in uncertainty. Thus, companies have firm representation in the services market, consequently, the risks are reduced to a minimum.

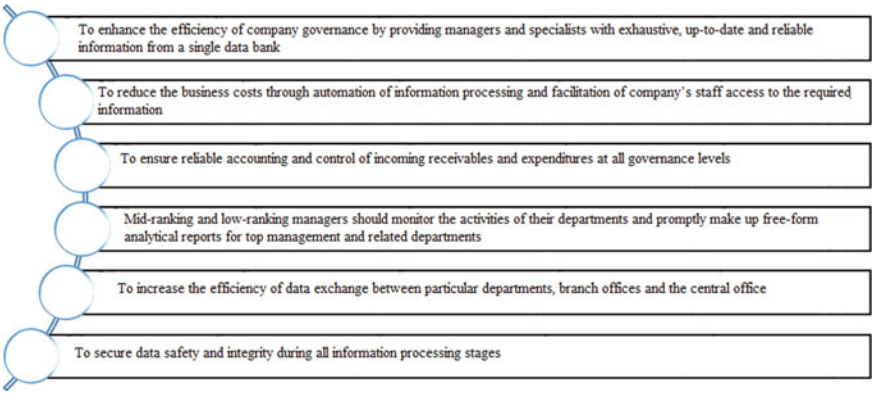

Fig. 2 Advantages from the application of AI information technologies

For example, thanks to the processing of information with the help of big-data artificial intelligence the likelihood of falling customer's interests in marketing sampling are much higher. As a result, a larger share of subscribers will order the services of the companies applying AI algorithms. AI-based systems are already used for the automation of subscriber servicing of cellular. They are still far from perfect, but highly automated facilitating the work of mobile providers [9].

Many companies have started to develop intelligent assistants to help the employee quickly find information in the knowledge base, as well as choose ready answer options. On average, this saves 30% of the service provider's time spent on search in the knowledge base [10].

Virtual assistants are capable of interacting with a human voice under preset algorithms and answering the most common questions of customers. For example, customers who have been waiting for an operator for a long time (over 5 min) can immediately address the virtual assistant, thereby the company automates the call. Now, these assistants can process 300 thousand calls per day and answer questions concerning expenses, balance, traffic balance, Internet connection, access to service, the Internet, pledge payment, mobile subscriptions, international roaming. This function alleviates the activity of mobile providers and automates 65% of operations [11].

Besides, virtual assistants are used in active sales of services. This can save about 60% of the money spent on salaries [12].

Artificial intelligence can also be useful in voice biometrics. At the same time, accurate recognition of the voice, as well as its changes became possible. This technology can be used for data identification in call centers, for example by passport. The survey showed that 72% of customers are ready to pass identification and 27% concern about their voice change. The technology saves to a great extent the time spent by employees on identification [13].

Chatbots are growing more popular in text-based service channels. This tool provides customers with basic information, thereby solving the problem of excessive

calls and automating servicing. Today, this kind of a chatbot can automate 70% of incoming applications [14].

Voice analytical tools are of particular interest. They allow monitoring the staff activity by scripts, process customer's thanks, search for negative dialogs, as well as successful sales experience. The tool helps to search for typical customer complaints, rough answers, illiterate and babbled speech, analysis of conversation topics and duration of silent broadcasts, as well as identify customers intending to reject the company's services.

When using AI-based information systems, companies enhance automation, which helps to improve the quality of service and decline the number of customer's complaints. This will make the company's image more attractive to customers and will contribute to the growth of sales. Also, there is an opportunity to expand the application of artificial intelligence for HR services [15].

The importance of artificial intelligence is approved by the Strategy for AI Development in Russia until 2030. Another sector of AI telecommunication in high trend is the Internet of Things, based on smart network-connected devices, which number doubles in the world. By 2020, it expected that their number will soar to 20 billion connected devices [16].

The analysis showed Russia intensively uses artificial intelligence technologies, 34% of them are related to image and video recognition, 19% are associated with the text and voice recognition, 15% help to make managerial decisions, and 12% carry out data analysis [17].

It is projected that the artificial intelligence market in advertising, retail, and finance to grow by at least 60% annually due to the expanded use of machine learning technologies, as well as voice recognition tools. By 2022, its volume will reach about $16 billion [18].

Gartner forecasts evidence that about 40% of customer communication by 2020 will be based on NN-processed data (neural networks). It should also be noted that the USA allocates annually $200 million of budgetary funds for AI research [19].

Russia is launching many new projects on the introduction of artificial intelligence in operating telecommunication systems. The private investors heavily inject money in Big Data and AI start-ups. This investment market in Russia alone can amount to 15 billion rubles per year.

Also, Russia is working out some standards with minimum requirements for AI developments. The technical committee established under the Russian company "RVK" cooperates with foreign counterparts. Russian standards will take into consideration the ISO standards [20].

After the introduction of artificial intelligence in customer services, the number of complaints has reduced, the quality of service has become higher, the number of customers addressing expensive service companies has declined, the automation and the company's attractiveness has enhanced.

Finally, we can say that the telecommunications industry is a promising area for the further development and application of AI technologies in Russia. The largest telecom companies are proving this statement with their own example.

4 Conclusion

The analysis revealed a strong relationship between the level of uncertainty on the telecommunication market and the growing feasibility of AI introduction by telecommunication companies.

Neural networks are often used when entrenching artificial intelligence in various systems, including telecommunication ones. They allow solving many intellectual problems, namely replacing projection with recognition, simulating the response of the telecommunications services market to occurring risks and external effects. This is especially important in the event of similar recurrent risks to the operation of telecommunications companies.

Relying on AI application practices in various fields of digital technology introduction, we concluded that the application of artificial intelligence in the telecommunication sector is expedient and well-timed. The companies will get the economic and social effect from the introduction of artificial intelligence as high as in other AI fields considered in the article. Along with that, we want to note that artificial intelligence will never replace staff in making managerial decisions. Artificial intelligence technologies are widely used for integration of statistical data, moreover, the criterion for data collection is set by a man but no by artificial intelligence. Although neural networks are adaptive in nature and are imitating the human course of problem-solving, they cannot choose the criteria for a solution in a critical situation.

We have outlined the telecommunication services and telecommunication company management areas that are the most expedient for the introduction of artificial intelligence. The above involves the work of call center operators on customer relations, development of various chatbots answering customer questions, retaining customers and enhancing their loyalty in targeted marketing, the analytical operations by sales managers, issuing documents and inquiries for customers and management staff. Artificial intelligence can also be used in HR-services.

We have justified that today artificial intelligence positively proved itself when managing telecommunication enterprises working under risks and external uncertainty. In this regard, we can draw a conclusion that on the necessity of introducing AI in telecommunication companies and pursuing further research in this field. Besides, it is remarked that artificial intelligence has great prospects in the management of complex economic processes under high-tech enterprise risks.

Economic Digitalization: Contradictions and Prospects

Andrey E. Sychev, Elena V. Zaytseva, and Pavel S. Tolkachyov

Abstract At the present stage, digital (information) technologies start playing an ever-increasing role both in the particular national economy and the entire world economy. This is also the case of Russia. Within the market economy, the information system due to the rapid exchange of information between economic agents (from small businesses to large corporations) helps quickly take appropriate decisions when entering into economic transactions. It is clear that the sophistication of the Russian information system will dramatically contribute to all business processes, as well as enhance the quality of the national economy administration (including economic security). Digitalization is designed to serve as an instrument for the advancement of state regulation of the economy.

Keywords Economy · National economy · Economic globalization · Digitalization · Digital economy · State regulation of the economy

JEL Classification O15 · O33

1 Introduction

Nowadays, digitalization is becoming a major driver of world economic growth. The fast-paced progress in the field of information technology was the lever that passed from the theory of globalization to its practical implementation. Thanks to digitalization, a market economy in terms of the world economy has gained the

hope for crisis-free development. In the event of its successful spreading, the world information system could reconcile earlier inconsistent economic principles: the individual freedom of the entrepreneur (and the employee) and the harmony of the entire global economic process.

Digitalization proposes to abandon all methods of state market regulation. In the theoretical model of the information space, the external compulsion of market counterparties to make appropriate decisions makes no sense, because they are able to almost instantly coordinate their behavior.

The outreach program of the global information system ushers the dawning of an economic prosperity age and near the establishment of heaven on earth. However, the real events related to the spread of information technology evidence the opposite. The contradictions do not disappear, but persist and take new forms. In this respect, the entire world and Russian economic (and political) practice of the start of the new millennium is eloquent [1].

There is no doubt that digitalization can bring the economy a lot of advantages. Nevertheless, one should clearly see all its pros and cons as well as understand the place of the information system in the economic process (both national and global) and make a distinction between the nature and forms of this phenomenon. The theory of the information economy developed by Russian scientists today must make precise recommendations to state authorities for the successful pursuance of the national economic policy in the field of information technology. This is a common topical scientific and technical task of the Russian intelligent community.

2 The State Policy of Russia in the Field of Information Technology

In 2017, President V. V. Putin issues a decree on the adoption of "Strategy for the Development of the Information Society (for 2017–2030)." The program is intended to found the Russian information space, to develop information technologies and information competitiveness at the international level. The same year, the Government Resolution approved the national program "Digital Economy of the Russian Federation". Later (in 2019), it was transformed into the national project "Digital Economy of the Russian Federation".

In his Address to the Federal Assembly on March 1, 2018, the President of Russia V. V. Putin has stated economic digitalization as one of the national priorities. Besides, the President emphasized that **the national information system** that would be technologically protected from foreign digital platforms should be designed. V. V. Putin specified that it's not about the isolation of the Russian information system, but of its independent existence when communicating with the global one. One of the primary tasks assigned by the President of Russia to the developers of the national information system is an enhancement of the country's security (along with the economic one).

A further view of the goals and objectives of the national information system to be developed in Russia President was presented by V. V. Putin in his Address to the Federal Assembly in 2019 (February 20, 2019). Therein he drew up a four-point development program of this field:

(1) to make Russia one the leading countries in the information space;
(2) to develop high-speed Internet across the country;
(3) to digitalize the document management system between government agencies;
(4) to employ the national information system as an anti-corruption tool.

Further developing the topic of the betterment of the state policy in the field of digitalization, the President of Russia in his Address to the Federal Assembly on January 15, 2020, said that "…Today, the technologies drastically change, and we should develop our technologies and standards in the fields that are important for our future. Above all, we are talking about artificial intelligence, genetics, new materials, energy sources, digital technologies… In this regard, I deem it is reasonable to speed up the digital transformation of the real sector of the economy. Along with that, it's necessary to lay down the requirement that national projects be implemented mainly based on domestic software products".

New Chairman of the Russian Government M. V. Mishustin making his speech on January 16, 2020, before the deputies of the State Duma highlighted nine challenges to be dealt with the Russian government:

- the first one is taking care of the family and children;
- the second task is improving the management quality;
- the third one is raising the well-being of the population;
- the fourth challenge is making the business space more favorable;
- the fifth task is using the resources at the government's disposal in an efficient way;
- the sixth one is promoting the digitalization of the real sector of the economy;
- the seventh challenge is continuing the development of the agricultural sector;
- the eighth task is focusing on the transport, especially highways;
- and the ninth one is launching a new investment cycle.

In his speech, M. V. Mishustin admitted that the digitalization of the real sector of the economy is not perfect and we need a real breakthrough here. According to M. V. Mishustin, the government will carry out digitalization within the national project "Digital Economy" and actively put domestic developments into practice.

The full-fledged national information system is designed to provide the collection and processing of information on all levels of the national economy: macro (national economy as a single whole), meso (national system of sectors and regions), and micro (national system of enterprises and economic organizations). Look at these structural levels in brief.

3 The Organizational Framework of the National Economy

Any national economy is a complex hierarchical system of three coordinated levels: macro, meso, and micro [2].

At the macro level, the national economy (macrostructure) acts as a single whole, as a special economic unit within the world economy. It performs two main functions: social and production. The social one is aimed at direct satisfaction of the society's material needs. It is expressed in the output and consumption of goods and related services. One of its key indicators is the standard of living. The production function is characterized by the overall output [gross domestic product (GDP)], the resources of the production means, the availability of manpower, labor productivity, and other performances. The functioning of the whole national economy is called socio-economic [3–11].

In an essential sense of the word, the macrostructure is governed by society and all its members. However, the practical delivery of this universal linkage requires a centralized form. From its surrounding, the society chooses a nerve center (in the person of the state), which, entering into communication with each individual, provides the coordinated motion of society as a whole (including the execution of common economic tasks).

Both the next structures of the national economy (meso and micro) are located within the macrostructure and inherit its basic properties.

The mesostructured treated in economic terms has two main forms (sectoral and regional). Its actors are the sectors (including cross-sectoral complexes) and regions represented by the appropriate governing agencies. The non-economic components of the mesostructure include the so-called public areas such as culture, science, education, healthcare, defense, civil security, and some others. They are surely connected with the economy, however, they have own content and tackle different (intellectual and spiritual-moral) tasks.

Even though all actors of the meso-level in one way or another are controlled by the state, they have a certain freedom and independence. Within bounds, they are eligible to enter into direct relations with each other by escaping the instructions of the state center. For example, the sectoral structure is changing mainly due to scientific and technological progress. And changes in the regional structure may be associated with the behavior of historical and cultural-national factors.

Due to hard-predictable changes within the mesostructure, the requirements for state impacts on its components are very high, which corresponds to the art of statecraft. Maintenance of a well-balanced state of the entire meso-level is the priority state task.

The third (the lowest hierarchical) level of the organizational structure is its microstructure (or, in other words, the micro-level). This structure is formed within the first two levels and distinguished by the most complex system of involved parties. Its direct participants are legal entities (relatively independent economic enterprises and organizations). The organizations directly communicate both with each other and with the state (state center), and regions, and industries (meso-level actors).

Within the boundaries of the microstructure exist a market economy in its entirety. It is important to understand that only here (that is, at the micro-level of the national economy) there are full-fledged market relations (certainly provided that established institutional rules are observed). They are free if private ownership of the production means is granted.

The stable and (that's especially important!) well-balanced operation of the national market economy hinges in many respects on the effectiveness of state measures. High importance here is also attached to the state of relations between national market agents and industries/regions. It is distinct that state regulation of the national market system cannot be compulsory, otherwise, it would disrupt the critical factors of development such as personal freedom and private initiative. But, on the other hand, the state cannot be eliminated by the market and play the role of "night watchman" as some used to say in early bourgeois English society. The state cannot allow anarchy in the national market. Therefore, the state regulation of a market economy is weighty and at the same time challenging task posed before public authorities.

There is no doubt that the unfolding digitalization can dramatically increase the performance of the Russian system of state economic regulation.

4 Information Technology at the Structural Levels of the Economy

From the standpoint of the organizational structure of the national economy, current digitalization (not only in Russia, but in the whole world) is unfolded not "from the top" (macro-level), but "from the bottom" (microstructure). It is a "revolution from the bottom" although logically it should be reverse (from top to bottom), i.e. from the general (national) to the particular (private market agents).

However, scientific and technological progress decided in its own way. First, the advent of the Internet and then appeared a digital market economic system and a digital market economic space. Its driving force has become a new scientific and technical field called the "digitalization".

The first successes of digitalization have brought economic euphoria. It seemed to many people that the digital economy is capable, if not to the full extent, but replace the state in many respects.

In particular, these ideas were expressed at the Gaidar Forum held at the RANEPA (January 15–16, 2020). In the panel discussion called "Trust as a factor and a tool of economic development", digital platforms were recognized as the main driver of the Russian economy. As an example, Moscow has become the world leader in the distribution of car-sharing thanks to digitalization (in 2019, Moscow expanded this market sixfold).

However, the national information system can partly solve the task of self-regulation of the economy. In this case, this relates only to the micro-level (the

location of the entire space of a market economy) where function private economic entities (business organizations). Nevertheless, even at the micro-level of the national economy, market relations are not exercised in their pure form, because here there both private companies and state enterprises. The economic relations of state enterprises cannot be called full-fledged market relations. All enterprises of the defense sector, large research centers, and a wide range of similar actors work in terms of the state order and respective state programs. All of them are continuously controlled by the state. And digitalization here can fulfill only a partial role of self-regulator.

Indeed, the national information system should comprise all levels of the national economy (macro, meso, and micro). Its main objectives have to be the collection and processing of economic information incoming from all levels of the national economy. The key advantages will be the completeness and processing speed of data. The result should be sent in an intelligible form to the appropriate bodies of the economic administration: (1) public agencies (macro-level), (2) sectoral and regional government bodies (meso-level) and (3) heads of enterprises and organizations (micro-level).

It stands to reason that the digital economy unfolded at the micro-level in no way can sustain the efficient socio-economic development of the entire national economy.

Only the whole society (in the person of the state) can successfully solve higher economic problems, which is the exclusive power of the macro level.

Complex regional and sector-specific tasks can be tackled only at the meso-level through appropriate regional and sectoral government bodies. As for the simple market situations (micro-level), digitalization is capable of performing both information and governance functions.

5 Conclusion

Summing up the above stated, we can say that the development of digitalization is pretty important for Russian society. However, the goals, objectives, and methods of this development should be substantially revised. One should recognize the application of an integrated approach to the current state policy in the field of information technology (digitalization). It is essential to acknowledge that digitalization has to cover all levels of the national economic system (macro, meso, and micro) and provide accurate and up-to-date information to each level that would allow the chiefs to impartially and quickly assess the current economic situation and make the right decisions.

Digital Economy Development as an Important Factor for the Country's Economic Growth

Shakizada U. Niyazbekova, Luiza P. Moldashbayeva, Bakhytzhamal A. Zhumatayeva, Tatiana M. Mezentseva, and Larisa V. Shirshova

Abstract The development of the digital economy can stimulate the country's economic growth, be an attractive factor for research and investors, and the development of human capital. In the digital's context economy, requirements for components of human capital and mechanisms for its reproduction are changing. The measurement of the indicator is rather an assessment of the skills needed to take advantage of the opportunities offered by digital technologies. The speed of breakthroughs in digitalization has no historical precedent. The development and formation of the current digital economy undermine traditional ideas about businesses' structure, how they operate, and how consumers receive services, information, and goods. The digital economy is a multi-faceted, revolutionary and important phenomenon in the modern world, in which globalization is expressed in double-digit rates of annual growth in the world economy. The relevance is that the development of the digital economy in countries is considered a key factor of economic growth in a competitive environment. *Results*: 1. Analysis of the development in the digital economy revealed problems: the low purchasing power of the population, undeveloped logistics channels. 2. Digitalization in the economy is a necessary investment and developing

1 Introduction

The country's competitiveness in the global market depends on the level of development of the digital economy. Digitalization is a new driver of economic growth that can improve the efficiency and productivity of business processes. The digital economy has a broad meaning. Markets and industries in the digital economy mean traditional areas of activity where suppliers and consumers interact directly. The revolutionary business models generated by digital technologies can be classified by the main type of value they provide to the customer: the value of cost, interaction, and the platform.

2 Background and Methodology

In the research system analysis, various methods of information processing, and comparative and system analysis were used.

3 Discussion and Results

In Russia, the studied phenomenon is revealed In the strategy for the development of the information society, approved in May 2017 [1]. The reasons for the digital economy's appearance: request for a technological driver of an innovative factor of production-information, caused by a slowdown in the global rate of productivity growth of traditional factors.

The key technologies of the digital economy are listed below.

1. Big Data. One of the solutions is Big Data technology, which includes various technologies for collecting, processing, and storing arrays. The term "big data" refers to the entire process through which passes information for real use. This means that it covers the entire lifecycle: data collection, analysis, and implementation [2].

Earlier, Big Data was used mostly by large businesses, not only because their wide range of services that required more accurate data but also because they were the

only ones who could afford the technology and channels used to collect and analyze information. Like any other process in the business world, Big Data has developed at an incredibly fast pace. The best example of this is big data in the cloud. Today, even small businesses can take advantage of big data because they no longer need complex installations and expensive data experts, everything needed is available remotely. Various forms of data are collected and combined to help businesses draw analogies between datasets, come up with actionable ideas, and help them make decisions [3–6].

An endless stream of information is useful for business, but it can also be a challenge to get relevant information from such a large pool of data. Another problem is getting the correct information. Even with these challenges, we can't deny big data business and growth opportunities.

The basic direction of big data in business is called business analytics. It is used for the effective promotion of a company's product or service in target markets by analyzing a huge amount of data about potential customers.

2. Neurotechnology is a set of technologies based on the principles of functioning of the nervous system, which was made for the creation of globally competitive technologies in the world market, necessary for the development of new markets, goods, services, including that aimed at increasing the duration and quality of life. Artificial intelligence includes a number of algorithms and software systems, the distinctive feature is that they can solve some problems just as a human who's thinking about their solution.

There are two directions of AI development. The first one includes solving problems connected with the approximation of specialized AI systems to human capabilities and their integration, which is realized by human nature. The second direction is the creation of artificial intelligence; this is the integration of already created AI systems into a single network that able to solve the problems of humanity [7–9].

The advantages of using artificial intelligence—which is already shown today—are improving the customer experience, the quality of products and services, attracting new customers, optimizing business processes, advancement of business communications, reducing costs, increasing revenue, developing new products and services, and entering new markets [10–13].

3. Blockchain. A blockchain is a bunch of immutable data records with timestamps that are managed by a cluster of computers that don't belong to any entity. Each of these data blocks is secured and linked to each other using cryptographic encryption principles. A group of people or a person known by the pseudonym Satoshi Nakamoto made this ingenious invention.

The key advantage of the technology is its decentralized block distribution system. Because it is a general and immutable register, the information in it's open to everyone. Therefore, everything that is built on the Blockchain is transparent, and all participants are responsible for their actions.

Blockchain does not incur transaction outlays—it is a simple but original way to transfer information from A to B in a fully automated and secure way. One side of the transaction initiates the process by creating a block. And the block has been verified by thousands, possibly millions, of computers distributed over the network.

The verified block is added to the chain that is kept in the network, creating not just a unique record, but a unique record with a unique history. Falsifying one record will mean falsifying the entire chain in millions of cases. This is almost impossible. Bitcoin uses this model for monetary transactions, but it can be used in many other ways. Initially, the technology was developed for the digital currency Bitcoin, but today the technical community has found other ways to use this technology.

4. Wireless communication technology. Wireless communication technology makes it possible to communicate between two or more objects at any distance without using wires or cables of any kind.

It includes communication using radio frequencies and infrared waves. Stationary wireless technology includes desktop computers that connect to the Internet using wireless local area networks. Wireless phones, laptops, and handhelds with wireless connections categorized as portable, and cell phones are the most common example of mobile wireless technology. Wireless Internet access is expected to exceed wired access in the next few years, and the prospects for the future are impressive.

The scale of upcoming changes is amazing, and the potential of transparent digital technologies is unique. It is necessary to study, master and implement technologies everywhere. The development of the digital economy leads us to its tools, which are needed to increase competitiveness in the modern world, where digital technology is just the ability to capture, store, analyze and process huge amounts of data and information, which has increased the capacity of the decision-maker. Digital technology has become the main factor in contributing to various production, service processes and an important component of business processes. The residual effect is that increased use of digital technologies by audit companies has led to increased budgets, successes, and failures, and raised awareness of the need for control.

5. The technology will significantly affect the management process. And all of that affects the achievement of goal control.

6. Technology will affect the audit profession in terms of how the audit is performed (collection, analysis of information, control issues) and the knowledge needed to conclude operational or system effectiveness, efficiency and integrity, and the integrity of reporting. Initially, the impact was focused on the work with the modified processing environment. As the need for auditors with specialized technological skills grew, so did the profession. Integrity, reliability, and accuracy of information: are important in today's global business environment.

4 Conclusions

Thus, the growth of the digital content market subsequently provides an incentive to increase the speed of data transfer, the appearance of users and getting used to paying for content, and an incentive to expand the number of devices. The digital economy market in Russia can be described as developing. The digital society is at the center of the digital economy, so the speed at which everything moves, affected distance, and the measure of their superiority differ from previous. The digital economy has

an importance in the information infrastructure and innovation, the characteristics of the digital economy and the emergence of a revolution in information infrastructure. Digital transformation in the economy requires huge investments and organizational changes.

To become competitive and relevant to society, traditional grocery stores and boutiques must use digital technologies. In this way, they will be able to scale up their operations using models that include financial technologies. Digital technology is changing and developing too fast. More efforts should be made to optimize the management of the digital economy development process, which includes the development of monitoring and analytical tools that allow estimating the effectiveness of the strategy's implementation.

It is necessary to develop a mechanism of continuous interaction and active participation of all key economic stakeholders in the transition to the digital economy, and mechanisms for continuous and constant coordination at all governmental levels. Today, companies in a dynamic environment have strict requirements for digital technologies. The program design is complex, and management is very difficult. Companies crucially depend on the timely, accurate information flow. A good way to estimate how strict the network requirements are is to analyze it in terms of service quality.

Industry Specifics and Prospects for Business Application of Digital Technologies

Using the Digitalization Experience of Small Enterprises of the Tourism and Hospitality Sector in Germany for Development of the Tourism Infrastructure in Russia

Alexey D. Chudnovskiy, Olga R. Tsabolova, and Marina A. Zhukova

Abstract This study is aimed at exploring the experience of arranging the digitalization of small accommodation facilities in Germany for the development of tourism and hospitality infrastructure in Russian regions. The article deals with the peculiarities of digitalization in the tourism and hospitality sector and its role in attracting tourists to the regions, enhancing the performance and competitiveness of tourism and hospitality enterprises. The article analyzes the introduction of digital technologies by small enterprises of the tourism and hospitality sector and reveals the problems arising in the digitalization (insufficient knowledge and experience Internet resources' use). It is proposed to use the experience of Germany, where regional authorities prepare business coaches for the development of tourism, to intensify the application of digital technologies by small enterprises. The business coaches provide consulting assistance to owners of small enterprises in the tourism and hospitality sector concerning the use of Internet resources for the promotion of their services both in the German national market and beyond it. This experience is useful in Russia for the development of regional tourism.

1 Introduction

In the last ten years, there has been a worldwide growth in the tourism sector. Compared to 2018, the number of trips increased by 4%. UNWTO experts suggest that in 2020 growth will persist and reach 3–4%. However, it should be noted that UNWTO experts projected higher growth rates of tourism across the world in 2019. The negative impact on the tourism sector has been exerted by the upcoming Brexit, the bankruptcy of Thomas Cook company, geopolitical tensions, and the global economic downturn. The UNWTO notes that since 1998 the number of states that replenish the state budget from tourism by more than 1 billion dollars per year has doubled. Based on this information, we can conclude that tourism is one of the sectors of the world economy with stable growth rates.

At the same time, tourism experts understand that progress is impossible without digitalization of the industry that will facilitate and make efficient the establishment of communication between tourism staff and customers. Most travelers intensively use various Internet services, websites, social networks for the planning of trips, leisure, communication, therefore, all tourism and hospitality enterprises from small companies and accommodation facilities to large international network operators should keep up with new trends, which indicates the relevance of the research topic having practical importance for Russian enterprises in the tourism and hospitality sector.

2 Research Methodology and Information Background

For pursuing the goal of the presented study, namely, to discover the role of digital innovation in the hospitality sector, we have employed the following methods and approaches such as information acquisition and analysis, system analysis, in-depth study of the peculiarities of digitalization in enterprises of tourism and hospitality sectors, methods and procedures of competitive analysis.

The informational background of the article is made up of data of international companies, Internet data, personal interviews and observations of authors obtained in the course of the study.

3 Discussion and Research Findings

The program for the development of the digital economy of Russia until 2024 fixes five basic areas [1], namely statutory regulation; HR and education; development of research competencies and technological groundwork; information infrastructure; information security.

The information infrastructure is of particular importance for the tourism sector because it provides communication between all entities of different management levels and the tourism and hospitality sector [2].

The information infrastructure of the macroeconomic level of management is provided by international organizations specializing in the coordination of states' activities in the field of tourism and hospitality development (UNWTO, WTTC, etc.), national tourism administrations (NTA) and national tourism organizations (NTO).

The information infrastructure of the meso-economic level is made up of tourist regions and their regional and local bodies, which are responsible for regulating the operation of tourist and hotel enterprises in their territory. The microeconomic level of tourism is represented by enterprises of the tourism and hospitality sector that are responsible for information provision of the industry [3]. The development forecasts of the world hotel industry until 2030 made by international hotel operators and Amadeus company also prove that the main trend in the performance of hotel enterprises will be [4] the aggressive use of mobile payments to book hotel and travel services, as well as their customization, based on a database of customers, their demands, preferences, habits.

Today, customer behavior is dramatically changing [5]. Customers addresses for hotel or travel services to well prepared and informed professionals and wants his information on the travel/hotel product to be supplemented and expanded because maybe he has already made a decision based on information from a virtual friend in a social network. A modern consumer is online around the clock and prefers to get information, book, pay for services online in time and place convenient for him. It is obvious that digital technology has a tremendous impact on all sectors of the modern economy, including tourism. This factor is particularly important for tourism in relation to streamlining of processes and services like baggage handling through networked/chipped suitcases, internal navigation at airports or digital access systems in lounge areas. For example, Lufthansa offers an electronic keychain for a suitcase, an electronic airport guide or new electronic access systems to airport lounges.

According to the expert of the Travelport company [6], five new technologies should completely transform tourism and hospitality enterprises: Internet of Things (IoT) or Internet of Travel Things (IoTT), mobile technologies, artificial intelligence, Big Data technology, cloud technologies.

With the help of virtual reality, tourists can visit the places where they would like to spend a vacation long before the trip. The Internet of things opens up unique opportunities for tourists. For example, using a mobile device, they can order room service in advance, set the desired temperature, receive various real-time notifications and much more. For the execution of these tasks, mobile devices need advanced artificial intelligence. Contemporary artificial intelligence systems with access to the latest databases provide the tourism and hospitality industry with virtually unlimited capabilities in customization of the tourist and hotel services.

Big Data makes it possible to predict consumer actions with high probability. Access to the required computing capacities is provided by cloud technologies that

have high data throughput and allow tourism enterprises to maintain high performance even under maximum workloads. Cloud infrastructure enables quick and efficient processing of a large bulk of data, which allows providing high-quality services to tourists. During the Fourth Industrial Revolution, the ability of the tourism and hospitality enterprises to provide modern customer service depends on the knowledge of how to apply these technologies. In other words, the enterprises should be ready to provide the consumer with a range of personalized services in a digital environment in the shortest terms. Obviously, this also concerns small and medium-sized enterprises, for which the solution of digitalization problems is a serious financial and organizational challenge [7].

To retain business positions, small tourism and hospitality enterprises should develop their own digitalization strategy, learn the staff how to use new technologies and choose a good business coach among the staff who will help to accomplish the tasks aimed at automation of the company's business processes [8]. The employee holding this position should pass appropriate retraining and oversight the automation of processes at the enterprise, helping other employees to learn new information technologies. The staff with new competencies will be able to better explore the individual needs of each guest, which allows providing travel/hotel services at a higher level, which will affect the best way on the revenues of the enterprise. Thus, the prerequisites for the successful transition of a small tourism and hospitality enterprise to digitalization are proper digitization of Customer Journey, staff training, and own business coach.

Unfortunately, nowadays over 35% of small enterprises do not have enough Know-how in the field of digitalization and about 36% of small enterprises do not have the funds for modernization [9]. Some of them can't decide on the terms of the business processes automation, 48% need professional advice and cannot estimate the economies of scale from technologies. According to experts, small enterprises should pay special attention to work with e-mail (responding to the questions of potential customers in a prompt manner), the website of the enterprise (it should be informative, concise, containing high-quality photos, convenient for direct booking, available feedback) and promote their business via social networks and online travel agencies (OTA) [10].

For large hotels and ones of international hotel chains, the problem of the industry's digitalization is not so severe, as they possess more resources and funds for modernization. Therefore, they scale up implementation of the technologies such as:

- artificial intelligence ("smart" hotel rooms where the guest can set the level of lighting and temperature or where several tens of languages are recognized);
- the employment of Application Programming Interface (API) to provide integration between the various technological systems used in hotels;
- the application of augmented reality technology for promotion of sales (for example, participation effect in a hotel room). Also, virtual and augmented reality, including ones with touch sensations, can be implemented by digital concierges

when giving recommendations to the customer on various issues and leisure activities;
- the use of voice assistants, which helps the hotel guest to get entire information about the hotel, order services from the hotel room, find out information about various facilities in the hotel and out of its territory;
- the exploitation of courier unmanned vehicles to deliver customer orders, suitcases, as well as receptionist robots that will follow the guest and execute his orders;
- utilization of the blockchain for acceptance of payments for the digital-money services to identify hotel guests;
- disposal of neural interfaces for management of various objects (for example, suitcases), as well as for the participation of hotel guests in interactive games controlled by the power of thought;
- the use of biometrics and face recognition technologies for identification and authentication of the client's identity.

Certainly, such technical innovations are not yet accessible to small enterprises of the tourism and hospitality sector, but their presence in the digital space is an urgent need for survival. However, it is quite difficult to get them without professional assistance.

The German federal state of Bavaria, which is commonly recognized as a popular holiday destination for both German tourists and foreign travelers found a very practical, but creative approach to the problem. The nature and attractions of this area attract tourists from all over the world, and only some of them want to live in large and expensive hotels. Many tourists would prefer to immerse themselves in the considerations of local life and culture and get acquainted with the traditional Bavarian way of life, customs, and cuisine. The solution to this problem is living in small family hotels, apartments in interesting small towns and villages. Unfortunately, the owners of such accommodation facilities do not always care about the representation of their small business in the digital space.

At present, almost no one books a hotel room by telephone, less and fewer tourists visit historical and architectural monuments, places of natural beauty and other attractions with guides and maps in their hands. Everything that can be digitized should be presented in a digital form. Even the smallest tourist enterprises in Germany, which are far from popular routes, do not want and cannot fail to keep up with new trends and dare for the crazy experiments, but, unfortunately, they do not always understand how to make it properly. In Bavaria, earlier than in other federal states of Germany, people came to the idea that business coaches who can train small business owners in the tourism and hospitality industry should help these people in the digitalization of their business.

Besides, on the initiative of the Ministry of Economy of Bavaria and under the support of its partners, a digitalization program of small tourism and hospitality enterprises, as well as on-site training of business coaches as part of it has been launched. It became obvious that people need Face-to-Face consultations and the so-called e-coaches, business trainers in the digitalization of small enterprises already

work in 17 regions of Upper Bavaria. They give a piece of advice to their clients in rural areas far away from big cities, which is especially important in mountain villages and lakes of Alpes. With their help, small enterprises of the tourism and hospitality industry will manage to survive in the competition for the client. As a study of the Bavarian Ministry of Economics showed, the need for such a program is long-standing, as many small enterprises do not have professional websites in different languages, online booking option, customer feedback to make a positive opinion about accommodation facilities among potential consumers, etc., and don't pay much attention to social networks and other Internet resources for promotion.

The huge impact of digitalization on the tourism and hospitality industry is acknowledged by the owners of small enterprises, but they do not always understand how to manage work in the new conditions [11]. Consultants advise starting with a continuous update of the enterprise's website since if a potential client sees outdated information on the website of a small accommodation facility, he will think that the hotel has both the outdated website, plumbing equipment and furniture in the rooms and will choose a large modern hotel. Photos posted on the hotel's website should be made by professionals and the website itself should have a responsive design so that the clients can easily use it from any gadgets (computer, laptop, tablet, smartphone). But most importantly, they should be convenient for booking (die Buchbarkeit) [12]. The consultants working under the program do not impose their recommendations, they only point to the owners of the accommodation facilities to their efficiency. It is clear that for many owners of small accommodation facilities it is quite difficult to design a multilingual website and constantly update its information, but they can ask their guests to leave feedback on the website and social networks, which will help to promote the facility on the Internet [13].

Upper Bavaria has always been popular among tourists, as visits to major world-famous cultural centers (Munich, Nuremberg, and the popular resort of Bad Füssing) can offer tourists who want to run from the noise of modern megacities and improve their health, many small family hotels in quiet provinces and the countryside. Agricultural tourism on a peasant farmstead is also possible. At the same time, authorities endeavor to avoid over-tourism, disturbing the daily life of the local population. The Tourism Department has been upgraded in recent years, and the Tourism Center has been established in 2019 based on the University of Applied Sciences in Kempten for exploration of new trends and give new impetus to the development to small enterprises of the tourism and hospitality industry. To this end, a variety of recommendations and guidelines for the digitalization of small enterprises in the tourism and hospitality industry, as well as various applications, are being developed and Internet channels are being managed. These activities in Bavaria are performed under the motto "Try everything and learn from each other at free will" [6]. The regional authorities intensify the engagement of market experts in the promotion of their lands to advertise not only famous Bavarian brands, such as Neuschwanstein, Lindenhof, Herrenkimsee, etc. but also regional, less popular destinations beyond Bavaria.

It's also possible to promote the region through digital marketing [14]. For example, the managers of the Beethoven Festival in Bonn gamble on Twitter. Since

2011, they have been inviting everyone to Tweetup. Twitter users have the opportunity to reserve seats in the VIP zone and, enjoying outdoor restaurant services, watch a concert on the big screen and immediately share their impressions on Twitter. Thus, a huge number of festival-related tweets under a preset hashtag appear immediately on the Internet. In 2015, the city of Bielefeld published urban pictures on Instagram, which one could post and get the right to visit for free one of the city's most beautiful sights, the tower of Sparrenburg Castle.

Thus, based on the analysis of the digitalization [15–17] experience by small enterprises of tourism and hospitality industry, we can argue that the promotion of any tourist destination involves not only the construction of large hotel facilities that meet the current needs of tourists but also consultancy to small accommodation facilities and assistance from regional authorities to increase their recognition on the Internet. The booking option of small accommodation facilities (and in most Russian regions of Russia they accommodate the main flow of travelers) will allow the regions to enlarge the flow of tourists and therefore replenish the regional budget.

4 Conclusions

Tourism is showing today a steady growth. At the same time, tourism specialists understand that progress is impossible without the digitalization of the tourism and hospitality industry, which enhances the performance of business processes, comfortable travel, recognition of tourist and hotel facilities, booking of services, communication between the staff of hotel and tourist enterprises with their customers. For large hotels and ones that are a part of international hotel chains, the digitalization of the industry is not an issue. A stable financial status and broad experience in the hotel business allow them to introduce new innovative technologies for the provision of services. However, a significant role in the tourism and hotel business around the world is played by small enterprises, for which it's much more difficult to adapt to the demands of the modern digital society without professional assistance. In Bavaria, earlier than in other federal states of Germany, people recognized this problem and the Bavarian Ministry of Economics has developed a training program for business coaches on the digitalization of small enterprises in the tourism and hospitality industry, who will advise and learn owners of small accommodation facilities on site. The training is aimed at the design of an interactive website with a booking option, as well as the promotion of hotel services provided by small enterprises and communication with customers via social networks and online travel agencies.

It makes sense to actively use the German experience in Russia for the development of domestic and inbound tourism using the resources of small accommodation facilities, which tourists do not even know about because they don't promote their services on the Internet.

Systemic Analysis of the Consequences of the Financial Market Digitization

Ksenia V. Ekimova, Nikolay V. Kuznetsov, and Olga I. Larina

JEL Classification G22 · O30

1 Introduction

Market does not produce objects, but passes information about them" (Friedrich August von Hayek). Any market is a means of interaction between manufacturers and consumers, based on a decentralized mechanism of pricing signals, which performs the most important functions in economy: distribution and redistribution of the main production factors; stimulation of development and technical progress; differentiation of revenues of market subjects. A Smith wrote about an "invisible hand" of market, which—through an impersonal mechanism of pricing signals—coordinates the scattered actions of manufacturers and consumers, each of which seeks their own interests. Thus, such mechanism and the most important part of any modern economy is financial market, which also has different participants, which seek individual interests of obtaining profit, but also features rational redistribution of financial resources in the economy.

The Bank of Russia defines financial market as a "system of economic and legal relations, connected to use of money as a means of accumulation and payment and turnover of financial tools, as well as the cultural and business environment in which

the participants of the financial market act. The public function of financial market is effective distribution of financial resources and risks and establishment of fair prices for financial assets" (The main directions of development of financial market of the Russian Federation for 2019–2021). Thus, financial market is a market that is a place of redistribution of temporarily free financial assets between various subjects of economy through execution of deals with financial assets. The list of financial assets is rather wide and has a tendency for further expansion and modification: financial assets; deposits in banks; checks and currency; insurance policies; credits; obligations of other companies and organizations for payment for delivered products (commercial credit); shares and other securities; gold, derivative financial tools, digital assets, etc [1–7].

Due to the above, the structure of financial market could be analyzed from different points of view: from the position of an asset of the position of subjects—articipants of financial market. Analysis of the structure of financial market by the type of assets shows that the segments of financial market are stock market, credit market (which includes money market), and capitals market. It is also expedient to include in these segments the following markets: currency market, bullion market, and insurance market. A relatively new segment of financial market is market of digital assets (including so called crypto currencies and/or virtual and/or network money), which appeared in 2009 and has been actively developing in recent years. Based on identification of the financial intermediary, it is possible to distinguish the following segments: market of bank services, market of micro-financing, market of insurance services, market of payment services, market of lease and factoring services, market of investment products, and market of pension savings. It is necessary to understand and take into account that limits of the above segments are rather conventional, and that the segments of financial market often cross each other. This paper analyzes financial market from the position of application of digital financial technologies in its main segments.

2 Methodology

2.1 Analysis of the Structure, Modern State, and Dynamics of Development of Financial Market in Russia

The basis for distinguishing the segments of financial market is that their common feature is redistribution of temporarily free financial assets—which allows uniting these segments under a common title "financial market". Each of these segments has its specific features, which makes them separate components of the market. Financial market is not just a means of redistribution of financial resources in the economic system, but also a very important indicator of the state of all finances and the economy on the whole.

Thus, the state of Russia's financial market as of early 2019 could be characterized by the following facts and numbers (early 2020 is not analyzed, because it is peculiar for mostly stress scenario of development). Russia's position in the ranking of countries by the factor "Development of financial market"—107th out of 137 (the leader is New Zealand) (https://www.weforum.org/reports/the-global-competitiveness-report-2017-2018-4). The ranking contains the following indicators: sustainability of banks—121st position, regulation of stock markets—112, easy credits—110, possibility of receiving financial services—101, pricing accessibility of financial services—94, financing through local stock market—90, possibility of obtaining venture capital—89, and legal rights index—49.

According to the mega-regulator, the Russian model of financial market is very much similar to the models of other countries with emerging markets—Indonesia, Argentina, Kazakhstan, etc. (The main directions of development of financial market of the Russian Federation for 2019–2021-3). The specific features of such model are as follows: domination of banks over non-credit financial organizations (insurance companies, pension and investment funds, etc.); foundation of economic agents on their own assets during investing; predominant role of the budget and intercompany channels in redistribution of financial resources as compared to the channel of financial mediation.

The Russian financial market is peculiar for low activity of population in the Russian financial market and mistrust to its non-bank financial intermediaries. The structure of population's financial assets is dominated by bank deposits, which is largely predetermined by the system of insurance of deposits and the measures for regulation and strengthening of the banking sector. The above thesis of the regulator contradicts an international study, which emphasizes that one of the vivid Russian problems is low sustainability of the banking system. However, as of March 1, 2020, there were 396 banks in Russia (436 credit organizations in total).

The Russian financial market also has other specific features: financial & economic sanctions against Russia limits the capabilities of Russian organizations in financing; there is a regional disproportion (presence mainly in the Central Federal District); high level of concentration in certain segments of the market. On the hole, there is a developed banking segment, in which five largest credit organizations—banks—account for more than 60% of total assets. Thus, poor development of market capital and absence of other institutional investors (insurance companies, non-government pension and investment funds) limit the economy's abilities in transformation of population's savings into long-term investments that are necessary for sustainable growth of economy.

It should be noted that capitals market is a part of financial market in which instruments with the turnover of more than one year are traded. Capital market features redistribution of free capitals and their investing in various profitable financial assets. Capital market is the most important source of long-term investment resources for governments, corporations, and banks. Capitals market is connected to money market—market of short-term operations below one year, which features redistribution of liquidity. Money market services mainly the movement of current assets of organizations and short-term liquidity of banks and the government. Recent

Table 1 Capitalization of the main crypto currencies by years

Crypto currency	Capitalization as of January 1 of the corresponding year, USD million			Coefficient of capitalization growth 2018/2016
	2018	2017	2016	
Bitcoin	229,119.155	16,050.488	6,529.234	35.1
Ethereum	74,724.137	714.824	72.130	1,036.0
Ripple	92,586.556	363.373	335.374	276.1
Bitcoin cash	41,081.678	–	–	–
Litecoin	12,499.051	221.640	153.956	81.2

Source Compiled by the authors based on CoinMarketCap (https://coinmarketcap.com/)

year have been peculiar for quick development of market derivatives of financial instruments—instruments of treading financial risk, which prices are connected to another real or financial asset (product, shares, currency, or interest rate).

Derivative financial instruments also include digital financial assets, which are not an independent form of money but a derivative instrument, which has value only in interconnection with real currencies. The specifics of such digital money are that it is not supported by real legal money, bullion, or any other type of products; also, they do not have legally responsible subjects. It should be noted that absence of cover of money leads to strong volatility of the currency rate, which is determined not by its real purchasing power but by the balance of demand and offer in the market—as cost of crypto currencies is based on economic expectations, not on presence of real assets. The most profitable and popular crypto currency in the world is Bitcoin—its capitalization is more than USD 112 billion.

Over three recent years, the market of crypto currencies has been showing high growth, with the highest coefficients of growth observed with crypto currencies Ethereum and Ripple (Table 1); the main growth was observed in 2017. These crypto currencies were introduced later than others, but have already exceeded their capitalization. Thus, the aspects that influenced capitalization of Ethereum were integration in the cloud platform Microsoft Azure, and growth of Ripple is stimulated by high speed of transactions and low commission on operations.

Analyzing the modern state of the market of institutional investors, the following should be noted. As of July 1, 2019, Russia's insurance market had 268 subjects of insurance services (Official web-site of the Central Bank of the Russian Federation [8]. The volume of insurance premia for insurance contracts showed annual growth of 15.7% (including the share of premia for voluntary types of insurance—83%, mandatory—17%). In the structure of insurance premia for voluntary types of insurance, life insurance accounts for 37%, and property insurance accounts for 29%. The least popular types of insurance are financial risks insurance (less than 1%) and entrepreneurial risks insurance (1%). In the structure of insurance premia for mandatory types of insurance, compulsory civil liability insurance of owners of motor vehicles accounts for 90%, and compulsory personal insurance accounts for (8%).

Thus, the main tendencies in development of Russia's financial market are as follows:

1. Reduction of the number of market participants, including the process of mergers & acquisitions, continues;
2. Small participants of the market are ousted because of competition;
3. Increase of the regulator's requirements; not all market participants can bring the normative indicators in accordance with new requirements of the regulator;
4. Substantial concentration of market;
5. Most of the financial operations are performed by banks;
6. Online sales and online services are developing (payments, services, and online policies);
7. New digital tools appear—but their segment is not large yet.

Further development of financial market will be determined by a lot of factors, including fundamental characteristics of country's socio-economic position and diversification of the whole economy; level of revenues and well-being of people; level of development of state and legal institutions and level of their real influence on domestic processes; integration of the Russian market in the global financial markets and tendencies of their development.

3 Literature Overview

3.1 Digitization of Financial Market

Development of financial market will be oriented in the short-term at application of new technologies in companies that want to occupy the leading positions in the market. It is considered that digital technologies are the most probable point of growth of insurance [9].

There has been developed and adopted the National program "Digital economy of the Russian Federation", which aims at elimination of Russia's technological underrun and at implementation of new modern technologies for the economy's effectiveness (Passport of the national program "Digital economy of the Russian Federation", 2018). In this Program, financial digital technologies, including blockchain, are considered to be among the most perspective technologies. A range of works dwells on the issues of application of blockchain technologies [10, 11].

Analyzing digital technologies, which could be applied in financial market, the following directions should be noted: analysis of Big Data and predictive analytics; chat bots; robotics; optical recognition of data; AI; Internet of Things; virtual and alternate reality; blockchain. This research allows concluding that for Russian financial organizations the most attractive directions are "Big Data analysis and predictive analytics" (84%), "Chat-bots" (60%), "Robotics" (56%), and "Optical recognition of data" (56%); also, there's interest in "AI" (40%) and "Blockchain" (32%). The

"Blockchain" is more interesting for organizations of the financial sphere than for organizations of other spheres.

It is considered that technologies of distributed register (blockchain) have large perspectives, especially in the financial sphere. Certain forecasts say that the average rate of capitalization of crypto currencies in 2017–2023 will constitute 33%, and banks will save USD 20 billion in 2022 due to use of blockchain. According to the same forecast, 10% of global GDP will be stored in blockchain systems in 2027. According to the forecast of development of the market of the technologies of distributed register, it will grow ten times in ten years.

At present, only 1% of organizations use blockchain,[1] but positive effects from use of this technology could influence the future picture and the essence of financial systems. Thus, this technology has the following effects for different spheres of the financial sector:

- increase of security of transactions and data storing;
- conducting direct payments without intermediaries, which will reduce their number in the financial sector;
- simplification of international transfers and modernization of the currency exchange market;
- transition to another model of pricing for financial services, which is based on factually performed operations;
- formation of smart contracts;
- development of cryptography.

It should be noted that blockchain is the basic technology for formation of peer-to-peer payment systems and the basis for development of crypto currency systems. Therefore, application of this technology is oriented primarily at the banking and payment segment of the market. However, other participants of financial market also could implement these technologies.

There are examples of foreign startup projects in insurance. Etherisc used Ethereum blockchain to develop a decentralized insurance platform and started a product for insurance payments for flight delays; startup Teambrella provides services of P2P insurance. In case of an insurance event, the decision on compensation is made after discussion and voting. The Russian practice has an example of *Renesans Strakhovanie,* which, together with *Delovie Linii* (cargo transportation), implemented a project of smart-contract based on the system of blockchain Hyperledger (IBM).

Thus, we see application of digital financial technologies. Such technologies could lie in the basis of different financial products: from direct crediting between individuals to use of Big Data and robotics. Market of such products is growing around the world. The most "revolutionary" technology, which could change the modern financial landscape, is the technology of distributed register, based on which new peer-to-peer payment systems, systems of direct crediting and investing, virtual currencies, and "smart" contacts are created.

4 Analysis of Results

4.1 Pros and Cons of Digital Technologies

Digital financial technologies allow raising quality of life and increasing accessibility and speed of receipt of financial products for population and business. The main advantages of financial products are increase of effectiveness (financial processes become simpler, quicker, and more convenient) and optimization of customer services (minimization of operating expenditures and increase of convenience for users). From the position of state regulation, digital financial technologies allow making financial operations more "transparent" and controllable.

Application of different digital technologies is predetermined by search for the optimal way of doing business; however, there are certain risks of application of such technologies. At present, there a lot of studies devoted to the digital economy and digital technologies in the financial sphere, as well as information risks and cyber risks and threats [10, 12–14].

However, the number of complex works that analyze opportunities and threats of application of digital technologies in the financial sphere is small. Having studied the sources and generalized the experts' opinions on this issue, we performed SWOT analysis of application of the technologies of distributed register.

SWOT analysis of application of the technologies of distributed register

External environment	*Opportunities* 1. Development of economy leads to demand for technologies 2. Growth of investments in fintech industry due to its commercial attractiveness 3. Government support for digitization 4. Large share of population that use information technologies 5. Increase of efficiency and reduction of expenditures by reducing the number of intermediaries and commissions 6. Quick exchange of information 7. Possibility of application in various spheres of science and technology	*Threats* 1. High level of competition and appearance of large foreign players in the market 2. Reduction of number of organizations 3. Consumer conservatism 4. Developed and traditional business processes with organizations 5. Multidirectionality of state policy 6. Absence of stability in the market 7. Low level of participants' awareness 8. Absence of systemic regulator 9. Criminal and fraud schemes with the usage of technologies

(continued)

(continued)

Internal environment	*Strengths* 1. Protection of data confidentiality 2. Possibility of provision of integrity and protection from unsanctioned access to information 3. Achievement of "decentralized consensus" and formation of "smart" contracts	*Weaknesses* 1. Cost of implementation of technologies and the need for large investments for development of technologies 2. Expansion of the number of participants reduces the speed of functioning 3. Errors of the program code and probability of technical failures

Source Compiled by the authors

The performed analysis shows that as of now—in the initial period of development of digital financial technologies (when their legal state regulation is being formed, and large conservatism of consumers remains)—external threats of application dominate.

5 Conclusions

5.1 Threats and Risks that Accompany the Implementation of Digital Technologies

As was noted above, a perspective technology for financial market is the technology of distributed register, based on which digital financial assets are created. Use of digital technologies entails certain threats and risks, which must be realized by the parties that use such assets or perform financial operations with them. The risks of their application are as follows (Table 2).

It should be noted that serious risks, which are peculiar for the turnover of digital assets, are aimed not only at a wide range of users—they could also undermine the systemic sustainability of the state. In our opinion, the most significant threat is the threat to stability of functioning of sovereign financial and public systems. This leads to the necessity for reconsideration of the regulating methods in view of new risks. In the short-term, development of digitization of the Russian financial market will be influenced by the following facts: adoption of digital law (it is highly probable that digital assets will not be available for inexpert investors); international experience and practice of application (thus, positive experience will stimulate other countries for development of similar financial tools); technological changes (development of technologies could lead to further technological modification of financial digital products).

Table 2 Risks of application of digital financial technologies

Risk	Manifestation of risk	Subjects exposed to risk
Loss of liquidity	Systems are autonomous and are not controlled by the regulator. It is impossible to forbid, cancel, or block a transaction	Consumers
	Irreversibility/irrevocability of a deals makes the recall of the performed payment impossible	Financial/bank systems
Risk in the sphere of fighting money laundering/financing of terrorism	Autonomy and absence of control from the government allow for fraud, money laundering, and financing of criminal deals, up to terrorism	Financial/bank systems; government
Legal risk	Limited application—it is difficult to predict a query and possibility of usage in payments	Consumers
	Applied only within one payment system	Financial/bank systems
	Illegitimacy—Russia has no legal field for usage of digital currencies	Government
Market	High volatility—the rate of formed based on demand and offer, which are formed under the influence of advertising, news, and private motives of market participants	Consumers; financial/bank systems
Operating	Technical dependence— the blockchain model has certain limitations, in particular, by the number of performed transactions and volume of stored data. The necessity for expenditures for technological update and improvement of the system Possibility of system failure Possibility of fraud—e.g., cyber squatting or use for criminal purposes	Consumers; financial/bank systems; government
Systemic risk	Digital currencies could be a speculative “bubble”, as they have no real value	Consumers; financial/bank systems; government

Digital Technologies in the Hotel Industry: New Prospects for Sustainable Development

Valentina A. Kolobkova, Aleksey A. Romanov, and Elena A. Frolova

Abstract The article presents an analysis of the prospects for the using of digital technologies in the hotel industry, identifies a number of problems and suggests ways to address them through the using of new digital technologies. Today, modern society can be described as informational. Everywhere there is a digitalization of enterprises, the conduct of the modern economy is being revised, and human labor is being robotized. The main results of digitalization are the same goods and services of the traditional economy, which are provided with the help of computer equipment and information systems. This has a number of advantages, the main of which is to increase the availability for ordinary users of certain markets (goods or services), and for enterprises to increase competitiveness and efficiency, expand the market for goods and services to increase sales volumes of the product. In the age of the global Internet, wide informatization of services, and digitization of economy, the tourism and hospitality industry changes quickly. The main task of this paper is to study the existing experience of application of modern technologies in the hotel sphere and to analyze the positive and negative aspects. Results: 1. Based on study of the practical experience of such organizations as Marriott, Samsung, and Legrand, a conclusion is made on the necessity for application of digital technologies in the hotel sphere for the purpose of improving the system of services' quality, reducing the service time, increasing the competitiveness of hotel companies, and reducing the costs of servicing the consumers. 2. The problems are identified in the selection process of hotel chain staff, which can be eliminated through the use of new digital technologies. Their application will help to reduce the time requires for search for applicants, perform the initial analysis of the applicants' data, skills, and experience, and improving the organization's electronic document turnover.

JEL Classification M10 · M15

1 Introduction

At present, digital technologies enter all spheres of the Russian economy. President Vladimir Putin noted, "We consider it necessary to accelerate the implementation of the whole "digital agenda" and coordinate efforts on development of the Internet economy, creation of common rules of digital trade and equal standards of information exchange and protection" [1].

This paper dwells on the issues of using digital innovations in the service sphere—in particular, hotel sphere. The novelty of the offered view consists in the fact that digital innovations open very wide perspectives for economic, confidential, and global communication, allowing solving the problems of production, management, advertising, market research, financial transfers, and security. Potential consumers could order products and services 24/7, regardless of their location.

We think that implementation of digitization in this spheres stimulates the increase of customer services, reduction of service time, reduction of services' costs, and provision of security of hotels' customers.

2 Methodology

The following classical methods were used during the research: analysis, synthesis, generalization, analogies, abstracting, and the method of the method of rising from the abstract to the concrete. Analysis of literature sources and Internet resources' data was used for defining the necessary notions: research recruiter, the Internet of Things, "smart home", and AI—robot [2–6].

The main task of this paper is to consider the application of "smart technologies", which are a unified system of modern hi-tech means of implementing innovations into the life of a modern society for correspondence to the rates of its growth and development. "Smart technologies" apply not only to the technical component (e.g., "smart home", which allows hotels observing the principles of lean production during provision of their services and saving on utility payments) but also to improvement of the management system, including management of company's personnel and the system of promotion of services in the market (internet marketing).

3 Results

3.1 Stages of Implementing Digital Innovations into the Hotel Sphere

Increase of the quality of customer services, reduction of service time, reduction of services' costs, and provision of security of hotel guests in the conditions of development of the digital economy and implementation of digital innovations into the hotel sphere are an important topic of research in scientific circles and in the sphere of professional relations [7].

Digitization has an important role for customer accounting. There are a lot of different services that allow taking into account the availability of rooms and the number of potential guests.

Digital technologies become more important for promotion and advertising of a hotel product. Tourists and hotel owners try to use various options of communications, so that guest could select a hotel that conforms to their demands and so that hotels could expand their clientele.

The studies show that in the potential consumers' time spent for various media resources Internet accounts for more than 50%. While before 2013, TV had been the leader in the aggregate volume of expenditures for advertising, now this role belongs to Internet. Online market has become very popular. It is a complex of means aimed at communications with hotel guests, which are realized with the help of digital communications.

Internet marketing performs the following important functions:

- two-way communication between hotel, which is an advertiser, and potential customers—tourist companies or individual tourists;
- analysis of customers' feedback about the level of services in hotels;
- integration of various technologies (social, mobile, web, etc.) with sales and customer service;
- possibility of quick reaction to all changes in the market of tourism and hotel services;
- possibility to update the contents of ads;
- optimization of hotel product's sales;
- formation of hotel's positive image;
- expansion of hotel's clientele;
- increase of hotel's customers' loyalty.

Marketing departments of hotels use various means for performing these tasks. The most popular one is mailout. Certain marketing specialists note the reduction of effectiveness of this method—however, statistics show that mailout for a certain target audience, which has been selected by the specific characteristics, could achieved 5% of response, providing up to 50% of aggregate sales revenues [8]. It should be taken into account that 2/3 of guests are eager to receive e-mails once a month. Also, the

form is very important, for more than 50% of all e-mails are viewed on smartphones [9].

A lot of hotel owners strive to improve mailout, for they want to use e-mail to organize personalized communication with the clientele, in order to increase their guests' loyalty. Thus, an international hotel Provenance Hotels and its project supervisor Rebecca Habbard started using a program Revinate Marketing™, which combines an automatized marketing platform and data base of customer data [10]. These tools, which are unified in Revinate Marketing, are used by Provenance Hotels to communication with the guests on a more personalized level [11].

There are also other types of Internet communications, which are successfully used for marketing in hotel business:

- video marketing in Youtube, Googlevideo, and Vimeo;
- hotels' web-sites;
- advertising which is oriented at specific demands of hotel services' consumers;
- communications in social networks;
- banner ads.

Together with the wide application of digital-technologies in hotel marketing, they are successfully used in hotels' hi-tech equipment.

Besides, the Internet of Things has become very popular. This notion was introduced by Kevin Ashton in 1999. The Auto-ID Center was created, which specializes in radio frequency identification (RFID) and sensor technologies; thus, this technology reached mass consumer [12]. "Smart home" has become rather popular in Russia. It is treated as an integrated network, which connects the surrounding objects of the real world and virtual objects.

In the hotel sphere, the Internet of Things increases comfort of rooms by automatizing the most important objects of utility-type equipment. Connecting hotel rooms to this system allows optimizing and automatizing the work of such elements as locks, A/C, fans, heaters, TV, illuminating devices, water mixers, safes, etc. Thus, a lot of hotels are equipped with intellectual energy systems of automatic shutdown of illuminating, heating, and ventilating devices when guests leave a room. This innovation has become very popular in the hotel sphere, as it allows hotel owners to reduce energy consumption. Equipping hotel rooms with smart locks allows raising the guest's security. In its turn, a thermostat measures the temperature in a room and regulates the work of heaters if the temperature drops down below the set parameters. Automatized thermostats will notify the engineering and technical workers of the hotel about the problems with the equipment and its possible malfunctions.

Large hotel networks actively develop "smart technologies". Thus, since 2017, an intellectual laboratory Marriott has been studying Marriott's own technical innovations and achievements of such giants of electronics as Samsung and Legrand. In the future, a hotel room will be equipped with everything necessary for a guest to control and set the most important parameters, including illumination and temperature.

As has been noted, hotel room is controlled with the help of mobile apps. Hotel's intellectual systems record consumers' preferences during previous visits (room

temperature, water temperature, illumination level, time of lifting of curtains, etc.) [13].

"We use mobile and voice technologies for allowing our guests to create a room that conforms to their needs", said Marriott's Global Chief Commercial Officer Stephanie Linnartz [14]. For example, Amazon's voice assistant Alexa can perform the orders "heating water in shower to the required temperature", "setting optimal illumination for reading", etc. Preliminary settings could be set on the web-site of the Marriott loyalty program. The innovations will be implemented in the course of give years [15].

In addition, the researches show that hoteliers are overloaded with a huge amount of technology at the present time. These are systems for data storage and processing and marketing technologies. They have to work with a variety of suppliers to attract guests and provide services. A typical hotel uses many systems for promoting its services—"sellers", who don't talk to each other, and in many cases, they don't even know each other. Someone sets up CRM, someone SEO, someone works for promotion in the media and so on.

Every functional structure from the finance department to the guest services department (cleaning, engineering, reception) works in isolation from each other.

Each department has its own technological tools, databases and suppliers, who don't interact with other departments.

The main obstacles to turning the hospitality industry into a digital and technologically savvy industry are as follows.

So, the reluctance to invest in digital technology, which is due to a lack of understanding that the need for the highest technology, is so necessary for travelers. In our digital age, hospitality technology goes far beyond a flat-screen TV and should focus on digital applications and devices for guests, such as voice assistants, messaging capabilities, mobile applications, personalization technology and personalized pricing and marketing applications.

The next one is an outdated accounting in the hotel business: most technological solutions for attracting, acquiring and retaining guests and many technological applications for servicing guests on-line are taken into account in the financial balance of the enterprise. In other words, these new technologies aren't depreciated as capital expenditures or are considered consumables. This fact makes many owners and managers reluctant to invest in new technologies that don't become the property of a hotel company.

Further, the using of technology differentiation is another serious problem and an obstacle to the progress that the industry is facing today. Guest data is often hosted on multiple systems, which don't interact with each other.

In the most cases, CRM data isn't used to attract and retain regular customers. Problems in the settings often destroy the database of regular customers, focusing solely on attracting new ones.

The authors think that the modern market of digital technologies offers a sufficient choice of technical innovations that could raise the quality of customer services and time of services and reducing hotels' expenditures.

3.2 New Digital Technologies in HR Management in the Hotel Sphere

Unfortunately, the level of usage of digital innovations in organization and management of human resources in the hotel sphere is low; this also includes insufficient application of digital tools in the procedures of HR document turnover, evaluation of activities, and dismissal of hotel's personnel.

The HR market has real problems that are connected to the search for applicants for vacant jobs. One of these problems is that HR services cannot guarantee quick closure of openings when it is necessary to find an employee "for tomorrow".

At present, the activities of HR specialists in a large hotel network with large personnel turnover and a lot of free vacancies are brought down to execution of a large volume of routine work, which is actually very simple actions—namely, checking CV's, selecting applicants, and calling the applicants and asking them the same questions. HR departments of hotel networks have been experiencing problems with speed recently: success of hiring often depends on the speed of reaction to appearance of a new CV on Internet.

HR specialist is an IT specialist with several laptops, which are used to process the applicants' cases around the world.

We have studied the possibilities of applying digitization in HR processes and analyzed the main trends in this sphere, as well as the issue of the modern organizations' need for the functioning of HR management services. The following conclusions have been made.

The practice of the Russian Federation shows that a lot of companies implement IT that allow performing personnel selection.

It turns out that a lot of functions of research recruiter could be performed by a hyper-efficient AI—Robot Vera. It was used to automatize certain business processes for HR specialists. Robot Vera could check a newly published CV, contact its author, and convince the applicant in company's interest. Robot Vera allows a company to close 10–100 openings very quickly.

Thus, MTS PJSC selects personnel based on the technologies of Robot Vera. The Robot searches for applicants' CV's by the set parameters on various recruiting platforms. Then it calls them, tells them about the vacancies, conducts the initial interview, and passes the information about the applicant to the HR department, which will make the final decision. Robot Vera brings the emotional burden on HR specialists down to the minimum, reducing the number of calls with refusals.

Any company that has purchase this product could create their own script for an interview call. For this, it is necessary to put in the data on the vacancy, the city of the vacancy, and requirements and responsibilities. It should be noted that this HR bot was developed by Russian specialists, and it becomes more and more popular in foreign markets.

Despite a range of advantages of using digital recruiters, there is a drawback, which consists in the problem of digital recruiters' recognizing applicants' speech.

The next stage of working with human resources has been studied based on the results of practical activities of Proaction—a developer of the system of attestation and business evaluation of personnel. It has been determined that this platform allows evaluating not only job suitability and level of adaptation but also personnel's satisfaction, loyalty, and involvement in the company's activities. The analyzed system of attestation and business evaluation of personnel offers a wide choice of methodologies that could be used by employer for testing and evaluating personnel. The most popular methods of digital evaluation include evaluation 360, individual evaluation for formation of HR reserve, and collection of feedback at the stage of adaptation. Proaction has been already implemented by Gazpromneft, Diksi, Bushe, Ulibka Radugi, etc.

There are also programs for remote commands. These apps could be divided into blocks: messengers (Zoom, Slack, Telegram, Hangouts), visualization tools (Trello, Sketch, Draft), systems of document and data storage (GoogleDocs, OneNote), and programs for control of the results.

Some companies use digital technologies not as a replacement but as a tool for more convenient and quicker work with personnel that exceed 500 people. For example, a cloud system Workday allows for significant optimization of HR document turnover. This system would be especially valuable for branches of international companies that are located on the territory of the Russian Federation.

For solving the problems of optimization of HR document turnover, it is planned to reform the main HR document—work record book. Starting 2020, electronic work record book will be introduced in the Russian Federation. A new digital form is to ensure constant and convenient access of people to the information about their labor activities and access of employers to new possibilities of HR accounting [7]. Transition to electronic work record books will be voluntary, and the paper form could be preserved as well. However, people who will start their labor activities in 2021 will have only an electronic work record book. All data on their labor activities will be recorded in the electronic form by HR specialists.

It should be noted that transition to electronic work record books is regulated by the laws of the Russian Federation. In view of implementation of this system, employers will have to organize work on correction of the local normative acts that regulate the organization's activities and revision of agreements and collective work contracts.

In view of the above, it seems that the whole cycle of personnel activities—from selection, evaluation of activities, and dismissal of personnel—could be conducted with the help of digital technologies.

We think that use of digital technologies will not lead to reduction of significance of HR specialists in the classical sense of this profession, and digital recruiters will become an effective tool for solving the problems of managing hotel networks' human resources.

4 Conclusions/Recommendations

The article mainly deals with applied issues related to the problems of using digital innovations in the hotel industry.

Summing up all of the above, the authors note the selectivity of companies in choosing digital tools in their activities. There are several reasons for this behavior, the main of which is the cost of implementing ERP systems and other digital systems/cognitive technologies. Also, the lack of readiness of top managers to drastic and comprehensive measures in the hotel sector affects.

We believe that the main goal of introducing new technologies into the hospitality industry is creating a single base, a comprehensive solution, which allows hotels to acquire new guests and keep regular ones by combining digital marketing, website and CRM data into a single integrated marketing and personalization platform.

Assessing the Efficiency of the Digitization Process of the Russian Transportation Industry

Inna S. Prokhorova

Abstract The authors of the paper have set up a problem of building a fundamentally new networked integrated transport infrastructure, described digital transformation as a system of reengineering of business process that globally restructures the business model, changing the quality of productive forces, forming new business processes. The essence of the process of digitization of the transportation industry has been defined as building a fundamentally new networked integrated transport infrastructure providing interaction between citizens, government agencies and institutions, business and transport in a single information field. Research methodology was based on the concept of digital economy as an economy based on global cross-border information flows and data exchange connected in a network managed by integrated intelligent systems based on the principles of the end-to-end digitization of all economic assets, processes and entities. The scientific novelty of the research is that the efficiency of the digitization process of the English transportation industry was for the first time ever assessed through the analysis of the compliance of digital platforms and services, implemented within the scope of the program of digital transformation of the transport system and the adopted funding strategy for the information and transport infrastructure. The analysis was carried out by systemization and generalization of regulatory, statistical and other information from the logistical point of view in terms of establishing rational relationship between material, financial and information flows in the new digital integrated data system. Based on the research findings, conclusions were made on the poor efficiency of processes of digitization of the transportation industry of Russia. Such drawbacks were identified as a small part of breakthrough technologies for the implementation of the transport digitization program, insufficient preparedness of the urban transport system for the introduction of platform "Smart City", and lack of balance in the financing structure of digital technologies towards expansion of coverage of the transport system with wireless communication networks.

JEL Classification C 42 · L 90 · R 40

1 Introduction

The contemporary world has come into the fourth technological revolution, the primary characteristics of which include complete digitization of processes and entities, innovative materials, innovative production, and innovative management systems.

Today, the term "digital transformation" means the global informatization of society. This is a process of creation of a single digital transport area in the economy, based on the use of integrated intelligent systems, which unites all economic entities. Digital transformation is the apex of the introduction of information and telecommunication technologies, it focuses on qualitative transformation, business process reengineering in a new economy. Unlike automation and informatization, global digitization does not simply increase the productivity and efficiency of existing business processes, but creates new processes and new opportunities.

Digital transformation allows implementing innovative services of network management of resources and business processes, bringing together information components from various sources. Such integration makes it possible to simplify and optimize the costs of risk management mechanisms, as well as the services of analysis of the intelligent environment for management of knowledge and corporate legal framework. These processes are becoming much simpler today thanks to the Big Data. Progress, as well as external demand, are forcing manufacturers to change the pattern of interaction, and producers of infrastructural information components increasingly switch to service-focused schemes for implementation of services, making it possible to piece together various innovative projects.

The transportation industry of the country is a strategic national infrastructure facility. The global transformation of transport on the principles of digitization is currently one of the top priorities of public administration [1].

Today, there is a state-level challenge of building a fundamentally new networked integrated transport infrastructure providing interaction between citizens, government agencies and institutions, business and transport in a single information field through the creation of a digital platform of the transportation industry of the Russian Federation. To handle this challenge, the platform is expected to meet the following criteria [2]:

1. quality of services: simplicity and convenience in use, personalization to the needs of each participant in the transport process, simplified subconscious comprehension of the service;
2. speed of services: reduction of time to work with the service, information processing, and taking a decision on the transport process;

3. cost efficiency of services: reducing transport logistics costs for all entities in the transport process.

This determined the choice of the transport system of Russia as the target of research into issues of digitization of the Russian economy. The subject of research in this paper are digital platforms and services which are implemented within the scope of the digital transformation program in the transportation industry [3].

This research is aimed at assessing the efficiency of the digitization process of the Russian transportation industry through the analysis of the key projects of digitization of transport that are implemented within the scope of this program, as well as identifying their benefits and drawbacks.

In order to achieve results, regulatory documents [4–6] and statistical open source data on the implemented projects of digitization of the transportation industry [1, 7, 8] were analyzed.

2 Methodology

The research used general scientific methods, including idealization and formalization, as well as observation, comparison and abstraction methods.

The data for the research were obtained from the federal program "Digital Economy of the Russian Federation", the industry-specific program "Digital Platform of the Transportation Industry" (DPTI), and the program "Digital Economy" within the focus area "Information Infrastructure" of the transportation industry [4–6].

Research methodology is composed of scientific findings in the field of new digital economy [9, 10] and the digitization of the transportation industry [7, 11]. Fundamental provision consists in the concept of digital economy as an economy based on global cross-border information flows and data exchange connected in a network managed by integrated intelligent systems based on the principles of the end-to-end digitization of all economic assets, processes and entities.

The study of existing approaches to assessing the efficiency of processes of digitization of the Russian transport system has shown that today the studies are focused on the analysis and development of methodology of digital transformation of the transport system: principles, methods, breakthrough technologies, organizational mechanisms of digitization of the transportation industry [12–17]. At the same time, the assessment of the efficiency of digitization processes based on the comprehensive analysis of the practical implementation of the digital platform of the transportation industry makes it possible to build a knowledge base for the diagnosis of product and financial potential of the digitization strategy, which actually determines the novel nature and scholarly importance of the research.

Research methods were based on the study, systemization and generalization of regulatory, statistical and other information on the implementation of the program of digitization of the transportation industry of the country from the logistical point

of view in terms of establishing rational relationship between material, financial and information flows in the new integrated digital data system.

Innovative projects in the field of digitization of transport processes of Gazprom Neft, Aeroflot, OJSC Russian Railways, urban transport system of Moscow, and other transport companies and organizations were analyzed in the course of research.

The program of the digitization of the transportation industry, approved by the Ministry of Transport of the English Federation and implemented as "Digital Platform of the Transportation Industry" (DPTI) is based on the following principles according to the National Program of Formation of the Digital Economy [2, 4, 5]:

1. securing efficient interaction of providers of transport services and their users through the integration of the transportation industry into the international transport system based on the adaptive digital platform;
2. creation of digital platforms to implement the electronic document flow in accordance with international standards;
3. forming the well-developed infrastructure and digital environment for improving the system of management of the transportation industry and achieving the optimum utilization of the transport network.

The implementation of this project will enable automated filling the information resources of the Ministry of Transport with relevant unified data about all processes related to the transport sector.

The essence of DPTI consists in the integrated ecosystem of the transport area based on technologies of the digital economy:

1. Big Data processing and analysis;
2. simulation of transport processes based on information from various sources and different systems;
3. creation of applications based on technologies of distributed databases;
4. creation of smart transportation facilities through the aggregation of information resources based on DPTI;
5. introduction of information services for clients of services, for government authorities and business in the form of registers of information standards regulating the operation of various modes of transport, register of facilities and entities ensuring transport security, register of transport infrastructure and means of transport, etc.
6. creation of new digital services for entities of transport infrastructure, cargo transportation, and passenger transportation;
7. building new business processes of management of the transportation industry based on the electronic document flow, digital signature, neutrality in relationship with business and government institutions, single support information system, integration with international information systems.

It is expedient to consider the scale of digitization by modes of transport in order to carry out the analysis of preparedness of the transportation industry of Russia for the massive use of digital technologies and creation of a single digital transport platform.

3 Findings

Research findings are based on characteristics of innovative projects for the creation of a single digital transport area of the Russian Federation (Table 1).

Priority areas of funding for digitization projects in the transportation industry included two projects: covering transportation facilities with wireless communication networks (425 million rubles) and deployment of networks for the collection of telemetric information at the top-priority transportation facilities (400 million rubles) (Table 2). At the same time, investments in projects related to the "Internet of Things" and development of technologies for the digital transport platform are negligibly small: 30 million rubles and 10 million rubles respectively. The total amount of financing of the "Information Infrastructure" in the field of transport infrastructure during 2017–2020 was 865 million rubles.

According to the breakdown of costs for the implementation of the "Information Infrastructure" in the transportation industry, the bulk of costs will be compensated using the budgetary funds; major infrastructural corporations (GLONASS, RT-Invest Transportnye Sistemy and Russian Railways) invest in the development of networks for the collection of telemetric information (a total of 200 million rubles during 2019 and 2020).

4 Conclusions

Based on the research findings, one can formulate several conclusions on the efficiency of processes of preparedness of the transportation industry of Russia for the introduction of the digital platform:

1. introduction of breakthrough digital technologies for the implementation of the digital transformation program is still exclusive in nature; in most cases, this is either pilot projects or technical solutions at the design and development stage;
2. the top companies of the transportation industry, Aeroflot and Russian Railways, have information technologies that automate the complex tasks of management of the transport system making it possible to implement system digitization projects for the relevant mode of transport;
3. the rail transport is to the fullest extent prepared for the creation of a single digital transport area through the implementation of the project "Digital Railway" until 2030, since OJSC Russian Railways automated virtually all components of the transport system of the company;
4. the urban transport system of Moscow currently has partially digital technologies for the implementation of the program "Smart City—2030";
5. digitization programs are mainly funded using the funds of state budget with a view to developing communication networks suitable for wireless data transfer, i.e. related to the expansion of access to the wireless Internet.

Table 1 Innovative projects in the field of digital transformation of the transport system of the Russian Federation

Innovative project	Project scope	Project benefits
Transportation by road		
Gazprom Neft: "Digital Fuel Tanker"	Digital solutions for remote monitoring and control of fuel delivery using the highway transport	ComNews Award "Technology of the Year" according to Safety & Security Leaders
BigData, MosTrans	Simulation of situations and real-time car traffic forecasting	Efficient infrastructure management, detection of road congestions and selection of the shortest route with due account for the road situation for the driver
Transport information systems		
Unified State Information System for Maintenance of Transportation Security (USIS MTS)	Control of passenger transportation with a degree of detail up to a specific person, to a specific vehicle and passenger	Is fully competitive in Europe
State automated information data system ERA-GLONASS	Big data collection and storage	Services, that are not directly related to fee charged from heavy duty trucks that are necessary for the transportation industry
"Platon"	Amount of data processed and stored in the system: over 12 petabytes (12.5 billion gigabytes)	Second largest database in Russia
Transportation by air		
Aeroflot: SAP ERP	Integrated system for management of an enterprise, digital billing	Full electronic document flow 5th place in Europe in terms of volume of passenger transportation
Lufthansa Systems	Digital billing	Electronic system for accounting, billing and invoicing of air services provided
Sabre	Online booking system	Allows booking passenger seats remotely
crew tablet	Mini iPads for the provision of services to passengers by flight stewards	Patent-protected solution from Aeroflot
AMOS	Continued airworthiness and aircraft maintenance and repair system	Airborne time—not less than 12 h

(continued)

Table 1 (continued)

Innovative project	Project scope	Project benefits
Automatic dependent surveillance broadcast ADSB	Unmanned aircraft handling	Precisely determines the position of the aircraft in real time and transmits flight data (altitude, speed, positioning data of the aircraft) to earth-based control centers and other aircraft
FSUE ZashchitaInfoTrans, FSUE Superservis 22	Electronic freight management system	Implementation deadline—2024. The system includes: personal account of the carrier, electronic document flow, electronic reservation of time for crossing the state border of the Russian Federation
Rail transport		
Digital railway	Creating a single digital transport area	Has been implemented since 19.03.2019 in compliance with Decree of the Government of the Russian Federation No. 466-r
Satellite technologies	System of communication and monitoring of suburban passenger service; system of monitoring of transport of special and dangerous goods, control of shunting locomotives, train separation system, system of monitoring of maintenance vehicles, integrated security systems, etc.	Implementation deadline—2025 More than 16.5 thousand installed navigation systems More than 25 copyrighted patents
Automated integrated system for the diagnostics of high-speed transportation infrastructure facilities	Automatic real-time data processing	Noncontact measuring system for the parameter checkout at speeds over 200 km/h; simultaneous checkout of 76 parameters, video monitoring of the status of infrastructure facilities
Digital depot	Processing and storing data on depots with multidimensional analysis and prediction of models	Automated personnel management (mobile AWS) Automated management of assets (railway equipment) Automated service control

(continued)

Table 1 (continued)

Innovative project	Project scope	Project benefits
Smart railway station	Automated system of management of operation of the infrastructure and technical facilities of the railway station in a single information space	Partially implemented: Automated system of life-support management at the railway station—10 railway stations equipped Integrated Utility System (IUS)—8 railway stations equipped
Train control dispatching system	Single unified train movement dispatching system	More than 62 thousand kilometers of tracks are equipped with automatic block signal systems More than 128 thousand points are equipped with electric interlocking More than 69 thousand kilometers of fiber lines
Automated datapool of the freight car fleet (ADFCF)	The data base for the traffic management within the scope of automated systems of Russian Railways	Ensures monitoring of technical state and utilization of the freight car fleet
Electronic consignment note (ECN)	Automation of the complete technological cycle of execution of transportation documents	Forming a single centralized base of shipping documents
Intelligent Rail Transport Control System (IRTCS)	Automated system of management of complete operating process cycle of field operation	Forming a single model of joint testing ground which provides comprehensive description of former, current and forecast situation at the testing ground
Urban transport system of a metropolitan city (using the example of Moscow)		
"Smart City—2030"	Strategic project of transition from the conventional transport system of the city to smart mobility systems	Virtual presence of the resident in the traffic flow corresponds to reality, affordable car rental service, time saving, convenience in moving
Intelligent transport system of Moscow: traffic lights system, monitoring systems and video traffic surveillance system	Real-time analysis of data from surveillance cameras	More than 2 thousand traffic lights, 3.5 thousand traffic monitoring detectors, 2 thousand surveillance cameras
Single transport card "Troika" for individuals and legal entities	Payment for urban transportation and municipal services	Covers all modes of transport, validation is possible at the stations of transfer to other modes of transport

(continued)

Table 1 (continued)

Innovative project	Project scope	Project benefits
Single transport portal transport.mos.ru	Online reflection of traffic situation in Moscow, navigation services and remote replenishment of transport card "Troika"	Availability of an online service to search for a vehicle, check for fines, order passenger transportation services

In general, inference should be drawn that digitization processes in the transport sector are fairly efficient.

The novel nature of findings is characterized by the fact that they establish the knowledge base (indicator base) for assessing the product potential (the level and quality of development of IT-products) and financial capacity (accessibility of sources of financing) of implementation of the "Program of digitization of the transportation industry of the Russian Federation" [4].

Table 2 Volumes and sources of financing of the information and transport infrastructure

Works	Source	2017	2018	2019	2020	Total
Covering transportation facilities (including federal highways and railway infrastructure) with communication networks suitable for wireless transmission of voice and data	Budgetary funds	0.00	40.00	350.00	35.00	425.00
	Extrabudgetary funds	0.00	0.00	0.00	0.00	0.00
Developing the Draft Concept of development of narrowband networks using the LPWAN technology for the collection of telemetric information of transport infrastructure, taking into account solutions developed in the Concept of construction and development of wireless narrowband networks of the "Internet of Things" in the Russian Federation	Budgetary funds	0.00	30.00	0.00	0.00	30.00
	Extrabudgetary funds	0.00	0.00	0.00	0.00	0.00

Digitization in the Activities of Social Workers

Pavel V. Tereliansky, Nina A. Chernikova, Anna S. Shubina, and Elisaveta V. Terelianskaya

Abstract The paper analyzes the factors that are crucial for the digitization of activities of social workers of care-giving institutions that ensure provision of services for senior citizens and disabled persons at home or in inpatient facilities; a research that was carried out in the Volgograd Region is presented. The authors describe the issue of preparedness of social workers for using computers and the Internet in their practical activities in compliance with the requirements of occupational standard "Social Worker"; they have identified the main ways of transforming the system for the implementation of social protection measures and social care within the scope of social services and public social assistance in the context of digitization. A three-stage research was initiated and carried out by the authors in order to establish a path for tracking the digitization of activities of social workers: (1) identifying difficulties faced by social workers in the future digitization of their activities; (2) designing the content of training for social workers based on research results, organization and delivery of training; (3) identifying the results of training of social workers and evaluating further prospects for the digitization of their activities. Research findings: (a) the fundamental reasons behind the unwillingness of social workers to implement labor activities involving the use of information and communication technologies, have been identified; (b) ways of solving the problem have been considered through establishing training for social workers, their supervisory support at the premises of care-giving institutions. This support is aimed at identifying and compensating for the lack of competencies related to mastering information and communication

1 Introduction

The modern system of social protection of population is represented by institutions that provide social services to citizens who undergo transformations in the context of the digitization of society. Implementation of the "Plan of activities for improving the efficiency of implementation of social protection measures (support), social services within the scope of provision of social and welfare services, other social safeguards and benefits, as well as optimization of activities of the Ministry of Labor and Social Protection of the Russian Federation, Federal Labor and Employment Agency, Pension Fund of the Russian Federation, Social Insurance Fund of the Russian Federation, medical and social assessment institutions" (approved by the Decree of the Government of the Russian Federation No. 10974p-P12 of December 28, 2018) [1], necessitates improving the efficiency of implementation of social protection measures with the use of the Internet, web technologies and other information technologies and information systems.

We turn our attention to transformations, which have occurred in recent years at the level of the basic form of management of the social work with disadvantaged groups of citizens—provision of a wide range of social services to elderly people and disabled persons by social workers at home or in inpatient facilities (for example, psychoneurological boarding school) [2]. For your information, "Russian social workers have secondary education and deliver social services" [3, 4]. Based on the work by Korotkova [5] and our research, we shall present the collective portrait of a typical social worker (period of 2013–2015): woman; the mean age is 43 or above; education—no special education; personal qualities—sociability, humanity; computer skills—lack of skills or basic skills.

The adoption of the Federal Law No. 442-FZ of December 28, 2013 "About bases of social servicing of citizens in the English Federation" (went into effect on January 1, 2015) and the issue of Occupational Standard "Social Worker" (approved by Order No. 677n of the Ministry of Labor and Social Protection of the English Federation of November 18, 2013) [6] were the key moments in changing the activities of social workers who provide services to citizens at home. This standard defines such employment functions as "Provision of socioeconomic/legal services to clients of a social service organization", which includes such skills: "use Internet resources to provide citizens with state and municipal services, including filling in application forms"; as well as labor activities: "Assistance in preparing applications and other documents

necessary for obtaining state and municipal services, as well as in submitting documents, including via electronic means of communication and Internet resources", "Assistance in preparing and filing complaints, including by electronic means of communication…". These factors have identified two challenges in the activity of social services:

1. The need to teach information and communication technologies to social workers;
2. Introduction of wide-scale usage of computer and Internet resources in the activities of a social worker.

2 Background and Methodology

The actualization of trends leading to changes in the practice of social work in the context of digitization is presented by publications by Giffords [7], Kononova and Kononova [8], etc. The issues of professional development of social workers in a virtual environment are discussed in Serezhko [9]. The basis of training based on portrait features of such employee is a work by Gudova [10], where the concept of post-literacy is considered. Publications [11, 12] etc., reflecting approaches to teaching "computer literacy" to middle-aged individuals, may serve as the methodological basis for the management of the preparation process. It should be noted that the system transformation of education and education technologies in general influences changes in training methods [13].

A three-stage research was initiated and carried out in order to establish a path for tracking the digitization of activities of social workers.

Stage 1. Identifying difficulties faced by social workers in the future digitization of their activities (2015–2016).
Stage 2. Designing the content of training for social workers based on research results, organization and delivery of training (2017–2018).
Stage 3. Identifying the results of training of social workers and evaluating further prospects for the digitization of their activities (2019).

For the pursuance of the research, two questionnaire forms were developed in accordance with approved methods [14]. During stage 1 of the research, respondents were invited to answer the following questions:

1. Do you have a personal email account?
2. Do you have social media accounts?
3. Do you have at least one of the following electronic devices which you can use to access the Internet (personal computer, laptop, tablet, smartphone)?
4. What electronic resources do you use in your professional activities? What websites are the sources of information that you use most often?
5. What issues do you have when using electronic resources in your professional activities?

6. What benefits of using electronic resources in your professional activities you could point out?

During stage 2 of research (after training) social workers were invited to answer the following questions:

1. What electronic resources do you use in your professional activities? What websites are the sources of information that you use most often?
2. What issues do you have when using electronic resources in your professional activities?
3. What benefits of using electronic resources in your professional activities you could point out?

265 people were involved in the survey—practicing social workers of Volgograd and certain districts of the Volgograd Region, whose length of employment varies from three to twelve years. The age of social workers surveyed varies from 43 to 65. 55.8% of respondents have general secondary education, 21.9% of respondents have secondary vocational education, 17.8% of respondents have elementary vocational education, and 4.5% of respondents have higher professional education.

The responses to pending questions in the questionnaire were processed using the content analysis method, resulting in the identification of generalized units of the content analysis.

3 Discussion and Results

The analysis of findings from the first stage of the research facilitated the definition of problems in the field of digitization of activities of social workers. In particular, the first questions in the questionnaire have made it possible to assess the degree of involvement of social workers in the electronic environment as users. The findings are presented in Table 1.

Table 1 Distribution of respondent responses to questions about involvement in the electronic environment

Question	Frequency of responses to questions	
	Yes (in %)	No (in %)
Do you have a personal email account?	27.9	72.1
Do you have social media accounts?	35.5	64.5
Do you have at least one of the following electronic devices which you can use to access the Internet (personal computer, laptop, tablet, smartphone)?	40.8	59.2

Source Compiled by the authors

Table 2 Distribution of respondent responses to questions about the use of electronic resources (before training)

Electronic resource	Response rate (%)
I don't use them	70.2
Public Services	17
Electronic Registry	7.5
Data processing centers of the housing and utility sector and fuel and energy sector, Gazprom Mezhregiongaz, Volgogradenergosbyt	3.8
Website of the Pension Fund of the Russian Federation	1.5

Source Compiled by the authors

The findings demonstrate that only about one third of respondents have a personal email account and (or) a social media account; that said, 59.2% of respondents do not have any electronic devices which could be used to access the Internet. Therefore, the majority of practicing social workers are not active users, thus they may face real challenges due to their lack of user skills or poor user skills in the process of digitization of their professional activities.

The following questions in the questionnaire directly refer to the experience of using electronic resources by respondents in their professional activities (Table 2).

The findings demonstrate that the absolute majority of respondents (70.2%) did not use any electronic resources at all in their activities. Possible reasons behind that could lie in the fact that social workers do not own any personal electronic devices and have no necessary user skills; besides, they have poor awareness of what electronic resources can be used in the provision of various services to clients.

Most (17%) of those respondents who use electronic resources in their professional activities have pointed at the website of Public Services. Information about this resource has been widely distributed by various mass media, and some social workers personally accessed this site.

Much fewer respondents mentioned that they accessed the website of the Electronic Registry of the Volgograd Region, which allows to making an online appointment at the doctor's for the clients (7.5%), websites which allow transmitting indications of metering devices online (3.8%), and the website of the Pension Fund of the Russian Federation (1.5%).

As can be seen from the above, social workers do not fully use electronic resources that contribute to the optimization of their professional activities in compliance with the requirements of the Occupational Standard.

The data presented in Table 3 show that social workers associated the main difficulty of using electronic resources in their professional activities with poor skills of working with electronic devices (76.6% of respondents). In this regard, employees are afraid of making a mistake in the process of access to electronic resources, they feel awkward in situations where they have to ask for help from their younger

Table 3 Distribution of respondent responses to questions about the difficulties of using electronic resources in professional activities (before training)

Category of difficulties	Response rate (%)
Poor computer skills	76.6
The lack of a personal tablet or any other mobile Internet-enabled device	55.1
Social worker's lack of knowledge about what resources to use and how they can be used	52.8
Psychological unwillingness of clients to use electronic resources while interacting with a social worker	19.6
Concerns about the additional workload due to the digitization of activities	10.6

Source Compiled by the authors

colleagues, etc. In the following, overcoming this difficulty was associated with organized training of basic skills of working with computers, tablets and other electronic devices for social workers.

55.1% of social workers surveyed pointed out the difficulties of digitization of professional activities due to the lack of a personal portable electronic device that could be used during the visits to persons under their care.

The difficulty associated with the lack of awareness of electronic resources relevant for professional activity was pointed out by 52.8% of respondents. In this regard, it was necessary to organize provision of information to social workers on the capabilities of the electronic environment in their work with clients, to prepare reminder cards for them with a list of possible electronic resources and algorithms for their use.

19.6% of social workers pointed out that their clients (mainly elderly people) are cautious and distrustful when a social worker is trying to advert to the capabilities of the electronic environment. For example, elderly people feel calmer when the social worker will bring indications of metering devices, recorded on a sheet of paper, to a specified place at a specified date, instead of transmitting this information via the Internet. If this occurs, social workers should be patient and gradually prepare persons under their care to the transition to remote modes of interaction with certain institutions.

10.6% of social workers surveyed expressed their concerns about the additional workload due to the digitization of activities. Such concerns are developing in respondents as a result of their poor skills of working with electronic devices: these procedures take too much time for them and require much effort. The resources for training social workers and showing them the capabilities of certain electronic resources can be used to conceptualize digital environment for them as something that facilitates their professional activities.

Findings presented in Table 4 demonstrate that the majority of social workers (58.8%) did not realize any benefits of using electronic resources in their professional activities. Among other responses, social workers claimed that the primary benefit

Table 4 Distribution of respondent responses to questions about the benefits of using electronic resources in professional activities (before training)

Category of opportunities	Response rate (%)
Lack of benefits	58.8
Saving the time of a social worker	24.2
Preservation of own resources of a social worker (physical, emotional, etc.)	9.1
Improving the efficiency of service provision	7.9

Source Compiled by the authors

from the use of electronic resources is time saving—solving job-related problems online allows avoiding unnecessary visits to institutions (24.2% of respondents).

Social workers distinguished preservation of own resources (9.1% of respondents) as another benefit. Visits to institutions (for example, to the out-patient clinic for making an appointment at the doctors for a client) require physical and emotional effort, after which there is often a feeling of dissatisfaction. Therefore, digitization of activities of social workers can serve as a means of preventing burnout due to the improved efficiency of activities while minimizing costs.

Part of respondents pointed out the improved efficiency of service provision as a benefit of using electronic resources (7.9% of respondents): services are rendered in a more mobile way, time saving allows providing more high-quality social welfare services and other services.

Thus, the findings from the first stage of the research have shown that most social workers surveyed do not have any basic user skills, do not own any handheld electronic devices, lack information about those resources which they could use, and do not fully realize the benefits of digitizing their own professional activities.

Based on the data obtained at the first stage of the research, decision was taken on the need to organize technical training of computer skills for social workers. This process had a number of difficulties primarily related to homework due to the simple fact that this category of citizens did not have personal computers.

Following the completion of training that was organized for social workers, a repeated survey was conducted which was aimed at determining the level of preparedness of social workers for the use of electronic resources. In the following we will present the comparative data of respondent responses before and after training.

The data presented in Table 5 show that social workers' awareness of electronic resources that are relevant for their professional activities has increased greatly after training, and they started using them in the provision of social services to clients. The number of respondents who do not use any electronic resources at all in their activities has decreased after training from 70.2 to 5.7%; this being said, those respondents who still do not use electronic resources mainly fall within the age group of above 55. These respondents find it more difficult to acquire user skills; they feel more anxious and insecure when working with electronic devices, so additional support from the curator is needed to ensure that these social workers start using electronic resources in their professional activities.

Table 5 Distribution of respondent responses to questions about the use of electronic resources

Electronic resource	Response rate (%)	
	Before training	After training
I don't use them	70.2	5.7
Public Services	17	80.8
Electronic Registry	7.5	42.3
Data processing centers of the housing and utility sector and fuel and energy sector, Gazprom Mezhregiongaz, Volgogradenergosbyt	3.8	39.6
Website of the Pension Fund of the Russian Federation	1.5	18.1
Website of the Multiservice Center	0	21.5
Website of the Social Protection Committee	0	7.2
Federal Register of Disabled Persons	0	5.3

Source Compiled by the authors

The number of requests to the website of Public Services has increased from 17 to 80.8%. Social workers use this information resource to record clients' appointments at the doctors', pay utility bills, apply for sanatorium and spa treatment, receive services to provide disabled persons with convalescent facilities, etc. The number of respondents who access the website of Electronic Registry while providing services to clients, has increased from 7.5 to 42.3%. This resource allows social workers to make an online appointment at the doctors of various specialties for elderly people and disabled persons. The use of websites of the data processing centers of the housing and utility sector and fuel and energy sector, Gazprom Mezhregiongaz Volgograd, Volgogradenergosbyt—information resources that make it possible to transmit indications of metering devices for charging utility bills, has become more frequent as well (before training, it was pointed out by 3.8% of respondents, after training, it was pointed out by 39.6% of respondents). The number of respondents who access information resources the content of which is directly related to specifics of their activities and categories of clients, has increased: website of the Pension Fund of the Russian Federation (from 1.5 to 18.1%), Multiservice Center (from 0 to 21.5%), Social Protection Committee of the Volgograd Region (from 0 to 7.2%), Federal Register of Disabled Persons (from 0 to 5.3%).

Therefore, survey findings show that the degree of awareness of information resources that are relevant for professional activities has significantly increased among social workers after training, and they have started using them in their practical activities much more frequently.

The data presented in Table 6 show that almost one half of social workers surveyed (49.1%) after training claim the lack of difficulties of using electronic resources in their professional activities. This result is both due to the increased level of user skills of respondents after the training and the increased level of their awareness of applicability of electronic resources in the provision of social services to clients.

Table 6 Distribution of respondent responses to questions about the difficulties of using electronic resources in professional activities

Category of difficulties	Response rate (%)	
	Before training	After training
Poor computer skills	76.6	7.9
The lack of a personal tablet or any other mobile Internet-enabled device	55.1	17
Social worker's lack of knowledge about what resources to use and how they can be used	52.8	6
Psychological unwillingness of clients to use electronic resources while interacting with a social worker	19.6	15.5
Concerns about the additional workload due to the digitization of activities	10.6	4.5
No difficulties	0	49.1

Source Compiled by the authors

After the training, the number of respondents who indicate their poor computer skills decreased significantly (from 76.6 to 7.9%). That said, social workers who still face these difficulties, mainly belong to age group of above 55. The lack of a personal electronic mobile Internet-enabled device was pointed out by 17% of respondents, whereas at the first stage of the research there were 55.1% of them. This change is not due training as such, but due to the introduction of computers in activities of social workers.

The lack of awareness of possibilities of using information resources was demonstrated by 6% of respondents (the percentage of such responses was 52.8% before training). This result suggests that despite training there is a need to provide social workers with reminder cards containing the up-to-date list of websites that are necessary for their professional activities.

The smallest change in respondent responses compared to the stage before training was due to psychological unwillingness of clients to use electronic resources. No focused effort was made to accustom elderly people and disabled persons to the fact that social workers who provide services to them will be using electronic devices. In this regard, it is crucial to prepare social workers for interaction determined by the opposition of clients and their psychological support, in process of training.

Concerns about the additional workload due to the digitization of activities of after training was expressed by 4.5% of respondents (before training, there were 10.6% of such respondents). Additionally, some social workers have technical issues of using electronic devices: support from their curators will make it possible for them to feel like more competent in future.

Findings presented in Table 7 show that after the training, the number of respondents who claim the lack of benefits of using electronic resources in professional activities, decreased significantly (from 58.8 to 9.1%). Moreover, social workers (74.7% of respondents) cite time saving as the main digitization opportunity. This

Table 7 Distribution of respondent responses to questions about the benefits of using electronic resources in professional activities

Category of opportunities	Response rate (%)	
	Before training	After training
Lack of benefits	58.8	9.1
Saving the time of a social worker	24.2	74.7
Preservation of own resources of a social worker (physical, emotional, etc.)	9.1	16.7
Improving the efficiency of service provision	7.9	14.3

Source Compiled by the authors

increased indicator is due to faster execution of user operations by social workers for solving their job tasks as a result of improved skills of working with electronic devices. There has also been a slight increase in the preservation of own resources (from 9.1 to 16.7%) and an increase in the quality of services provided (from 7.9 to 14.3%). We believe that further accumulation of experience of using electronic resources in professional activities will contribute to the realization of additional digital opportunities by social workers.

4 Conclusions

Hence, the research results form the basis for establishing training for social workers at the premises of care-giving institutions. This support is aimed at identifying and compensating for the lack of competencies related to mastering information and communication technologies and using them in professional activities. In view of the foregoing, inference should be drawn that the suggested solution is innovative and can be used in future, since currently the project "Tablet Computers for Social Workers" has started in several regions of the Russian Federation, which allows solving a number of problems: (a) execution of reporting documentation of an employee in electronic form (journal, report, etc.); (b) electronic presentation of public services (for example, registration on the web portal of Public Services); (c) showing socially important information via Internet resources (for example, video clips on safety rules).

Innovations in the Retail Payment Market of Russia

Olga M. Korobeynikova, Dmitry A. Korobeynikov, Larisa V. Popova, Marina V. Glazova, and Ekaterina V. Kuzmina

Abstract The purpose of the research is to identify the main innovative trends in the development of the Russian retail payment market. The novelty of the study: (1) the justification of modern trends in the Russian retail payment market, which determine innovative transformation; (2) classification of forms of transformation of the Russian retail payment market. *Design/methodology/approach*: The study applied theoretical, empirical, general logical methods of scientific knowledge, which allowed to identify and justify the directions of innovative development of the payment market according to the following criteria: forms of identification of the account holder; account access forms; forms of initiation of the operation; technology operations. *Results*: The authors highlighted the features of the Russian payment market: close relationship with the financial technology market; increasing investments in such FinTech startups as lending sites, remote digital channel services and omnichannel interaction, payment systems, instant (quick) payment systems, personal finance management and biometric identification; Bank of Russia regulation of both the traditional payment market and the FinTech market; the incompleteness of the processes of quantitative and qualitative transformation of the market, which appears in a reduction in the number of banks with an increase in the number of accounts in credit organizations and the number of money transfers in accounts. The main subjects of the

Russian retail payment market are: money transfer operators (these include payment aggregators and credit organizations); electronic money operators (these include banking and non-bank credit organizations). The subjective transformation of the retail payment market is manifested in the fact that traditional credit organizations are supplanted by innovative entities, which contributes to increased competition in traditional segments and increased market efficiency. *Conclusions*: The highlighted features are involved in the generation, acceleration and transmission to users of innovative forms of payment transactions: forms of identification of the account holder (biometrics); forms of access to the account (tangible and intangible information carriers); forms of transaction initiation (QR codes, contactless payments); transaction technology (Real-time payments).

1 Introduction

The payment market is the most widespread segment of the financial market, since each economic transaction is accompanied by an urgent or deferred payment. If the wholesale payment market is characterized by large total payments and covers mainly large economic entities, then the retail payment market is the most massive segment of financial services by quantity. Payment turnover of the retail market covers a wide range of people, retail, economic entities and government agencies in the course of payment interaction with private individuals. The retail payment market is characterized by massive and regular payments of small amounts.

The payment market as a part of the financial market is a leader in diffusion and acceleration of innovations—technical, technological, infrastructural and others. Digital innovation currently dominates the payment industry and finance in general. The retail segment of the payment market, to a greater extent than the wholesale, is able to effectively innovate in the economy. The positive effect of introducing any innovation in the retail market is more noticeable and tangible for the mass consumer and, therefore, useful for society as a whole. The effect of mass retail innovation stimulates the development of the innovative environment of society and the economy. In this regard, the research topic is important and relevant.

The aim of the study is to identify the main innovative trends in the development of the Russian retail payment market.

The novelty of the study is due to:

1. the rationale as modern trends in the Russian retail payment market, defining the features of innovative transformation as digital: close ties between the payment market and the FinTech market, a high level of state regulation and

state participation in innovations, quantitative and qualitative dynamics of digital transformation;
2. the creation of a classification of forms of innovative transformation of the Russian retail payment market according to the following criteria: identification of the account holder, access to the account, technology for initiating the operation, technology for making the transaction, which made it possible to identify changes in the market as systemic.

2 Materials and Method

The theory and methodology of money circulation, payment markets, payment services, and payment infrastructure were considered in the works of Russian and foreign scientists and practitioners: [6, 8, 16], etc. Moreover, innovations and innovative technologies were studied [5, 10, 17], etc. The conceptual issues of retail consumer markets and the social significance of retail services in Russia are devoted to Morozova and Kabanov [11], Shakhovskaya et al. [13], and Skokov [14, 15]. Sectoral aspects of the innovation of finance and payment markets were developed [1–3, 7], etc.

An analysis of the works of modern scientists has shown that only foreign studies are devoted to financial innovations in the retail payment market [4, 9, 12], Russian scientists pay insufficient attention to these issues. The unified structure of the payment market as a segment of the innovative financial market is not presented, the patterns of its development in the digital economy are poorly studied. In fact, a situation lags behind theoretical research and analytics from practice. Modern innovations in the payment market are mainly innovations based on developments provided by the IT sector. Specialized scientific research in the IT field does not affect the specifics of the financial sector and the payment market. Thus, in modern science, there is insufficient theoretical interdisciplinary research on the symbiosis of finance and IT, which is actively developing on a practical plane.

The study applied theoretical, empirical, general logical methods of scientific knowledge, which allowed to identify and substantiate the directions of innovative development of the payment market according to the following criteria:

- forms of identification of the account holder;
- forms of access to the account;
- forms of initiating the operation;
- technology for the operation.

The objectivity of the conclusions is ensured by the involvement of statistical data and analytical materials of the Bank of Russia.

3 Results

3.1 Modern Features of the Retail Payment Market in Russia

The modern Russian payment market is open, developing qualitatively due to its ability to adsorb innovations in the financial and technological sector, to test and implement them. Innovative trends inherent in the global payment market are equally characteristic of the Russian payment market, adjusted for its organizational and structural features. In particular:

(A) The modern retail payment market is closely linked to the financial technology market. The main part of investments in financial and technological startups in Russia falls on the following areas of the FinTech industry: payment systems, lending platforms (P2P and online lending), remote provision of products to customers in digital channels and omnichannel collaboration, instant (fast) payment system, personal finance management and biometric identification. In Russian practice, the main partner group for FinTech is banks: according to statistics, 75% of FinTech companies are focused on joint projects with banks. Successful high-tech startups have been developed in the leading banks for the development and use of innovations: Sberbank (the bank is a state corporation), Tinkoff Bank (one of the first Russian digital banks), Alfa Bank (the largest private Russian bank), Moscow Exchange, payment systems QIWI and Yandex.Money, etc., bringing the Russian market of financial technologies to a qualitatively new, competitive level.

(B) Both the traditional payment market and the FinTech market are regulated by the Bank of Russia. The Bank of Russia Department of Financial Technologies conducts financial market research and identifies opportunities for adaptation and use of promising technologies and innovations in individual market segments. A feature of the modern Russian financial market is a large share of state participation in the capital of the main backbone participants. This determines the ability of the state to influence the direction and quality of innovation development. The Bank of Russia conducts testing of financial and technological innovations through the FinTech Association (created by the Bank of Russia and involving the largest banks and controlled entities). On the FinTech experimental site, innovative digital platforms and financial services are created (for example, the Masterchain platform based on Ethereum distributed ledger technology), regulatory norms and standards are tested (for example, legislative norms in the field of cryptocurrencies are tested), interdisciplinary studies are introduced (for example, a single system identification and authentication), digital models of interaction between lenders and borrowers (crowdfunding, P2P and P2B lending) are tested.

(C) In Russia over the past ten years, there has been a quantitative and qualitative transformation of the payment market (Table 1).

Table 1 The main indicators of the infrastructure of the retail payment market in Russia (at the beginning of the year)

Indicators	2010	2015	2016	2017	2018	2019
Number of credit organizations, units	1,058	834	733	623	561	483
The number of accounts in credit organizations total, thousand units	505,106	753,438	788,976	825,372	883,695	922,269
The number of accounts per 1 resident, units	3.6	5.3	5.4	5.6	6.0	6.3

Source Compiled by the authors based on Bank of Russia. Statistics. Statistics of the national payment system. Key indicators of the development of the national payment system. URL: https://cbr.ru/statistics/psrf/sheet001/ (Дата доступа 20.10.2019)

The number of banks, the main subjects of the payment market, that provide money transfer services in the retail segment is reduced. From 2010 to 2019 as a result of the actions of the Bank of Russia to reorganize the banking system, the number of banks decreased from 1,058 units, up to 483 units. At the same time, the number of accounts in credit organizations and the number of money transfers on accounts are growing. The number of accounts opened to subjects of the Russian economy grew by 417,163 thousand units, or 82.59%. If in 2010 there were 3.6 open accounts for each resident, then at the beginning of 2019 per 6.3 residents there were already 6.3 accounts, of which 58.70% (i.e. more than 3) were active for transactions.

3.2 The Subjects of the Retail Payment Innovation Market

The main entities carrying out money transfers in the retail payment market of Russia are:

- money transfer operators are credit organizations (payment agents and payment subagents) and payment aggregators;
- electronic money operators—banking and non-bank credit organizations.

A qualitative transformation of the retail payment market is manifested in the fact that traditional credit organizations of the first group are supplanted by innovative entities of the second group. The niche of traditional payment service providers—banks—is actively occupied by non-banking structures—mobile operators and electronic wallet operators. They are the leaders in the generation of payment innovations. The ongoing transformation of supply in the market gives rise to the highest competition against the background of high rates of changes. Competition is manifested on the part of banks in expanding the product line, loyalty systems, and on the part of electronic money operators in expanding market status, complementing their own functions with the issuance of payment cards and the provision of payment services

on a client base and infrastructure comparable to similar services of banks (or wider banking services).

In our opinion, increased competition in the electronic payments segment will lead to an expansion in the range of alternative payment methods for end users, to an increase in the speed of payments, and to a reduction in the cost of processing payments and the size of commissions. Competition will serve as an incentive for the development and implementation of symbiotic payment innovations at the junction of segments, during which new segments and markets will form. We believe that the result of competitive interaction in the payment market should be an increase in the efficiency of payments in the retail segment, ensuring the competitiveness of traditional payment systems on an innovative digital basis, as well as their financial and economic security [2, 3].

3.3 Innovations in Payment Tools and Technologies

Innovations in the payment market also affected the payment toolkit as a means of customer access to the account and transaction. We single out the most promising and popular innovative forms.

(A) Forms of identification of the account holder—biometrics.

Since mid-2018, the Bank of Russia, together with commercial banks, has been developing and introducing a unified biometric system based on technology for identifying users by voice profile and photo image. According to the authors, the introduction of biometric identification practices makes it possible to standardize and unify payment processes, reduce money and time costs for transactions and can become a step on the path of diffusion of innovations in various sectors of the economy and social sphere.

The widespread introduction of biometrics in the future will allow us to move to a new stage of customer-oriented development of payment services—the organization of phygital services (symbiosis of physical + digital). In phygital offices, recognition of the client's personality and needs will be carried out at the entrance to the office using a smart phone and facial biometrics. The consumer will be offered individually oriented services in accordance with his profile data; receipt of services is authorized by biometric methods. Testing of the innovative approach to payment services is carried out in one of the largest non-state Russian banks—Alfa-Bank, which plans to equip 100% of offices with technology by 2022–2024.

(B) Forms of access to the account—material card and non-card media, virtual media.

There is a certain eclecticism of account access tools on the market, but despite the emergence of virtual media, new instrumental form factors (rings, key rings, etc.),

Table 2 Main indicators of the card segment of the retail payment market in Russia (at the beginning of the year)

Indicators	2010	2015	2016	2017	2018
The number of card accounts of individuals, thousand units	125,787	226,967	242,877	253,149	268,531
The number of operations on cards of individuals, million units	3162	13,085	17,819	23,915	32,173
The amount of transactions on cards of individuals, billion rubles.	12,597	39,707	48,998	60,844	74,955
including cash withdrawal	10,891	23,955	25,932	25,717	26,602

Source Compiled by the authors based on Bank of Russia. Statistics. Statistics of the national payment system. Transactions performed on the territory of Russia and abroad, using payment and credit cards issued by credit organizations and the Bank of Russia, by type of customer. URL: https://cbr.ru/statistics/psrf/sheet014_1/ (access date 10/20/2019)

card payment tools are not being squeezed out of the market and are still a growing segment of the payment market.

The Bank of Russia data shows the growing popularity of card payment and settlement instruments in the retail market, despite the advent of non-card tangible and intangible instruments (Table 2).

Card accounts of individuals for 2010–2018 showed an increase of 142,744 thousand units, or 113.48% (about 1 unit for each resident of Russia). The use of maps was characterized by the following indicators. The amount of transactions with individual cards for the period increased from 12,597 billion rubles in 2010 to 74,955 billion rubles in 2018 (an increase of 5.95 times). The number of transactions using cards of individuals has increased to a greater extent—from 3,162 million units, in 2010 to 32,173 million units in 2018 (an increase of 10.17 times). The outstripping dynamics of the quantity compared with the sums of transactions confirms the conclusions made earlier by the authors about the massiveness of the retail segment of the payment market. Also given data indicate the continued popularity of traditional card tools.

(C) Forms of initiating operations—QR codes, contactless payments.

In addition to innovative technologies, tools and forms of payment in the payment market of Russia, such a tool for authorizing payment is proposed as QR coding. The technology is auxiliary and facilitates the introduction of payment data. For various reasons (infrastructural, technical, psychological and others) in Russia, it has not yet gained wide popularity among users, as, for example, in China. However, in our opinion, QR coding has great potential for distribution in retail, logistics, and social communications.

Contactless payments are a logical continuation, the development of contact payments due to more advanced methods of data protection and improved ergonomics for users. The contactless segment of the payment market is occupied by card carriers

(payment cards and loyalty cards), non-card material carriers (wearable devices—key rings, watches, bracelets, etc.), virtual carriers (mobile communication devices).

The most popular contactless payment tools are mobile Internet devices and mobile payment applications that integrate into banking ecosystems. According to the Bank of Russia, the number of contactless payment POS-terminals (NFC-readers) is about 25% of the total number of payment terminals, and this share is constantly growing. According to the global payment system Mastercard, Russian consumers for three years of industrial operation of payment services Apple Pay, Android Pay were able to take first place in the world in the use of these technologies. Only at the initial stage of operation of the Apple Pay payment service out of 1 million holders of Mastercard issued by Sberbank, 125 thousand customers (that is 12.5% of the total number of cards) were able to connect. During the first week of the operation of the Samsung Pay payment service, payment transactions with only one VTB24 bank made transactions worth 1.2 million Russian rubles. The increase in the penetration rate and the frequency of use of contactless technologies in the Russian payment market show their user preference compared to contact payment tools.

There has been intense competition between commercial banks and mobile operators in the contactless payment segment. If for the initial stage of development of mobile payments their average size was symbolic, then as the mobile Internet became more popular, the average size of contactless mobile payments reached 1035 Russian rubles (about $15) and went beyond paying exclusively for mobile services. Thus, increasing the cash flow of mobile payment services is stimulating Russian banks to transfer merchant acquiring networks to support contactless payments using mobile communication devices.

(D) The technology of the transaction—a system of quick (instant) payments.

Real-time payment technologies are an innovation that brings unconditional usefulness and obviousness to users, since it helps to accelerate money turnover and increase the efficiency of their use. Real-time payments are developing in the Russian market, which allow instant money transfers to be made with the account linked to the subscriber number of any telecom operator. Real-time payments are made regardless of the payment application of which financial institution the mobile subscriber uses. The development and implementation of real-time payments in Russian practice is carried out by the FinTech association affiliated with the Bank of Russia (a decentralized Masterchain platform for the exchange and storage of information based on distributed registry technology), to the infrastructure of which payment service providers are connected.

The innovativeness of the Real-time payment system is the versatility of tools and accounts for transactions regardless of the type of payment system. Transactions in the system are carried out in the formats: P2P/C2C and me2me-transfers for private clients, C2B, C2G. In the medium term, the Russian market plans to introduce an analogue of the Swedish Swish instant translation service, which will allow offering additional services through the opening of the API (OpenAPI), which will make it possible, in particular, to initiate a payment by a third party.

The quick payment system, on the one hand, forms an integral payment space and provides both an economic effect to participants and a public good to users. On the other hand, equal competitive opportunities are provided for joining participants in the payment market.

4 Conclusions

Thus, the Russian payment market has features: the retail payment market is closely linked to the financial technology market; the traditional payment market and the FinTech market are subject to regulation by the Bank of Russia; The Bank of Russia is actively involved in the generation of financial innovations and their diffusion of a financial market participant through the FinTech affiliate association; in Russia over the past ten years, there has been a quantitative and qualitative transformation of the payment market, which appears in a reduction in the number of banks, an increase in the number of accounts in credit organizations and the number of money transfers in accounts. The subjective transformation of the retail payment market is manifested in the fact that traditional credit organizations are supplanted by innovative entities, which contributes to increased competition and increased market efficiency.

On the market there is a generation, acceleration and transmission to users of innovative forms of payment transactions: forms of identification of the account holder (biometrics); forms of access to the account (information carriers); forms of transaction initiation (QR codes, contactless payments); transaction technology (Real-time payments), which gives reason to characterize the ongoing changes as complex.

Availability of Digital Financial Services: Problems and Solutions

Olga M. Korobeynikova, Dmitry A. Korobeynikov, Tatyana G. Agievich, Oksana A. Minaeva, and Svetlana J. Shaldokhina

Abstract *Purpose*: The aim of the study is to identify the main problems and limitations of the availability of innovative financial services and the search for possible solutions on the example of the Russian economy. *Design/methodology/approach*: Despite the intensification of scientific research and applied developments in the field of the digital economy, the problems of the wide availability of modern digital services for the population and economic entities, territorial imbalances, and improving the elements of the financial mechanism of systems that conduct digital innovations remain relevant. Applying theoretical, empirical, general logical methods of scientific knowledge and a systematic approach, the study identifies technical, regulatory, legislative, infrastructural, organizational, industry problems that impede the widespread use of innovative financial services, and suggests separate ways to solve them. *Results*: It was revealed that the problems under study are of a technical, legislative, infrastructural, organizational, and sectoral nature. To solve them, the authors propose an algorithm for combining industry ecosystems containing universal platforms and services. The algorithm includes 3 stages: the creation of innovative technologies in the economic and social spheres with the subsequent development and standardization of industry-specific digital competencies; Innovation of industry (financial) markets (payment, credit, insurance, securities market, precious metals market, etc.) and the creation of basic infrastructure platforms;

creation of a single digital environment, including compatible industry environments (institutional and infrastructure). *Conclusions*: Together, a single digital environment ensures the interaction of financial market entities and the development of infrastructure platforms and technologies; industry environments are merging into a single ecosystem of the digital economy. The proposed approach to the system formation of a single digital environment will contribute to the increase in the availability of digital financial services.

Keywords Digital economy · Finance · Financial market · Financial services · Digital technology

JEL Classification E51 · E71 · G21 · G24 · O33 · O35

1 Introduction

The digital economy can be useful to people, successful today and promising in the future, if the effects of scale and totality of its implementation are provided. Different areas perceive digital innovations differently. There are high-tech sectors of the economy that are producers and accelerators of digital innovation, but there are also traditional, analog sectors that are primarily recipients who need both innovation and transmission mechanisms for digital innovation of activities.

The producers and accelerators of digital innovation should be not only companies in the telecommunications and other technology sectors that produce basic equipment and technologies, but also companies in the financial sector. Their ability to accelerate and bring digital innovations to end users is determined by the fact that the financial sector provides the most mass, regular products and services (payment, credit and deposit, insurance, investment, etc.) to the general public and organizations of the real sector of the economy. It can be argued that it is the financial sector that sets innovative standards for mass service.

For their part, consumers place high demands on the innovativeness of financial services, demonstrate growing digital needs and thereby stimulate competition.

The offer of digital services, including financial, is interested in maximally satisfying the growing needs, however, there are a number of limitations not only of technological, but also of legislative, infrastructural, organizational nature, which restrict the availability of financial services and the development of the digital economy.

The purpose of this study is to identify the main problems and limitations of the availability of innovative financial services and the search for possible solutions on the example of the Russian economy.

The novelty of the study is provided by the following:

1. identifying and grouping the problems of limiting the availability of innovative financial services: technical, legislative, infrastructural, organizational, sectoral, based on, according to the authors, the underlying problems of socio-economic and political development of the country;

2. developing an algorithm for combining industry ecosystems that contain universal platforms and services and includes 3 stages: the creation of innovative technologies in the economic and social spheres; Innovation of industry (financial) markets and the creation of basic infrastructure platforms; creating a single digital environment. The proposed algorithm will ensure the interaction of financial market entities on an innovative basis.

2 Materials and Method

The ideas of the digital economy have long attracted the attention of scientists, businesses, states and users of digital services around the world. There is an understanding that the countries that have achieved the greatest success in this area will not only increase the economic and social effects within the state, but also strengthen their competitive positions in the global economy [3]. In different countries, the ambitious tasks set are more or less successfully solved [17].

The issues of theory and methodology of financial markets, financial infrastructure and financial services were considered in the works of foreign and Russian scientists [1, 2, 7], etc. Some aspects of digitalization of the economy, Digital innovations in financial services were developed [4, 5, 10] and others. The problems of regional economy, spatial development, stimulation of economic growth of territories, the search for its accelerators and innovation growth points were studied [8, 9, 11–15], etc.

Scientific and technological progress in the field of engineering and information technology has intensified applied financial research. Science and practice develop and test innovative technologies—artificial intelligence, neurotechnologies, quantum technologies, etc. Based on innovative technologies, new forms, methods, methods, financial services and products are proposed to meet the growing needs of society and the individual. But solving common problems does not mean solving them in special cases. The problems of widespread, widespread accessibility of modern digital services to the population and economic entities, territorial imbalances, improvement of the elements of the financial mechanism of systems implementing digital innovations remain relevant.

Applying theoretical, empirical, general logical methods of scientific knowledge and a systematic approach, the study identifies technical, regulatory, legislative, infrastructural, organizational, and sectoral problems of the availability of digital financial services and suggests separate ways to solve them.

3 Results

3.1 Technical Problems and Their Solutions

For various reasons, the processes of digitalization of the economy in Russia are not of a total nature and mainly affect urban conglomerations with a high population density. Many financial services are still not sufficiently accessible not only for the Russian population living in remote rural areas, but also for economic entities operating in these territories. Of course, this situation does not contribute to the socio-economic growth of territories and entities. The reason for the low availability, in our opinion, is primarily the insufficient development of high-speed Internet networks. As the developers of the state program "Digital Economy of the Russian Federation" noted in 2017, at the time of the formation of the program, only 10% of municipalities met the requirements for digitalization established in the legislation of the Russian Federation. Aligning the socio-economic development of territories and increasing the availability of digital services, in our opinion, are possible due to the digital innovation of the main industries, which are regional drivers.

The financial industry has changed significantly in recent years due to an increase in the speed of innovation, which creates the conditions for the accelerated introduction of the digital economy in the financial sector, and then in the serviced market segments. We consider the diffusion property to be the key in the process of acceleration and transmission of digital innovations to non-financial market entities. We believe that companies in the financial sector that provide the most popular services to economic entities and the public should become agents of digital innovation in traditional, analogous sectors of the regional economy.

3.2 Regulatory and Legislative Problems and Their Solutions

The most pressing and controversial issue from the point of view of legalization and regulatory regulation are financial services related to cryptocurrencies and their circulation. Due to the supranational and cross-border nature of cryptocurrencies, formally, they are a widely available asset attractive for speculative investment due to the high price volatility. This determines the wide popularity and prospects of cryptocurrency circulation, but at the same time creates fundamentally new risk situations. On the one hand, any state is obligated to protect the interests of its citizens in the financial sphere; on the other hand, the state is obliged to guarantee the rights and freedoms of citizens. In fact, there was a situation where the cryptocurrency emission and turnover market objectively functions, but without the presence of a regulator in the traditional sense applicable to legal segments of the financial market.

Currently, developed countries are on the way to solving the problem of legalizing cryptocurrencies, individual countries issue cryptocurrencies secured by physical

assets, however, an unequivocal answer to cryptocurrency circulation issues has not been developed.

3.3 Infrastructure Problems and Their Solutions

In the digitalization of individual, primarily remote from the center rural areas and the increase in the availability of financial services, the key role belongs to regional financial institutions. The main regional financial organizations in Russia are universal commercial banks. In our opinion, it is important to maintain and develop the regional banking sector and regional financial infrastructure, creating conditions for increasing the availability of financial innovations. Not only state-owned corporations, large industrial banks (Rosselchozbank, Gazprombank and others), but also small and medium-sized regional banks that are well acquainted with the conditions and characteristics of economic activity in a certain territory are able to fully satisfy the demand for financial services of regional business entities in Russia. Regional commercial banks act as subjects of the financial system as its full-fledged infrastructure elements, provide regional clients with equal access not only to national, but also international financial instruments, products, services, and services.

At the same time, the Bank of Russia, pursuing a policy of improving the financial sector, is reducing the number of small and medium-sized regional banks. For example, in 2010, 5 regional banks were registered in the Volgograd Region (with a total number of banking system institutions in the region of 716 units), and by the end of 2019, there was only one local bank, NOKSSBANK, a bank for the development of oil and gas production, conversion, and shipbuilding and construction [6] (the total number of banking system institutions in the region as of 01.07.2019 decreased to 515 units). According to the Bank of Russia, the leaders in the number of banks registered in the region as of July 1, 2019 are Moscow and the Moscow Region (238 units), St. Petersburg and the Leningrad Region (28 units), the Republic of Tatarstan (17 units).

The ongoing processes are also caused by the displacement of traditional forms and channels of banking services by innovative forms [16]. Financial institutions are moving from multichannel to omnichannel interaction. To equalize the regional imbalance and solve the problems of accessibility of financial services, the state significantly expanded the functions of the FSUE Russian Post, created a specialized Post Bank, and digitalized postal channels.

3.4 Organizational Problems and Their Solutions

The organizational aspect of the problem of accessibility of financial services is that there is no single digital environment and a single ecosystem of the digital economy. Separate digital platforms and services are actively developing and competing among

themselves, as a result of which private current needs for financial services are satisfied. Obtaining comprehensive services, especially inter-sphere services (for example, inter-budget services, commercial services with state identification), in a single digital environment is in most cases impossible. To solve the problem, we offer the integration of private (industry) ecosystems containing universal platforms and services into a single digital ecosystem. Diffusion of financial digital innovations in industries and sectors of the economy can occur on the basis of adaptation of platforms and technologies, on the basis of which general and specific competencies are formed for the development of industry markets.

3.5 Sectoral Aspects of the Problem and Their Solutions

The problem of sectoral imbalances in development has been relevant for a long time. In Russia, sectoral problems are often superimposed on the problems of territorial imbalances. An example of this is agriculture, which is least digitalized of all economic spheres.

Agriculture in Russia is carried out on an area of 17.1 million km^2 in five climatic zones with different climatic, demographic, infrastructural, social and other conditions. According to the Federal State Statistics Service, 17,480 rural settlements are home to 25.43% of Russia's population. Agriculture is a traditional (non-digital) sector of the economy that comprehensively uses land, labor and material resources to ensure food security of the state. Despite the traditional nature of the rural structure, productive forces and industrial relations in agriculture, it needs not only technological, technical, but also financial innovations produced by the symbiosis of the financial and IT sectors. The tendencies to a decrease in the physical presence of banking and other financial organizations in the peripheral territories with respect to the federal center, noted earlier in Sect. 3.3, confirm the relevance of innovative methods and mechanisms for increasing the availability of digital services for the population and economic entities working in rural areas (in relation to the peripheral territories about the problems of accessibility not only of digital financial services, but also of various other digital services).

Innovative digital technologies in the modern world are recognized as key drivers of economic growth, which can be achieved through the transformation of traditional business models of the so-called "analogue" economy. According to the authors, end-to-end digital technologies can find application in the following non-digital areas of agribusiness and thereby increase the availability of financial and other services for agribusiness entities and the rural population:

- Cloud technologies allow to place arrays of archive information outside the own information circuit, reducing the cost of storing and transmitting information without losing data security. In agribusiness, this can be not only financial information, but also technological information about the state of land, material, labor, financial resources, the dynamics of crop yields, animal productivity and so on.

The availability of storage capabilities for large archival data forms an array of big data and opens up prospects for their most informative processing.

- Technologies for working with big data provide the highest level of generalization and analysis of information, which is important for predicting future overall performance, crop programming, predicting animal productivity, environmental control, building logistics supply chains of resources and sales of manufactured products, etc.
- Artificial intelligence and robotics not only release human resources from low-skilled, labor-intensive, dangerous or unhealthy segments, but also significantly increase human productivity. In Russian agriculture, there is a problem of a shortage of labor resources in the most labor-intensive and non-prestigious areas of work, in work with conditions harmful to human health, at extremely low or high temperatures. Such areas of work primarily require robotics.
- Open interfaces and distributed registries are of interest in connection with the use of blockchain technologies for decentralization of operations, bypassing intermediaries. In agriculture, it is advisable to develop an industry-wide decentralized platform based on blockchain technologies to create a transparent base of product manufacturers (including organic products), resource suppliers, product processors, logistics centers, etc.
- Biometric processing of information helps to solve both the problem of the territorial availability of digital services for individuals and the task of optimizing operations in a geographically remote business. Unlike other innovations, the success of biometrics as a technology is determined not so much by technical and technological factors as psychological factors, namely the ethical acceptability of personal data collection for individuals. The use of biometrics for personal identification in the mass segment of financial and non-financial services is advisable only if the conditions for mass participation in the project are observed. If there are at least some number of refusals by individuals to transfer biometric data to databases, then this may become an insurmountable obstacle to the widespread dissemination of technology as a whole. However, biometrics can be used and be useful in the non-financial activities of agricultural producers for the qualitative identification of biological assets (productive and livestock, dong animals, etc.).

3.6 Algorithm for Creating a Unified Digital Environment That Provides Increased Access to Digital Services

To solve the problems posed, the authors propose an algorithm for creating a single digital environment that combines industry markets and industry environments (Fig. 1).

The algorithm includes 3 stages:

Stage I—the creation of innovative technologies in the economic and social spheres with the subsequent development and standardization of industry-specific

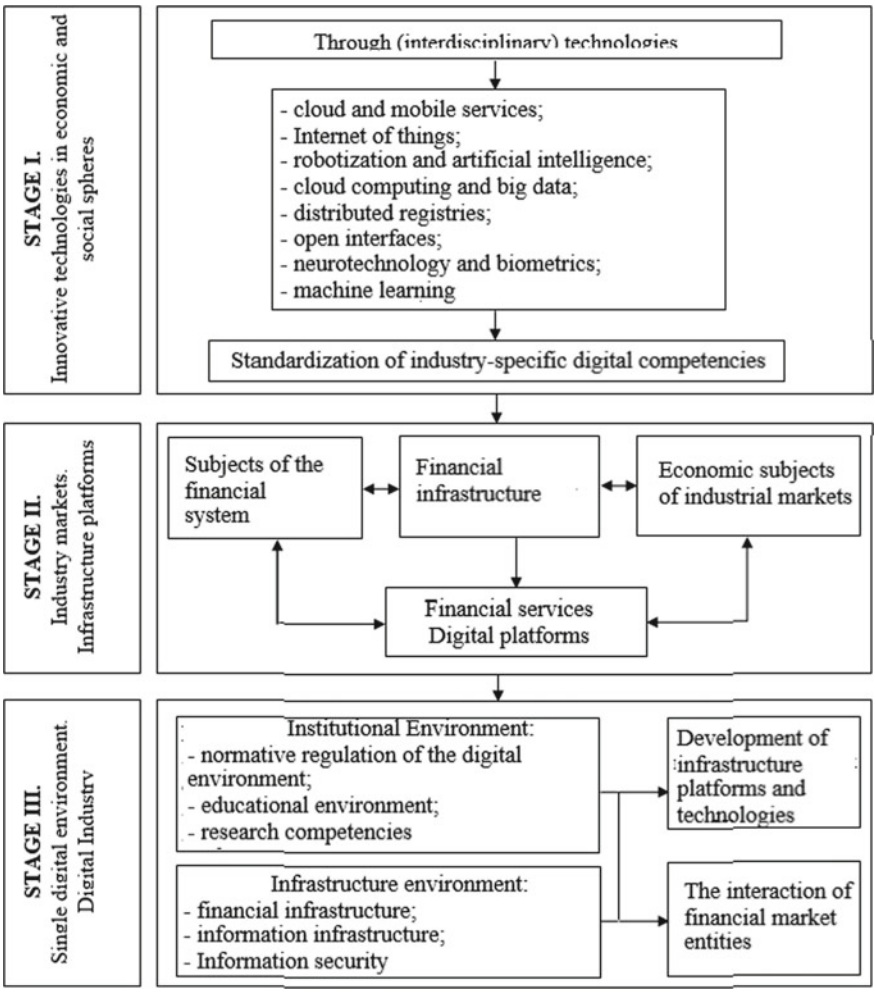

Fig. 1 The algorithm for creating a single digital environment. *Source* Developed and compiled by the authors

digital competencies. At this stage, it is necessary to create and implement interdisciplinary (cross-cutting) technologies, which are products of the symbiosis of IT-developments and industry-specific (financial) innovative developments. The presence and successful application of new industry technologies will contribute to the innovation of industry markets. At this stage, in our opinion, it is important to develop industry standards and standardize industry competencies. Financial companies engaged in large-scale digital development, bring unique digital platforms and services to the market, which are often not compatible with competitor technologies. As a result, closed digital environments are formed that are not integrated into a

single digital market environment. A particular effect is achieved for developers and owners of the platform, but there is no increase in utility across the market.

Stage II—the innovation of industry (financial) markets (payment, credit, insurance, securities market, precious metals market, etc.) and the creation of basic infrastructure platforms. The presence of platforms allows to create innovative financial services.

Level III—a single digital environment, including compatible industry environments. The institutional environment should develop in three areas: regulatory regulation of the digital environment; educational environment; research competencies.

The infrastructural environment should develop in the following areas: financial infrastructure; information infrastructure; Information Security.

4 Conclusions

Thus, a study of the problems and limitations of the availability of innovative financial services on the example of the Russian economy showed that they are based on the underlying problems of the country's socio-economic and political development. The main problems are technical, legislative, infrastructural, organizational, and sectoral in nature.

To solve the identified problems, the authors propose a conceptual algorithm for combining industry ecosystems that contain universal platforms and services and includes 3 stages: creating innovative technologies in the economic and social spheres; Innovation of industry (financial) markets and the creation of basic infrastructure platforms; creating a single digital environment. The proposed approach to the system formation of a single digital environment, presented in the developed algorithm, will contribute to the increase in the availability of digital financial services in both the territorial and operational aspects.

Distributed Registries for Credit Cooperation: The Need and Opportunities

Olga M. Korobeynikova, Dmitry A. Korobeynikov, Mariya I. Kuzmina, Aleksandr V. Malofeev, and Svetlana A. Shevchenko

Abstract *Purpose*: The purpose of the research is to study the feasibility and possibilities of using distributed ledger technology in credit cooperation. *Design/methodology/approach*: The research methodology is based on traditional cooperative principles: mutual assistance, solidarity, transparency, trust, democratic management of the cooperative. This study aims to strengthen and comply with these principles as ensuring the identity of credit cooperation in the financial market. In the work, methods of forecasting and SWOT analysis are applied. *Results*: The feasibility of using distributed ledger technology in the practice of credit cooperation is determined by the following. It is necessary to innovate cooperative services and strengthen the specific inherent features of cooperation, which are expressed in the basic cooperative principles. The most effective innovation for credit cooperation may be the technology of distributed registries (blockchain). The use of distributed ledger technology in credit cooperation will provide the following opportunities. Multilevel distributed control of cooperative members will be strengthened. Members of a credit cooperative will have the opportunity to control the integrity of the chains and the formation of new links. For the market regulator and self-regulatory organizations, access to the registry is open for regulated supervision and monitoring activities. To assess the possibility of using the technology of distributed

registries from the point of view of the state of the external and internal environment, the SWOT analysis method was applied, which confirmed the possibility and necessity of using distributed registries. *Conclusions*: According to the authors, the use of distributed ledger technology in credit cooperation is advisable. The technology is able to enhance competitive advantages based on cooperative principles. The blockchain will provide a more perfect exchange of information between shareholders about the formation and use of a common cooperative fund. The technology can increase the transparency and controllability of operations, avoiding external mediation. A distributed registry in credit cooperation can be the best practical solution to strengthen the community of members, enhance transparency of activities, and increase the efficiency of the use of funds in the common interests of members.

1 Introduction

Credit cooperation in the world has a long history dating back to the ideas of F. H. Schulze-Delitzsch and F. W. Raiffeisen. Over the past centuries, it has developed unique principles of activity, occupied its own niche of socially oriented financial services for the most vulnerable people, absorbed the national mentality of the served peoples, became a full-fledged segment of the financial market, acquired resistance to individual risks or developed ways to protect against them.

Despite the fact that credit cooperation is a traditional niche form of financial services, it is increasingly approaching banks in terms of the range of services and products, as well as their sales. Cooperative banks, being the most developed form of credit cooperation, are not inferior to non-cooperative banks in market positions. To preserve not only the achieved competitive positions, but also the cooperative values tested by time, a search for new, innovative solutions is required.

The development of engineering and technology in recent years has led to increased interest in the use of digital innovation in various fields. In particular, the opportunity has arisen for the practical application of distributed ledger technology. For credit cooperation, it is of interest from the point of view of additional opportunities for observing cooperative principles and maintaining cooperative identity, which determines the relevance of this study.

The purpose of the study is to study the feasibility and possibilities of using distributed ledger technology in the practice of credit cooperation.

The novelty of the study is provided by the following:

1. it is proved that the development of credit cooperation in modern Russia is hindered by a systemic violation of the basic cooperative principles (mutual

assistance, solidarity, transparency, trust, democratic management of the cooperative), which is manifested in abuses of the executive bodies of cooperatives, bankruptcies and is confirmed by statistics from the Bank of Russia;
2. it was proposed to use distributed ledger technologies to innovate borrowing and savings operations, income and expenses of cooperatives in order to preserve cooperative self-identity, preserve a occupied niche of microfinance services and ensure the implementation of cooperative principles (especially in terms of transparency, democratic management and control).

2 Materials and Method

Modern aspects of the theory of credit cooperation have been studied by scientists [4, 5, 16] and others. Credit cooperation is an integral part of a socially oriented economy, fulfilling the most important mission of improving human life, financial support and mutual assistance. Extended views on the problems of a socially oriented economy are presented in the works [11, 12, 15] and others.

The financial aspects of credit cooperation and related issues of corporate and personal finance were studied [1, 3, 6, 8, 13] and others. The transformations of the economy caused by digital innovations were studied by scientists [10, 14] and others. Finances, which are the most flexible and receptive sphere to technological innovations, were the object of study in work [7]. Of interest is the work [2] devoted to current trends in the development of blockchain technology.

However, special studies on the application of financial innovations in the credit-cooperative sector of the financial market in the world and in the Russian scientific literature are not enough. Mostly the general issues of improving cooperative activities have been studied [9], but the application of technological innovations in the industry aspect has not been studied enough.

The research methodology is based on traditional cooperative principles: mutual assistance, solidarity, transparency, trust, democratic management of the cooperative. This study aims to strengthen and comply with these principles as ensuring the identity of credit cooperation in the financial market. In the work, methods of forecasting and SWOT analysis are used to assess the possibility of using distributed ledger technology in credit cooperation.

3 Results

3.1 Difficulties in Observing the Basic Principles of Credit Cooperation in the Modern Economy and the Need for Distributed Ledger Technology

With the development of IT-technologies, there is increasing competition between traditional financial intermediaries and technology companies in the financial market. These processes affect both national, regional, and global levels. The subjects of credit cooperation, in spite of the firmly occupied positions in microfinance services, are forced to approach more and more their functions to large financial intermediaries—banks, to unite on the principles of integration and collaboration. Traditional banks work with FinTech companies, or create divisions within FinTech. Thus, banks are reformatting their activities to digital interaction with customers, and in this they see prospects and opportunities for development. Threats to traditional financial intermediaries are carried out by high-tech companies, which on an innovative basis combine broad market functions, including credit, settlement, payment, savings and other functions of banks.

In order for credit cooperation to remain in the financial intermediation market and maintain its identity, according to the authors, it is necessary to innovate cooperative services and strengthen the specific immanent features for which they are chosen by shareholders.

The specific features of credit cooperation are expressed in cooperative principles: mutual assistance, solidarity, transparency, trust, democratic management of the cooperative.

The principle of mutual assistance shows the existence of special ties between members of the cooperative, which give confidence to shareholders in receiving financial assistance. The principle of solidarity is revealed through shared responsibility for the results of the cooperative. The cooperative principle of transparency means accountability on the part of each member. The cooperative principle of trust means the possibility of obtaining mutual financial assistance in cases where its attraction from other sources is impossible. Democratic governance implies the equal participation of all members in decision-making.

However, in modern economics and society, basic principles are often violated. So, the principle of trust is losing relevance due to the growth of the scale of activity and the expansion of the community of shareholders, who are only formally, upon the fact of making share and membership dues, are a community, but do not have personal connections. That is, there is no individual control and moral responsibility. The principle of transparency is violated automatically if the principle of trust is not respected: the absence of commonality of shareholders bound by moral and other intangible obligations leads to abuse by executive and audit bodies. The principle of mutual assistance is replaced by a natural desire to earn big profits on alternative operations and by diverting funds to such operations. As a result of violation of the

principle of democratic governance as a consequence of the above principles, abuse of executive bodies and bankruptcy of cooperatives occur.

Examples can be seen in credit cooperation in Russia. According to the Bank of Russia as of the 4th quarter of 2019, with the total number of active credit cooperatives of citizens 1,557 units and 700 units of existing agricultural credit cooperatives, 515 units and 192 units were under reorganization respectively. In total, the Bank of Russia recorded 6,893 credit cooperatives of citizens and 1,970 agricultural credit cooperatives in Russia. These data indicate a crisis of compliance with basic cooperative principles.

The ideas of credit cooperation, according to the authors, should have the right to life, they have proved this right with their own centuries-old history. But for this, credit cooperation should use the technological opportunities provided by the market to strengthen its competitive advantages. The most effective of modern innovations for credit cooperation may be the technology of distributed registries (blockchain).

3.2 Possibilities of Using Distributed Ledger Technology in Credit Cooperation

A distributed registry is a database that all members of a cooperative that are members of the network have access to through an identical, private copy of the registry. The distributed database of the credit cooperative should contain information on the status and movement:

- liabilities of the cooperative (mandatory and optional contributions of members of the cooperative, passive settlements with shareholders and third parties, other liabilities);
- assets of the cooperative (non-current property, funds issued to shareholders, active settlements with shareholders and third parties, other assets);
- income and expenses of the cooperative, executed in accordance with the estimate, which is approved by the general meeting of members of the cooperative (Fig. 1).

As it is shown at Fig. 1, all cooperative operations with members and third parties are linked in chains, where each link confirms the existence of linked links. The set of operations with liabilities and assets makes up a single shell and is fixed in the blockchain. Any change in the registry in real time is reflected in all copies of the registers and therefore is transparent both for the controlling bodies of the cooperative and for each member. Security and reliability of transactions is ensured by cryptographic methods of protection—keys and electronic digital signature.

The technology provides multi-level distributed control of cooperative members. Members of a credit cooperative (shareholders) will have the opportunity to control the integrity of the chains and, if necessary, the formation of new links—the movement of assets and their sources. This ensures internal control of all activity parameters and the implementation of cooperative principles. Authorization of the

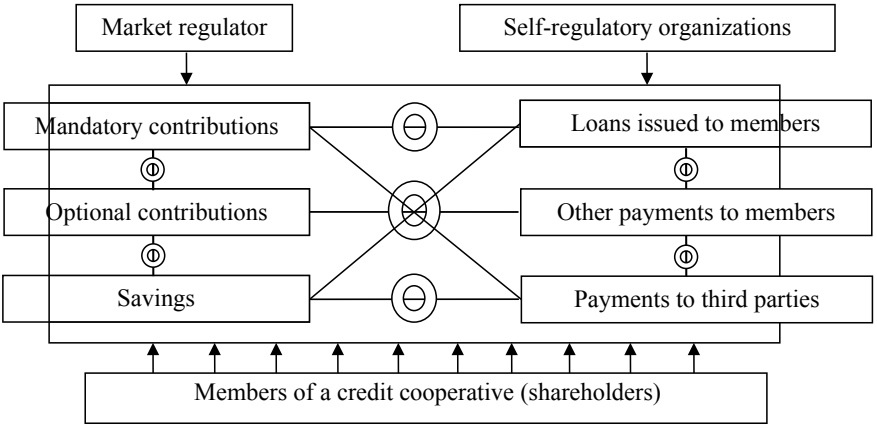

Fig. 1 Conceptual scheme (fragment) of using distributed ledger technology in a credit cooperative. *Source* Developed and compiled by the authors

execution of operations must also be multilevel. For control purposes, access to the registry database should be open to every member of the cooperative. For external controllers—the market regulator and self-regulatory organizations—access is opened to the extent that it is necessary for regulated actions for supervision, monitoring and other things. All operations of a credit cooperative can be recorded in distributed registers in parallel with the existing accounting system, or separately from it, thereby increasing the efficiency of the existing system of accounting, control, analysis.

To assess the possibility of using the technology of distributed ledgers in credit cooperation from the point of view of the state of the external and internal environment, we apply the method of SWOT analysis (Table 1).

As the results of the SWOT analysis show, when using distributed registry technology in credit cooperation, external threats arise: isolation of the cooperative's distributed registry from external information systems, uncontrolled settlements with third parties, and the possibility of uncontrolled withdrawal of cooperative funds. At the same time, the technology being evaluated provides new opportunities for the transfer and storage of information, digitalization of assets (especially in terms of loans issued to members of a cooperative), liabilities (especially in terms of attracted savings of members of a cooperative), share capital, execution of an income estimate (in terms of charging and collecting interest loans granted) and expenses, intra-cooperative cash flow. The external environment reveals new opportunities that are associated with protection from external risks of unauthorized interference, compromise of data and illegal actions of third parties; with integration with distributed counterparty registries; with a reduction in settlement time and acceleration of the turnover of funds in the calculations. In the operations of a credit cooperative with securities, in loans to shareholders, in the assessment of mortgaged property, a distributed register

Table 1 SWOT analysis of the assessment of the possibility of using distributed ledger technology in credit cooperation

External conditions	
Threats	Opportunities
Isolation of a distributed registry of a cooperative from external information systems	Protection against external risks of unauthorized interference, data compromise and illegal actions of third parties
Uncontrollable settlements with third parties	Integration with distributed counterparty registries
Risks of uncontrolled withdrawal from a cooperative	Reduced calculation time and accelerating the turnover of funds in the calculations
Internal conditions	
Weaknesses	Strengths
Low financial and technological literacy of cooperative members	High potential for information transfer and storage
Weak infrastructural and technological accessibility of network forms of interaction	Strengthening cooperative principles
Professional incompetence of cooperative staff	Enhanced control function
	Reducing the time and money costs of transmitting information

Source Developed and compiled by the authors

will reduce transaction costs and the time it takes to transfer information from the moment a transaction is concluded to settlement.

Considering the internal environment of credit cooperation, we can talk about weaknesses that are personified or private in nature: low financial and technological literacy of the members of the cooperative; poor infrastructure and technological availability of network forms of interaction; professional incompetence of the cooperative staff. Strengths prevail over weaknesses and allow us to talk about the prospects of using technology in credit cooperation. They are: high potential for the transfer and storage of information; strengthening cooperative principles; strengthening the control function; reduction of time and money costs of information transfer.

4 Conclusions

Thus, the technology of distributed registries for credit cooperation can strengthen competitive advantages based on the cooperative principles of mutual assistance, solidarity, transparency, trust, and democratic governance. In the future, the technology of distributed registries will provide a more perfect exchange of information between shareholders on the formation and use of a common cooperative fund. The technology is able to increase the transparency and controllability of the operations

of a credit cooperative, while avoiding not only external mediation, but also the need to maintain internal control bodies (revision commission of a cooperative or similar). Better control over the financial activities of the cooperative will be ensured by the market regulator and self-regulatory organizations, which may be given the right to access the shared registry with encrypted personal data. Through ongoing monitoring, regulatory reporting requirements or compliance with industry standards will be more effectively implemented. A market regulator connected as an external node will be able to receive data on cash flow movements instantly, which will help simplify regulatory compliance procedures.

In addition to all the advantages of blockchain technology for credit cooperation at the initial stages of its use, one can expect some technical, organizational, legal, financial and other difficulties both within individual credit cooperatives and in cooperative regional and national associations. Nevertheless, according to the authors, a distributed registry in credit cooperation may be the best practical solution to strengthen the community of members, enhance transparency of activities, and increase the efficiency of the use of funds in the common interests of members.

Digital Marketing and Sales Technologies: Dealership Marketing Management

Victor Ya. Konks, Evgeniy V. Krasnov, and Ekaterina V. Sumarokova

Abstract Nowadays, for many Russian companies it is becoming increasingly difficult to attract the necessary number of client requirements and requests for sales and service. Often there is a problem of matching the level of the declared services and the company's ability to meet them. The problem lies in the need to develop optimal models for managing company capacity and resources. In a highly competitive market environment, the speed and accuracy of processing large volumes of data plays an essential role. This is particularly acute in the automotive business. According to various estimates, almost 80% of the marketing budget is invested in digital. Widespread introduction of digital technologies allows achieving a leading position in the market. The authors have made an attempt to highlight the problem of finding optimal solutions in the marketing management of the dealer center on the example of ROLF company, which showed high results against the background of market instability, being the leader of the Russian automotive business. Effectively working digital marketing tools and the results of their application are systematized and argued in the article: the need for the simultaneous using of various tools, technologies and software products; the need to use call tracking data on user behavior to form an effective advertising strategy; some queries, traditionally considered the most conversion ones, in practice are not; reduction of promotion costs is possible due to the redistribution of texts and landing pages. The question of what specific solutions and tools allow the company to grow steadily, work efficiently and achieve a leading position doesn't have a clear answer. But without the using of specific digital marketing and sales tools in the current environment is basically impossible. The recommended basic composition of the tools is proposed in the article.

1 Introduction

The article discusses the application of some new ways to measure, achieve and maintain business performance [1]. Ultimately, business performance is measured by comparing collected data, existing indicators, balance sheets and key performance indicators (KPI).

Business process optimization is a systematic approach that replaces resource-intensive efforts and improvements, and above all, it aims to innovate and achieve better results. Improvement of business processes allows to withstand structural changes in the company, which are necessary when introducing new technologies.

Factors affecting the efficiency of the business and its maneuverability are different. Some of these factors can be controlled and monitored, measured and interpreted: environment, market, legislation are constantly evolving and changing. The environment in which a significant event has occurred or is taking place provides the background and conditions that will be used as a basis for taking corrective actions for the business processes and marketing complex of the company [2].

We systematize efficiently working tools of digital marketing and sales technologies using the example of the marketing management of the holding of ROLF automobile dealerships.

2 Background and Methodology

The data storage and processing system developed by ROLF is valid for all areas of sales, service, support units and dealerships. All the data about customers, employees, communications and business processes is stored in it. Marketing and sales executives have the opportunity in real time to extract from it everything that is needed: any kind of analytics, statistics, indicators and results of operational activities [3]. This allows ROLF to be among the best in the automotive business for a long time.

The company uses classical tools and approaches in marketing and sales management. Their effectiveness is ensured by a wide implementation of the latest developments in digital technology to achieve a leading position in the market. Let's consider and analyze the structure and decisions in management of the dealer center of the company for the certain period.

Structure and solutions in the management of the holding and dealer centers, marketing and sales management. Marketing is an information and economic system aimed at effective promotion of goods/services from manufacturer/distributor

to consumer in order to maximize customer satisfaction and profit. Marketing in the Dealer Center is a tool for implementing the company strategy. Its main task is to provide effective tactics for achieving the set goals. How should the marketing service, motivation system and control of employees' work be organized?

The company works with global car brands of mass and premium segment: Hyundai, Mazda, Mitsubishi, BMW, Audi and many others. This makes the company diversify its approaches to marketing and sales management.

The basic directions of marketing activity in the Dealer Center: sale of new cars and cars with mileage; service and spare parts; the Dealer Center as a brand; clienting.

Marketing management is a functional part of the overall company management system, aimed at achieving the alignment of internal capabilities with the requirements of the external environment to ensure profit. What does Dealer Center marketing management include?

- Marketing team, motivation and control system, KPI for marketers.
- Processes/efficiency, control and immediate adjustment.
- Budgets ("what, why, where to and where is the result?").
- Price list and KPI.

Marketing is a way of thinking. What kind of marketer does a company need to be in order to help it achieve its goals? What kind of knowledge, skills and personal qualities should this specialist possess? First of all, this is the first line manager. Secondly, they must understand the business and how the Dealer Center earns. Thirdly, they should possess all marketing tools professionally and at a high level.

At ROLF, marketing faces the following challenges:

- Ensuring the necessary amount of quality traffic in the new car sales department, mileage department and service center to fulfill the plans of the departments.
- Ensuring correct statistics of traffic accounting and analysis.
- Efficient use of the marketing budget: reducing the cost of attracting customers and saving the budget allocated for marketing.
- Daily analysis of the current situation in the Dealer Center, competitive environment, market situation and quick reaction to changes.
- Competent communications with the importer in all areas of marketing: loyalty, quick coordination, no penalties for violations of communication standards, correct reporting, attracting financial resources to the Dealer Center by receiving bonuses and compensation.
- Increase in the number of repeat customers, purchases by recommendation (sales department of new cars and cars with mileage), an increase in the frequency of customer calls to the service, the average check and % of return of customers to the service center.

KPI for a marketer:

- Execution of the traffic plan (primary calls, Internet applications).
- Fulfillment of the target on budget/saving.

- Fulfillment of the sales plan (piece/realization of 30–40% of monthly income (variable part)).
- + quarterly bonus (if there are quarterly reports and a bonus component by type of activity).
- + annual bonus (budget savings on marketing + achievement of general goals of the Dealer Center).

KPI marketing of a dealership:

- The total amount of primary traffic (primary calls and visits, Internet applications).
- Marketing activity ratio (marketing revenue/cost)
- The cost of one primary contact (primary calls and visits, Internet applications).
- The cost of one contract.
- SR (Strike Rate).
- Local market share.
- Growth in the total number of clients in the database.
- Number of repeat customers and purchases by recommendation.

Marketing system management: marketing goals (sales, traffic, financial resources) are set; strategy for their achievement is developed; tactics are planned and implemented; analysis of results.

Dealer Center marketing complex [4–6]:

- Product (product policy)—brand, quality, style, features, reliability, service requirements, warranty.
- Price (pricing policy)—prices, special conditions at the counter sale, credit conditions.
- Place (sales policy)—location, coverage area, exhibition space, facilities.
- Promotion (promotion policy)—advertising, personal sales, public relations, direct marketing, sales promotion, merchandising, sponsorship.
- People (personnel)—the qualifications and appearance of staff.

The main concentration of marketing in the Dealer Center is promotion (the main traffic generator). We will consider this marketing tool in more detail:

ATL (above the line) is all mass advertising, in fact, all those where you pay for placement: TV, press, advertising in cinemas, outdoor advertising.

BTL (below the line) activities include sales promotion, PR, personal sales + packaging, merchandising, "special price" or "2 in 1" promotions, contests.

TTL (through the line) combines the two abovementioned directions, this type of promotion is considered to be a transition from "forced invasion of the territory of the consumer" to "readiness of the consumer to contact".

The company uses all possible metric systems that are on the landing pages of the company, these are Calltouch, CallKeeper, Calltracking and others. Tracking the consumer's paths to the Dealer Center, registering personal data, recording contacts and their contents, analyzing them and using them to continue contact even if there is no initiative on the part of the consumer—this is an "intrusion".

The justification for using such technologies can only be the desire to help the consumer. Such secondary contacts can be carried out only by specialists of a significantly higher level of those who have not been able to bring the first contact to a positive result. And here the company has an effective experience with failures.

PR (public relations) is the management of information flows between the organization and the public in order to create a positive image of the company in the minds of the potential consumer, as well as other stakeholders.

SMM (Social media marketing) is a process of attracting traffic or attention to a brand/product through social media. It is a set of measures to use social media as channels for promoting a company and solving other business tasks.

CRM is a model of interaction considering a client to be the center of business philosophy, and the basic directions of activity are measures to support effective marketing, sales and customer service. Support of these business purposes includes gathering, storage and the analysis of the information on consumers, suppliers, partners, and also about internal processes of the company. Functions to support these business goals include sales, marketing and customer support.

3 Discussion and Results

Sales funnel, setting KPI on traffic to marketers and calculating monthly targets:

Indicators	Jan	Feb	Mar	Apr	May	June	July	Aug	Sep	Oct	Nov	Dec
Dealer Center traffic	1,850	1,621	2,489	**2,511**	1,892	2,010	1,909	1,913	1,907	2,001	2,001	1,854
Sales (pcs)	214	169	**278**	**278**	206	222	210	210	210	220	220	204
Strike rate (%)	**11.6**	10.4	11.2	11.1	10.9	11.1	11.1	11.1	11.1	11.1	11.1	11.1
Prepayments (pcs)	296	217	357	**365**	266	288	273	272	272	286	285	265
Share of returns (%)	**27.7**	22.1	22.3	23.9	22.8	23.0	23.2	23.0	23.2	23.1	23.0	23.1
Strike rate (%)	**16.0**	13.4	14.4	14.6	14.1	14.3	14.3	14.3	14.3	14.3	14.3	14.3

Control and forecast of KPI on calls: primary calls, Internet applications, calls to the contact phone, plan and actual on calls for the day-month:

Brand	Dealer Center	Plan	Actual	% performance	Plan	Actual	% performance
		Month			Day		
Mitsubishi	Yug	948	955	**100.8%**	31	31	**100%**
Hyundai	Khimki	2,086	2,449	**117.4%**	67	79	**117.4%**

(continued)

(continued)

Brand	Dealer Center	Plan	Actual	% performance	Plan	Actual	% performance
		Month			Day		
Ford	Tsentr	1,364	725	53.1%	44	23	53.2%

How is the marketing budget planned and calculated?

Budget	January	February	March	April	May	June	Half year
SR (%)	15	15	15	15	15	15	15
Calls + online applications	353	540	693	**847**	673	840	3,946
Expenses per 1 contact	3,073	3,672	3,858	3,822	3,868	**3,924**	3,771
Expenses per 1 car (distribution)	20,484	24,477	25,722	25,478	25,787	**26,163**	25,135
Number of cars	53	81	104	**127**	101	126	592
Total expenses	1,085,665	1,982,639	2,675,061	3,235,754	2,604,517	**3,296,571**	14,880,207

According to ROLF data for 2017–2018, the rating of directions by the number of customers who came to them (calls + online applications) looks as follows: Internet (73%), radio (15%), outdoor advertising (7%), the press (1%), and another (4%).

Currently, almost 80% of the marketing budget is invested in digital. Which tools work best?

Usability of sites. The site is a permanent development zone and a tool to increase conversion (visitors to the Internet applications/calls). ROLF is constantly developing the site in terms of usability, adapting it to any mobile devices.

The site should sell. Package service offers: site, social networks, advertising materials in the file folder with documents. On-line/mobile services/applications: you can send any request online and sign up for the service through your personal cabinet, etc.

SEO-optimization. Target: first page of the search engine output, entering the TOP. Organic traffic is the flow of visitors, which comes to the site from the organic output of search engines. Visitors search for words/word combinations and get the result—pages with organic output of all sites that meet the given requests.

Factors affecting positions in search engines: usability of the site, the quality (conformity of information on the site to the interests of the target audience) and uniqueness of content, the number of links to the site from social networks, the number of links from reliable resources to the company's site. KPI for contractor:

Account for the reporting period (rub.)			90,000
Source of costs	Rate (rub.)	Quantity	Cost (rub.)
Traffic		35,420	90,020
1–30,000	1,750	30,000	52,500
30,001–35,000	7,000	5,000	35,000
>35,001	6,000	420	2,520
Minimum payment			120,000
Calculation of withholding amount			
Forecast traffic (August 2018)		40,500	
Actual traffic (August 2018) was		35,420	
Decrease in actual cost of services by 25% in the reporting period			30,000
Forecast traffic (August 2018)		50,600	
Total payable amount (for the reporting period)			90,000

Landing differs from the usual webpage that it is developed with the only purpose—to convert visitors. In other words, the page on which the visitor will perform the action (lid). KPI for contextual advertising contractor: number of contacts (traffic); contact/contract cost. The purpose of the context is a call/online application [7].

Intermediate results of placement in Audi Tsentr Sever Dealer Center (dynamics of key indicators, general report by sites for the period, the cost of the worksheet does not include online applications):

	March	April	May	June	July	August
Expenses (rub.)	1,209,365	868,925	574,393	1,146,704	999,463	1,178,282

[a]CPC—cost per click
[b]CR—click rate

There is an obvious trend in the percentage of conversion of a click into contacts, contacts into working contacts. Approximately 10% of all requests are transferred to worksheets. A significant increase in the cost of a click since June and, consequently,

a contact is directly related to the placement on the TOP positions in the issue for most model requests.

Traffic efficiency. Statistics on quality appeals in terms of advertising campaign for the period March–August 2018 in Yandex:

Campaign	Cost	Sessions	Worksheets	Cost of worksheet
audi_new_of_diler_msk	1,283,911	9,182	90	14,266
audi_new_q7_msk	447,568	3,875	15	29,838
audi_new_buy_msk	433,646	3,280	5	86,729
audi_new_q5_msk	363,563	2,431	9	40,396

In Google:

Campaign	Cost	Sessions	Worksheets	Cost of worksheet
audi_new_sever_msk	101,434	5,111	81	1,252
audi_new_q3_msk	88,121	4,096	34	2,592
audi_new_of_diler_msk	127,020	2,220	27	4,704
audi_new_inmarket_net	44,414	8,464	16	2,776

Statistics on quality appeals. Brand traffic for the period March-August 2018 in Adwords:

Advertising campaign	Cost	Sessions	Contacts	Worksheets	Cost of worksheet	SR (%)
Total statistics	1,024,120	30,576	886	197	5,199	5.36
Total minus brand	909,481	25,212	454	114	7,978	3.76
Brand	114,639	5,364	432	83	1,381	12.90

In Yandex:

Advertising campaign	Cost	Sessions	Contacts	Worksheets	Cost of worksheet	SR (%)
Total statistics	3,883,108	51,472	1,734	327	11,875	5.16
Total minus brand	3,714,188	40,533	888	189	19,652	3.46
Brand	168,920	10,939	846	138	1,224	11.46

The results of the period:

- The increase in the cost of contact and working sheet is due to the need to be at the first positions in the issue of model requests, the cost of which often exceeds 2,000 rubles. More than 20% of key requests require a rate of over 300 rubles to enter the special location.
- Despite the fact that for all brand requests there is a maximum presence in the organic issue, it is necessary to pay attention to the fact that competitors and aggregator sites also actively place advertising campaigns at the request of dealerships, which can lead to an outflow of loyal audience.

What has been done? Network campaigns have been strengthened (the list of models has been expanded; images in all available formats have been added: standard (aspect ratio 1:1), adaptive, widescreen; coverage has been increased through the rate).

Campaigns on the network are considered to be the main growth point: extended Google ads have been downloaded; mobile versions of ads have been downloaded; Audi Q7 audience Yandex (Audi Q7 contact database) has been launched: on users + look-a-like; Facebook advertising campaign has been launched on Audi Q7 users.

Automated unloading. It is not the general communication that works—"we have better conditions for the best car", but a specific offer for a specific car, spare part, service:

- It is necessary to unload the entire flow (availability, delivery, vehicles with mileage).
- Quality of ads (cars must have "live" photos, users react less effectively to advertising images).
- It is necessary to specify the cost of the car (users do not react to ads without price).

SMM. Does the dealer need social media? If the company does not deal with its own reputation, competitors will deal with it.

The role of social networks in SEO is a steady trend and their importance in ranking factors will only grow. Links from social networks and activity in official communities (likes, reposts, comments, number of subscribers) form a set of social responses. But search engines monitor the "signals" from social networks, and if they are constant, search engines will take them into account as a positive factor in the ranking. An important factor for news output: the more active the users share the news on social networks (with reference to the original source), the better it is for ranking in the news output [8–12].

SMM means fast indexing, if the search engine has not had time to index new material on the site, that is, the probability that the search robot will switch to it from a social network. And faster indexing, in turn, has a positive impact on news output. For the company's website it means faster output of the website in the TOP.

SMM is an additional traffic channel with clear targeting:

- A huge audience that is easy to target (gender, age, place of residence, etc.) and interact with.
- In 90% of cases it is not very easy to get information about a person (car owned, interests, hobbies)—free material for research and analysis.
- A tool for returning lost customers (social networks usually bind an account by phone number).
- So far, the cheapest channel of communication with the client.
- Direct advertising in social networks has not tired out the users yet, does not cause much annoyance, so it works.

Technologies for measuring communication efficiency

Call tracking is a technology to determine the advertising sources from which customers' calls come. There are two types of call tracking: static (linking one phone number to one advertising source, for example, advertising in a magazine) and dynamic (technology for replacing and showing a specific number to each unique visitor to the site). The second option allows you to track an advertising source accurate to a search phrase, and contextual advertising—to a specific ad.

Static call tracking is the linking of one phone number to a single advertising source (e.g. a magazine ad). Dynamic call tracking is a technology of substitution and display of a certain number to each unique site visitor. This type of call tracking allows you to track the advertising source to the exact search phrase, and contextual advertising—to a specific ad.

You can measure 99% of marketing communications on the Internet.

Currently, there are 3 leading players in this field on the market. Here are some examples of how sources are measured:

End-to-end analytics system. First level/holding level:

Source or channel	Cost, rubles (% of total cost)	Worksheet (achieved transitions to the target)	Cost of worksheet, rubles
1. Yandex.Metrica/CPC	1,013,408.04 (77.29%)	**453 (41.75%)**	2,237.10 (185.13%)
2. Google Analytics/CPC	297,688.22 (22.71%)	176 (16.22%)	1,691.41 (139.97%)
Total	1,311,096.26 (100%)	1,085 (100%)	1,208.38 (100%)

Second level/campaign level/Yandex.Metrica

Source or channel	Cost, rubles (% of total cost)	Worksheet (achieved transitions to the target)	Cost of worksheet, rubles
1. 14566327_ROLF_Yasenevo _Toyota_Search_Msk_Obschie	633,703.27 (62.53%)	**262 (57.84%)**	2,418.71 (108.12%)
2. 18727711_ ROLF_Yasenevo _Toyota_Set_Msk_Rav4	66,887.16 (6.60%)	46 (10.15%)	1,454.07 (65.00%)
3. 18727703_ ROLF_Yasenevo _Toyota_Set_Msk_LC200	103,568.84 (10.22%)	41 (9.05%)	2,526.07 (112.92%)
4. 18727708_ ROLF_Yasenevo _Toyota_Set_Msk_Prado	80,228.76 (7.92%)	25 (5.52%)	3,209.15 (143.45%)
Total	1,013,408.04 (77.29%) (1,311,096.26—100%)	453 (41.75%) (1,085—100%)	2,237.10 (185.13%) (1,208.38—100%)

Third level/key query level/Google Analytics

Source or channel	Cost, rubles (% of total cost)	Worksheet (achieved transitions to the target)	Cost of worksheet, rubles
1. Toyota Yasenevo	25,465.45 (4.02%)	**44 (16.79%)**	578.76 (23.93%)
2. Official Toyota in Moscow	189,687.59 (29.93%)	41 (15.65%)	4,626.53 (191.28%)
3. Toyota	90,668.39 (14.31%)	26 (9.92%)	3,487.25 (144.18%)
4. Official Toyota Moscow	19,271.73 (3.04%)	21 (8.02%)	917.70 (37.94%)
Total	633,703.27 (48.33%) (1,311,096.26—100%)	262 (24.15%) (1,085—100%)	2,418.71 (200.16%) (1,208.38—100%)

Large amounts of information entering the database should be processed in such a way that only significant values are allocated. In the above tables you can see how this can be done and presented. Marketing and sales managers have the opportunity in real time to extract from them everything that is necessary: any kind of analytics, statistics, indicators, operating results and make management decisions on them.

Based on the results of the market share assessment, ROLF increased the share of clicks on its landing pages attributable to it from the total number in the segment of the Internet provider (Yandex, from 15 to 18–20%, 2018), and accordingly traffic, wherein this without increasing the cost of promotion.

An effective advertising strategy is built on the basis of call tracking data on user behavior. The CPA model (Cost Per Action) is best suited to achieve these goals.

With this model, only certain user actions are paid for on the advertiser's website, which is impossible without call tracking. The choice of CPA model also influenced the company's advertising strategy. For example, they decided to completely abandon the media placement, determining its inefficiency. The assessment showed that the cost of contact from these sources is 3–4 times higher than the cost of contact coming from the context.

The advertising strategy has been adjusted based on the examples that have been opened in the process of analytics. Some queries, traditionally considered the most conversion ones, in practice are not. A vivid example is the company's brand request, for which there is a struggle in context. It turned out that the cost of a call from such a request is tens of times higher than expected.

Costs were reduced due to experiments on the redistribution of texts and landing pages. When it became clear that the request is effective and works on other brands, the texts were changed for not to spend money on attracting an audience that isn't interested in the advertiser's offers. Landing pages were also changed when there was a chance that the user doesn't find what he is looking for on the site, and that is why he leaves.

Efficiency. Data on the growth of the Russian automobile market and the ROLF company:

Years	2013 (%)	2014 (%)	2015 (%)	2016 (%)	2017 (%)	2018 (%)
Market	−1.9	−9.1	−38.2	−13.3	+11.9	+12.8
«ROLF»	+18.2	+14.4	−31.9	+17.1	+15	+15

These were the years of market instability, against which ROLF showed high results, being the leader of the Russian automobile business. ROLF data for 2019 hasn't been published yet, but the presence of such brands as BMW (+16%), Mercedes-Benz (+8%), Genesis (+19%) in the holding allows us to hope for a positive trend [10]. At the same time, the Russian market recorded a fall of −2.3%.

4 Conclusions

Digital technology is widespread. The possibilities are almost endless. We examined in detail several key sections of digital marketing and sales technologies in the marketing management of a dealership. We saw how the transition from general ideas about the work of the company to specific indicators, tools and solutions takes place. However, technology doesn't work alone. And only a deep understanding of the business and the processes occurring in it, allows the use of digital technology. What allows the company to grow steadily, work efficiently and achieve a leading position?

The simultaneous use of various tools, technologies and software products. Including all possible metric systems that are on the landing pages of the enterprise,

these are Calltouch, CallKeeper, Calltracking, CoMagic, CALLBACK HUNTER, Google Analitics, Yandex Metric.

Diversification. Sustainable growth and development is demonstrated by companies that include a significant number of dealerships of various premium brands and the mass segment. In addition to car sales, these dealerships provide customers with many related services. All this work is fully happening or supported by digital technology. Diversification of the product and services allows maneuvering the company's work in a permanent state of market stagnation and periodic economic crises.

KPI. Key performance indicators used and developed by the company for all business participants allow you to have an adequate online picture of what is happening, the ability to determine the status and make control actions in the current situation in an optimal way.

Big Data. Sales and marketing managers, enterprise managers must keep in control and effectively manage business processes with large databases. It's impossible to implement without our own ERP-system (Enterprise Resource Planning), which must be constantly upgraded by the company's specialists in accordance with the needs of the business.

The effect of synergy. Integrated marketing—each employee of the leading enterprise works with full dedication, many have related specialties and managers at each level participate and help subordinates work. All members of a single team are aimed at the success of a common cause.

The Product Development System Category: Components and Modeling Approaches

Ekaterina P. Garina, Elena V. Romanovskaya, Natalia S. Andryashina, Yaroslav S. Potashnik, and Alexander P. Garin

Abstract The article reveals the categorical apparatus on the topic of research. A set of elements of the product development system is proposed, as well as a structure, approaches and methods of system design, highlighted by systematizing scientific views on the nature and content of corporate systems. Results of the proposed approach to product development system modeling serve as the basis for a proposal of the author's interpretation of the definition of "product development system". Design practices for modeling systems in domestic production allow us to determine components of systems for creating products in the form of a combination of: production products; landscapes of processes of the higher secondary and subsequent levels, participants and KPI of the product development system. It is recommended to consider the following decisions for development of domestic production from the position of primary product development systems: (1) design of product-production systems in terms of flexibility of their practice-application; (2) product and technological integration of systems, taking into account the principles of product lifecycle management (PLM).

1 Introduction

In the works of scientists related to enterprise systems engineering [1–3], under the product development system ("PD system") it is proposed to understand as:

- solutions of the basic processes of a product and its production conceptualization—design processes of production systems with dedicated phases, steps and control points; decomposition of work, a set of processes, methods, and tools; issued by the management regulations, etc.;
- methodologies, methods, models, workflow processes in all areas of product development, based on the PLC product cycle;
- lined up product systems: (1) corporate systems—production system and product development system; (2) a service system for servicing the product creation process; (3) product support system—resource support and tools for supporting operational activities.

In our opinion, the interpretation of the Product development system category should take into account the clustering of decisions on its formation from the perspective of related research areas: engineering design, organization of the production process, operational management and include a set of decisions on the main processes for conceptualization for product and its production (technological, production, business processes)—creation of production systems; decomposition of works, used methods and tools; written management regulations, a designed system for managing product attributes, managing changes to the project, etc.

2 Results of the Study

In the study, we will focus on the component systems for creating products presented in the form of an integration network of enterprise systems, which includes (starting from the top level in descending order) (Fig. 1):

1. Transformation subject—operand (material, design…)—a product of production, which is a multi-component adaptation system/design/result of the implementation of technological processes, the content of which, as well as its formation, is predetermined by scientific and technological transformations in the course of implementation of production relations, and development involves: (a) change in internal properties (change in structure), (b) change in external properties (change in shape), (c) change in configuration (spatial, different); possessing signs of high technology, technological effectiveness and novelty, high cost and adaptability of production [4, 5].
2. The processes of the highest level of the PD-system—the key elements of which are: (a) relations—functional, physical characteristics of the product of production; (b) components—"building blocks", their physical decomposition; (c)

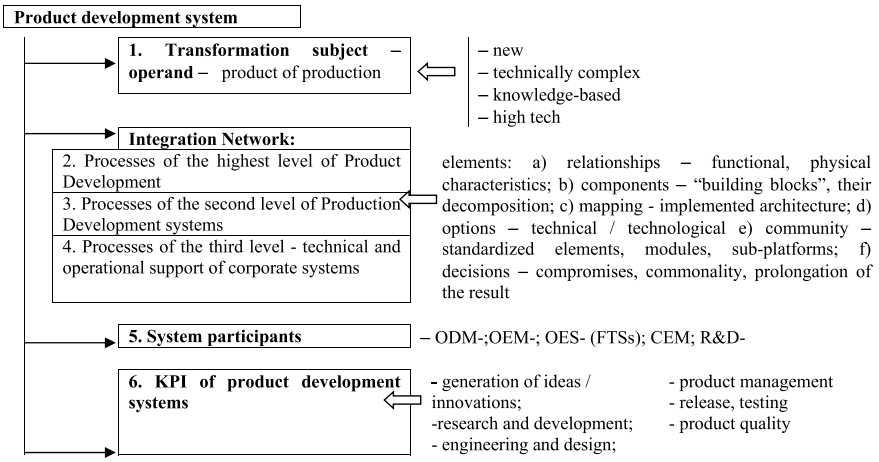

Fig. 1 Product development system model

mapping—implemented architecture (integrated architecture, modular architecture, their composition); (d) options—technical/technological, market options, …; (e) community—standardized elements, modules, subplatforms; (f) decision making—compromises, commonality, and prolongation of the result [6, 7];

3. The production system (specialized production systems (DMS), flexible production systems (FMS), reconfigurable production systems (RMS), etc.)—a set of resources, as well as a set of production, technological and other processes, and production equipment [8, 9];
4. The system of technical and operational support for corporate systems—production and process management; systems integration, IT support, etc. [10];
5. Participants of the system [11]:

ODM participants	Developers of the original product with a unique design or special characteristics
OEMs	Manufacturers of products with a trademark or brand (vendors)
OES manufacturers	Suppliers of product components of the first (FTSs-suppliers) and subsequent levels (sub-suppliers)
CEM manufacturers	Contract manufacturers manufacturing a product with a customer's trademark (OEM)
R&D Suppliers	Research centers, technology suppliers, "production designers"

6. KPI of product development systems (Table 1):

Model of the product development system can be represented in varying degrees of abstraction due to changes in production conditions and new elements. In accordance with the idea put forward, the approach to modeling PD-systems is reflected in Fig. 2:

In accordance with the idea put forward, the characteristics of PD systems are [12]:

Table 1 KPI indicators of the product development system by periods (% of indicators used by industry manufacturers for the period of their total number) [13]

Product development system performance	In the 1990s	In the 2000s	In the 2010s
P@D expenses, % of sales	–	79	79
Intellectual Property Indicators (Patents/Trademarks (filed, granted))	61/21	63/–	61/–
Total staff P@D	–	60	67
% increase or decrease in staff R@D	–	31	
% of sales of new products in the general assortment	–	56	62
The volume of new product releases	51	54	58
% of products/projects in active development	–	49	53
% profit due to the release of new products (product viability index)	–	49	38
% of product at the stages of conceptualization, planning and evaluation	29	36	–
Average project efficiency (return on investment, return on project)	34	32	48
% investment in new product development	56	48	41
product portfolio value (aggregate aggregated indicators)	–	–	35
ROI (return on innovation, calculated using a combination of methods)	–	–	32
Top 5 Intellectual Property Indicators in the 1990s	% of industry manufacturers using these indicators		
patents filed/pending	61		
trademarks filed/issued	21		
IP technology	11		
% of approved patents	10		
IP technology in acquired licenses	9		

1. the degree of complexity—is determined by the degree of manufacturability of production, number and relationship of system components;
2. the degree of standardization—determines the interchangeability of systems or their elements;
3. the degree of novelty—is determined by the level of technological readiness (TRL), the level of readiness for integration (IRL), the level of readiness for production (MRL), the level of readiness of the system (SRL) and operational readiness for production;
4. degree of quality, based on the practical application of the methodology of PROsys, LLC in domestic production, can be determined by the principles: (a) transparency of the process; (b) synchronization of individual workflows; (c)

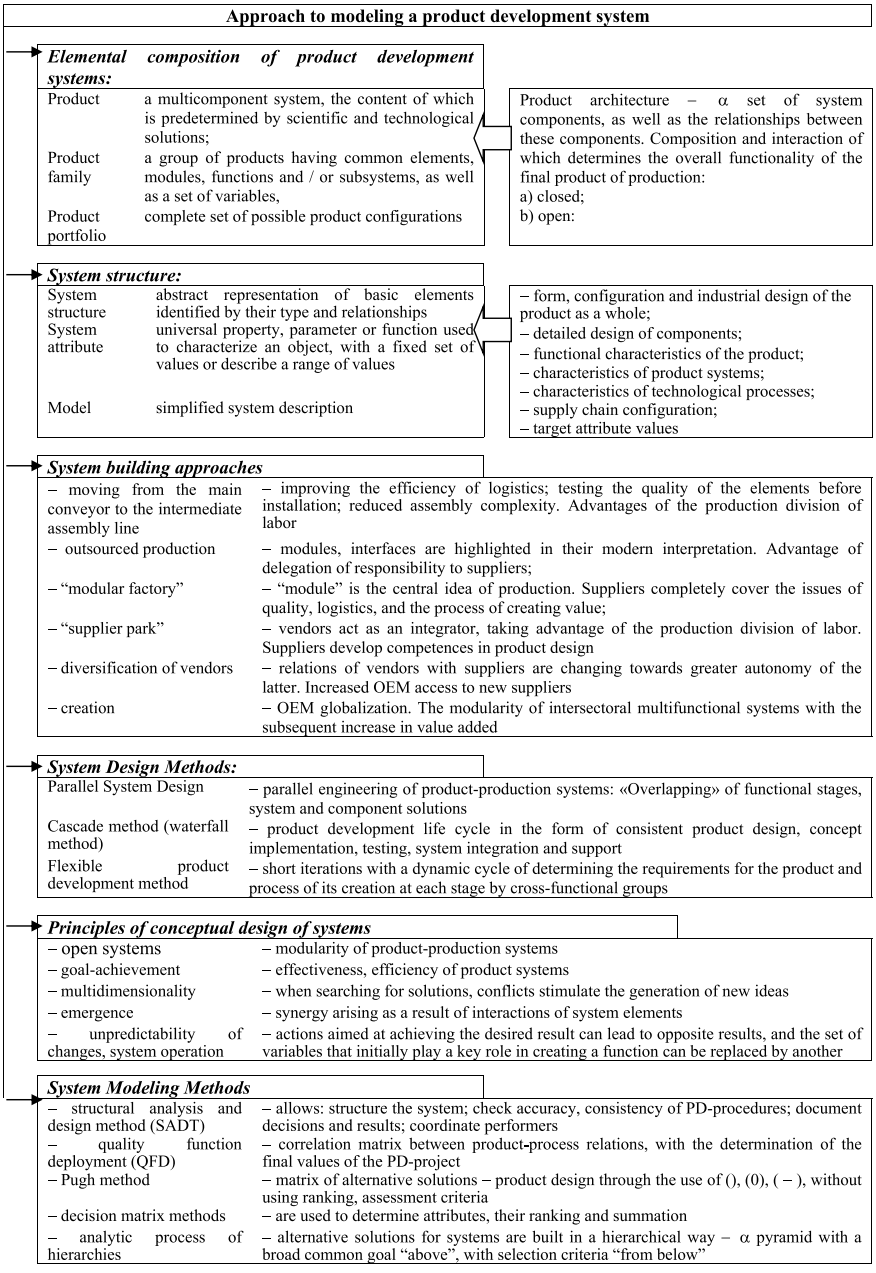

Fig. 2 Approach to modeling a product development system

managing the timing of the launch of production and product on the market; (d) management and control of the budget; (e) engineering outsourcing.

3 Conclusions

This study suggests understanding:

- under the product development system—a set of decisions on the basic processes of conceptualizing the product and its production; under the comprehensive *development of product development systems*—process of multi-dimensional adaptive integration interaction of all participants in the system (systems of business structures) which is based on the early involvement of all its participants in the project, coordination of goals and their interests, distribution of risk and reward, as well as achieving balanced processes (business—processes, technological processes) in the implementation of common goals for the project;
- components of the systems presented in the form of integration network of corporate systems of the enterprise, consider: 1. The subject of transformation is a product of production; 2. Process landscape: higher second and subsequent levels; 3. System Participants—ODM-; OEM-; OES- (FTSs); CEM; R&D-manufacturers; 4. KPI of product development systems;
- about the main decisions on development of domestic production from the position of primary product development systems over the production concept in the future it is recommended to consider: (1) design of product-production systems in terms of flexibility of their practice-application; (2) product and technological integration of systems, taking into account the principles of product life cycle management (PLM); (3) generation of production processes based on the application of knowledge (analog thinking); (4) the configuration of the production process by means of dynamic visualization.

On the Prospects of Digital Transformation of the Field of Sports

Andrey A. Dashkov, Maria N. Belousova, and Vladislav Yu. Pokazanev

Abstract The article deals with the development of professional sports in Russia during the digital transformation of the economy and the unexpected global economic crisis caused by the pandemic and the fall in prices for energy resources. The article studies the situation in the sports industry by the example of Russian football clubs of the highest league. The economic analysis of activity in the context of sources of financing and the use of modern tools to expand the number of clients (fans) of professional football clubs was conducted. The comparative analysis of sources of income of Russian football clubs of the highest professional league was made. There is a rather strong dependence of Russian football clubs on public sources of funding, which, according to the authors, does not contribute to the use of modern information and communication technologies and market mechanisms for managing the sports industry to achieve market efficiency. A definition of a "continuum of funding" is given, revealing possible approaches to the financing of physical activity and sport in different countries, as well as ways in which funding could change. The prospects of using some modern information and communication technologies for football development are considered. The use of social media to promote sporting events was analyzed. The shortcomings of the Russian sports industry are noted and recommendations on the development and implementation of modern information and communication technologies are given. The article forecasts the impact of the corona economic crisis on the development of the Russian sports industry, and concludes that it is vital and urgent to turn the sports industry into a business industry.

Keywords Sport · Football · Sources of funding · Continuum of funding · Attendance · Digital transformation · Social media · Corona economic crisis

1 Introduction

Activities in the field of leisure, culture and sports in Russia are treated in two ways. On the one hand, words emphasize their importance, and on the other hand, according to Rosstat in 2017, this activity was about 0.8-0.9% of GDP [1]. The total contribution to GDP growth from these activities is negative and amounts to −0.42 p.p. (percentage point) [2]. There is no open information about the share of each of the components of these directions. It should be noted that in some developed countries the share can be much higher. "The Strategy for the Development of Physical Culture and Sports in the Russian Federation for the Period until 2020", adopted in 2009, was mainly aimed at "sports of the highest achievements" on the eve of the XXII Olympic Winter Games in Sochi in 2014 and the World Football Championship in Moscow in 2018 [3]. The economic situation at that time allowed to look into the future quite optimistically and to develop mass physical culture and sport as a necessary element for improving the health of the population, using the fact of holding the largest sporting events.

2 Background and Methodology

The article analyzes the economic situation after the largest sporting events, as a result of the implementation of "The Strategy for the Development of Physical Culture and Sports". The information base of the research was open Russian and foreign sources of information, such as the project Sports.ru, which considers itself the leader of the sports publishing company Tribuna Digital, which unites more than 7 million fans [4], a website about sports and leisure [5], an electronic periodical "Sport-Express Internet" [6], "Sport Daily"—the leading sports website of St. Petersburg [7] (https://www.sportsdaily.ru/), the site "Football @ Soccer" [8], online portal of statistics [9] and many other publications related to the sports industry.

The methodological basis of the article was the analysis of sources of financing, attendance at football matches, use of social networks, etc., comparison of approaches to solving problems of organization of financing and management of sports in different countries, and generalization of the research results into Russian reality.

It should be noted that the following situation with the financing of physical activity and sport in the world is presented in Fig. 1 as a continuum of financing. Three models are distinguished: American, Asian and European models [10]. They all differ in the degree of government involvement in the financing of physical education and sport. The extreme position is taken by the Asian countries headed by China, where virtually everything is controlled by the communist party and it actually reproduces the "Soviet" system of physical education and sport management. An essential

Fig. 1 Continuum of funding physical education and sports

feature of the Chinese approach is certainly the reduction of income taxes for those corporations that finance culture and sport from 25 to 15%, and in some cases up to 3% [11]. The other extreme position is occupied by the USA, where sport has no budget money, mass sports are held by universities, schools, local authorities and various kinds of patrons, and "sport of higher achievements" is built as a real business. The foundations of professional athletes are laid down in schools and continue in universities, which have "cosmic" budgets that allow not only to provide all kinds of benefits, scholarships and grants to their athletes, but also to foreign, including Russian ones. The National Collegiate Athletic Association (NCAA) is a not-for-profit organization with more than 1 billion dollars in revenue in 2018, 79% of which came from the sale of advertising and television rights (NCAA—Statistics & Facts). The intermediate position on the continuum is occupied by Europe, where the mixed models of financing of physical culture and sport are well combined and have their own peculiarities in each country [12]. In fact, Russia has preserved the Soviet system of financing and management of physical culture and sport, adding to this system oligarchs who use sport to meet their own ambitions.

3 Discussion and Results

On the example of sport, taking football as the most mass sport, let's consider what is happening in this industry. Today, most sports federations and sports clubs in Russia are funded by the state. This means that the main stakeholder is the state, and the task of attracting, for example, fans is seen in this case as a secondary task, especially with significant efforts to create an attractive spectacle.

In football, the following situation is observed, as shown in Table 1 (Russian Premier League (RPL) clubs budgets 2019/20, 2019), which shows the sources of funding for Russian football clubs.

As we can see, RPL clubs have quite a few budgets, most of which fall on regional budgets or the budgets of state or near state companies. The average budget of a football club is more than 3.64 billion rubles or more than 50 million euros. The budget of the richest Russian club "Zenit" exceeds 173 million euros, which is quite

Table 1 Sources of funding for football clubs

	Football club	Budget	Sponsor
1	“Zenit”	12.5 billion rubles	“Gazprom” and its subsidiaries—bank and oil producers (at least 50% owned by the state)
2	“Spartak”	11 billion rubles	“Lukoil” (nominal holder of 61.8% of shares—Bank of New York), IFD Kapital (private investment company), Bank “Otkritie”
3	“Lokomotiv”	5.75 billion rubles	“OAO RZhD” (state company)
4	“Krasnodar”	5.5 billion. rubles	Sergey Galitsky and the title sponsors of FC Krasnodar
5	“CSKA”	4.3 billion rubles	“Rosseti”, “Aeroflot”, Ltd. “Hyundai Motor SNG», EKA (fuel company) and others
6	“Dinamo”	4 billion rubles	VTB Bank (acquired a controlling interest for 1 ruble)
7	“Rostov”	2.4 billion rubles	Rostov region, “TNS energo Rosttov-on-Don”, TMK, NZNP
8	“Arsenal”(Tula)	2.1 billion rubles	“Rostec”, “Rosneft”, NPO “Splav” (Tehmash), KBP, Alisher Usmanov
9	“Akhmat”	2 billion rubles	“Akhmat Kadyrov Foundation” (public organization), Moscow Industrial Bank, holding company “SAT & Co” (Kazakhstan)
10	“Rubin”	2 billion rubles	“TAIF” (private group of companies), “Ak Bars” Bank, “Kazanorgsintez”
11	“Krylia Sovetov”	1.6 billion rubles (86.48% from the regional budget)	Samara region, “Pari Match”
12	“Sochi”	1.1-1.5 billion rubles	Boris Rotenberg
13	“Ufa”	1 billion rubles	Republic of Bashkortostan
14	“Orenburg”	1 billion rubles	LLC “Gazprom Dobycha Orenburg”
15	“Ural”	1 billion rubles	Sverdlovsk region, “Sinara Group”, SKB-Bank and TMK (private companies)
16	“Tambov”	Plan 600–650 million rubles (350 million rubles from the regional budget)	Tambov region, “Pari Match”

Table 2 Average attendance of football matches by materials [16]

Country	Season 18/19	Season 17/18	Season 16/17	Season 15/16	Season 14/15
Germany	43,467	44,657	41,526	43,357	43,583
England	38,188	38,273	36,805	36,461	36,175
Spain	27,112	27,290	28,181	27,977	26,794
Italy	24,983	24,784	22,007	22,213	22,167
Russia	16,820	13,956	11,414	11,043	10,416

comparable, if not with the world football giants, with the famous European average clubs. Of course, football is not a production of steel or oil, and investments will not always bring profit to the owners, but it would be desirable that football is not a burden on the Russian budget, and considerable salaries of players correspond to high attendance at football matches [13].

Of course, Russia, like other countries, has its own specific features and traditions, but in many countries, particularly in Germany and England, football brings profit to its owners, and some of the famous owners, like those of the English clubs, are affiliated with Russia [14]. The total income of the clubs in the First Bundesliga exceeded 4 billion euros in the season 2016/2017, even the income in the Second Bundesliga was 635.2 million euros, and the total contribution of football in the form of taxes to the national budget exceeded 1 billion euros [15].

Why did German football generate such income? Let's consider only one indicator, namely attendance at football matches, which is shown in Table 2. As we can see, the average attendance of football matches is kept at a consistently high level, especially in England and Germany, exceeding domestic attendance of football matches almost three times.

It should be noted that the population of Russia is almost twice that of Germany and more than twice that of Great Britain, Italy and Spain. It is encouraging that attendance of football matches is growing, but it is again a credit not to football clubs, but to the Russian government, which has done a lot for the World Cup to be held in our country. But on the whole, the situation in football reflects the fact that sport in our country is a cost, not a real business that brings income not only to players, but also to the state budget. Therefore, speaking of the digital transformation of sports, we must first of all separate physical education and sports for health, from professional sports. The first one, of course, will be financed by our taxes, but professional sport must earn. Only by turning professional sport into business we can really talk about the digital transformation of this activity. According to the "Parlamentskaya Gazeta" in 2018, "88% of the income of Russian clubs comes from sponsors. Only 9% of the revenue is from TV rights, and another 3% is during game days" [17].

How do foreign clubs manage to earn profit for their owners and bring joy to the audience? It is clear that a spectator at the stadiums, providing the match revenue, is not the only source of income for football clubs. The clubs get income:

- from the sale of TV rights to the matches, it is usually more than 50% of income in the leading English, German, Italian;
- from marketing agreements with sponsors, which include the world's most famous brands such as Adidas, Nike, General Motors, Etihad Airways, Qatar Airways, Emirates, Siemens, Standard Chartered, Fiat Chrysler Automobiles, Kia, Gazprom, which is the sponsor not only of the Russian "Zenit", but also of the German club "Schalke 04" and many others. Sponsorship contracts reach 60 million euros per year [18];
- from the sale and rental of players: therefore, in the summer transfer window in 2019, European clubs of the most famous leagues have spent on players 5.5 billion euros, which means that others have earned this money [19];
- from renting out stadiums for various cultural and entertainment events, the most successful clubs also earn income for participating in European Cups.

Undoubtedly, income is possible only under one condition, namely, there is a product, which in this case is a spectacle—an impressive aggressive football, and a loyal consumer of this product. This spectacle is created primarily by football players, so when you answer the question: "What distinguishes Russian football from football in advanced football countries?", you can answer briefly, namely the lack of professional players of high class. According to experts, if there was no limit on foreign players, some Russian clubs would consist entirely of foreigners. It is clear that training a professional requires both money and time. But it is true professionals who create a spectacle that attracts billions of spectators around the world.

Let's see how professionals are trained in Germany. In due time, after significant victories at the world championships in Germany, there was a predictable decline. The failure of the 1998 World Cup and the European Championship in 2000 and the subsequent dissatisfaction of the football sponsors prompted the German Football Association (DFB) to implement reforms related primarily to the training of football youth, ready to worthily replace German football legends such as F. Beckenbauer, L. Matthäus, J. Klinsmann, H. Müller and M. Sammer. These reforms concerned the following aspects [20]:

(1) 27 thousand DFB amateur clubs received support related to attracting children to football lessons.
(2) A support network for young football players, boys and girls alike, was established to ensure that not a single talent is left unnoticed.
(3) All professional clubs became obliged to have their own youth training center, otherwise they would not have received a license to play in the first and second football leagues.
(4) In order to ensure the safety of young people training in football centers, links and cooperation with schools were strengthened to obtain a "civilian" non-football profession.
(5) In order to improve children's and youth competitions, a football league was created for players under 19 years old.
(6) Germany's junior national teams are being created, training on the same principles for all national teams.

(7) The system of training children's and youth coaches is also being reformed as part of a unified training and game philosophy.

The results of such a reform were not long awaited, as in 2014 Germany became a four-time World Cup winner.

Of course, Russia is also undergoing changes and attempts are being made to refresh the situation. The Russian Football Union (RFU) is carrying out reforms by testing a new system for training football players in traditional children's and youth schools. There is some success, for example, the Russian junior national team won the 2013 European Championship and some of its players have become prominent players in well-known European football clubs (Alexander Golovin in "Monaco", Rifat Zhemaletdinov in "Lokomotiv", Anton Mitryushkin in Swiss "Sion"). But the scale of such work is significantly different from the German one, according to one of the coaches of the youth national team of Russia Nikolay Kocheshkov, "there is one Russian player for 14 German players" [21], and no one cancelled the dialectical law of "transition of quantity to quality"… Of course, another important aspect is the psychology of Russian players, so according to the same coach, "having earned a million, our players think about how to spend it. Foreigners—how to earn another five". Hence the well-known cases when the inability to cope with the accumulated fame and money leads our leading players even to serve real sentences [22].

Let's also consider the aspect related to the creation of a loyal consumer with the help of modern information and communication technologies. In professional sports, along with fans, clients are also representatives of various media channels, advertising and marketing agencies and other marketing intermediaries involved in creating a sports show and distributing it to as many different audiences as possible. Today we are provided with multi-channel opportunities to contact customers through VK, Twitter, Youtube, Facebook, Odnoklassniki, Instagram, Telegram. Wide use of TikTok is next in line. It is obvious that working with these channels requires both financial resources and digital competence. As a result, we observe the so-called "digital gap" between those who have it and those who do not have such capabilities. Table 3 shows the number of subscribers to the social networks of the most famous football clubs.

Table 3 Number of subscribers in social networks

Sports club	Subscribers on Instagram	Subscribers on Facebook	Subscribers on Vkontakte
"Barcelona"	80.9 million	101,112,708	2,118,402
"Chelsea"	19.9 million	47,472,836	121,502
"Zenit"	0.652 million	975,124	1,096,730
"Spartak"	0.458 million	722,193	1,136,702
"Chelsea Ladies Football Club"		2,784,959	

From the information provided, it is clear to what extent modern information and communication technologies are used in Russia. Our most popular football clubs lose even to women's FC Chelsea by the number of subscribers on Facebook, even the number of subscribers in the more popular in Russia network Vkontakte does not make any difference (although Russia beat FC Chelsea Russia there). World clubs have long understood that they are not only sports clubs, but also media companies with a full cycle of news production, marketing companies for brand building, manufacturers and sellers of sportswear, exercise machines and any other sports or about sports attributes capable of bringing satisfaction to consumers and profit to their owners.

Today, sport is very susceptible to technology, the current trend of splicing real and virtual sips creates new opportunities. You can drive on Formula 2 from home or play tennis against Federer or Nadal. The use of technology allows for more spectacular and objective refereeing in game sports. Wireless communication systems for referees, goal-line technology, Video Assistant Referee systems, Electronic Performance & Tracking Systems (EPCS) and electronic systems for monitoring athletes' performance and building up the training process according to individual characteristics have become widespread. The spread of "smart balls", which have a special chip embedded to track the trajectory with a simple smartphone, and balls equipped with video cameras, as well as the emergence of football fields that convert the kinetic energy of football players into electrical energy, which can be accumulated and used, for example, to sanctify evening football matches, is on its way.

4 Conclusions

If Russia wants to turn professional sport into a source of income, it is necessary, first of all, to remove the funding of clubs and sports federations from the "budget needle", depriving them of the possibility to obtain state funding, while the possible initial loss of prestige at world competitions will be paid off by increasing tax revenues. Business will not invest in the budgets of clubs in vain, especially since show business, which certainly includes football, is one of the most attractive and fastest (bringing quick profits) business activities. Today, out of the two goals set for the sports federations: (1) achievement of the maximum result at the largest international competitions, (2) development of mass sports for strengthening of health of the nation, the first one is chosen—it is easier to achieve, and in fact, no work is necessary. And if this task is completed, the use of modern digital technologies and digital transformation will become a vital need to create relationships with consumers willing to pay for unique spectacles.

Undoubtedly, the situation in the sports industry will be significantly complicated by the corona economic crisis caused by the pandemic and the sharp fall in energy prices. It has already been announced that the Olympics will be postponed to a year, there will be no competition at Roland Garros this year, Wimbledon has been canceled, the start of competitions in Formula 1 has been postponed, a huge number

of tournaments and competitions have been stopped, and this is a huge financial and social loss. Sponsorship contracts are being terminated, demand for sportswear, footwear and equipment manufacturers' products is falling, jobs are being cut, etc. The impact of the pandemic on sports is compared with the Second World War. So what should we do in such a situation? Carry out digital transformation, allowing to find new business models and, if not eliminate the impact of the crisis, at least to find new tools for interaction with consumers and new models of monetization of sports, develop a self-paying management system that meets the economic system that will develop after the crisis. For Russia, this is a new challenge related to the management crisis, without solving which Russia will continue to lose its sporting leadership on the world stage.

Digital Monitoring for the Effectiveness of Financing Industrial Clusters in the Russian Federation

Aleksandr V. Voyko, Daria V. Voyko, and Olga D. Gaisha

Abstract The experience of developed countries (such as the USA, France, Germany, and the Netherlands) has proved the effectiveness of cooperation in a certain territory of scientific and educational organizations and production enterprises in order to achieve the synergistic effect of such integration as a cluster. Innovational and industrial clusters have become an effective tool for integrating national producers into the global market for high-tech products, which generally affects both the level of development of the cluster member organizations and the base region and the whole country. The Russian Federation, adopting the experience of developed countries, when conducting a cluster policy, determined the mechanisms of state support for projects of industrial clusters, and therefore the issues of assessing the effectiveness of financing industry of industrial clusters are relevant. The article is devoted to solving an urgent problem—the development of a digital monitoring system for the effectiveness of financing industrial clusters of the Russian Federation. As part of the study, the goal was set to develop a system of digital remote monitoring of industrial clusters of the Russian Federation, which would meet the basic needs for financial control, as well as the specifics of the development of domestic cluster policy. The proposed system of digital remote monitoring of the effectiveness of the development of industrial clusters in the Russian Federation can be used in the current and subsequent monitoring of the financing of cluster programs, to prepare decisions on the allocation of budgetary funds by state and municipal authorities and will allow potential investors to determine the most promising investment tools. The study used methods of bibliographic and logical analysis, synthesis and a systematic approach, mathematical methods of processing statistical data.

1 Introduction

Competitiveness at the international level is an integrating concept, accumulating a set of key issues related to the ability of individual producers to produce competitive goods, as well as the steady growth of national welfare and living standards. When implementing the cluster concept, the emphasis is on improving the competitiveness of the market and maintaining rivalry as the driving force behind the competitiveness of companies. Innovative and industrial clusters have become an effective tool for integrating national producers into the global market for high-tech products.

In accordance with the guidelines for the implementation of cluster policy in the constituent entities of the Russian Federation, approved by the Ministry of Economic Development of the Russian Federation, the main risks for the implementation of cluster policy are:

– erroneous selection of priorities for financial support for cluster policy activities;
– low level of coordination of activities at the federal, regional and local levels in the implementation of cluster projects;
– low level of participation of executive authorities of the constituent entities of the Russian Federation and local self-government in the implementation of cluster projects;
– inefficiency of the cluster monitoring system due to the lack of a single system of indicators for the effectiveness' assessment.

Thus, an important step in the implementation of cluster projects for now is to reduce the risk of implementation and support of inefficient cluster formations by developing a system for evaluating the effectiveness. The solution to the problem of evaluating the effectiveness of financing at the expense of the state budget of cluster projects is considered important, and the use of digital tools in the process of implementing cluster projects strengthens relations within the cluster and provides a greater economic effect.

2 Methodology

An important task in the process of financial support of cluster projects is the analysis of the effectiveness of the subsidy provided, assessment of cluster effects. Cluster competitiveness and effectiveness are addressed by many scientific researchers [4, 7–9, 11, 13–15, 17], as well as issues of evaluating potentially effective clusters and its

participants [2, 3, 6, 12]. In the framework of previous studies, a three-level system for assessing the effectiveness of financing industrial clusters was developed, including indicators of the cluster's influence on the economy of the region, indicators of the cluster's development and indicators of the financial condition of the cluster member enterprises [16]. The previously proposed system of indicators for assessing the effectiveness of financing industrial clusters can provide information necessary for making decisions on the development of cluster policy and is considered necessary for making decisions on financial and other measures of support by state and municipal authorities, and gives potential investors the opportunity to evaluate a potentially effective object for investing. A unified system for assessing the effectiveness of industrial clusters will also provide an opportunity of industrial clusters' ranking by degree of effectiveness and to identify and further replicate best practices.

At the federal level, in 2015 the Ministry of Industry and Trade of Russia developed measures of state support for industrial clusters and criteria for providing this kind of support. Financial state support can be no more than 50% of the total cost estimate, and 30% is generated from the own sources of enterprises participating in the industrial cluster. In accordance with the data provided by the Association of Clusters and Technology Parks of Russia, from 2016 to 2018, state support in the form of subsidies amounted to about 6 billion rubles.

The Ministry of Industry and Trade of the Russian Federation may stop providing subsidies in the following cases:

- the schedule has not been fulfilled by 30% or more (total since the start of the joint project);
- the planned target indicators of the effectiveness of the implementation of the cluster project have not been achieved by 15% or more (for the entire period of its implementation);
- inaccurate information about a joint project is presented;
- the procedure, goals and conditions for the provision of subsidies are violated, which is revealed by the results of inspections of the Ministry of Industry and Trade of the Russian Federation and the authorized state financial control body.

The rules for the provision of federal subsidies covering the share of the costs of organizations participating in the clusters set target indicators for the effectiveness of the implementation of measures. As noted earlier in the framework of the research, the approved system of indicators is not enough to determine the effect of the introduction of cluster programs, since factors such as the impact on the regional economy, the level of personnel development, and the structure of borrowed funds in the cluster are not taken into account [16].

In the process of testing the proposed system of indicators for assessing the effectiveness of financing industrial clusters in the Russian Federation, using the example of a cluster of manufacturers of oil and gas and chemical equipment in the Voronezh region for 2017–2018. The following key points were identified:

- the share of net revenues of enterprises participating in the cluster in the net revenues of enterprises in the region increased from 2.01% in 2017 to 2.41% in 2018;
- the share of high-productive places at the enterprises participating in the cluster fell (from 79.3% in 2017 to 54.7% in 2018);
- failure to achieve the target indicators in 2018 for all 6 key indicators was revealed; in 2017, only 1 indicator out of 4 was achieved, for which it is possible to make a comparison in view of the limited information about the cluster;
- the dynamics of some indicators could not be identified due to the lack of information on the cluster, which indicates the limitations of the current monitoring of the effectiveness of industrial clusters' financing.

It is considered advisable to expand the amount of information collected in order to use monitoring as a tool to improve cluster policy in the direction of selecting the most dynamically developing clusters and to provide timely information on the use of directed budgetary funds according to the methodology developed earlier in the framework of studies evaluating the effectiveness of industrial clusters' financing in Russia [16].

The concepts of "assessment" and "monitoring" are unified in their goals and different in essence: while monitoring acts as a systematic collection of information about the implementation and development of cluster programs, assessment is the next step, the essence of which is to analyze the materials obtained in monitoring progress through calculations, comparisons [5]. Thus, monitoring is the basic material for the assessment and is in no way identical to it [10].

The collection and processing of information about clusters allows us to assess the dynamics of development, achievement of planned indicators and the effects of cluster interaction and the effectiveness of the funds used both from the state budget and extrabudgetary sources, as well as the selection of promising areas and the replication of the most successful practices.

In the process of development and implementation of joint cluster projects, as well as information interaction of participants and promotion of clusters is carried out using digital tools, but the degree of development of issues of their effective use is debatable and should be considered in detail, analyzed [1].

Given the dynamic development of cluster policy in the Russian Federation, it is considered necessary at the regional level and at the cluster level, in particular, to organize a process of continuous data collection and updating information on completed studies in the field of cluster functioning and in the field of innovation, scientific equipment, modern technologies and other results of current activities, which will allow to scan clusters in a continuous mode through the use of modern digital technologies that accelerate the data collection and processing.

3 Results

Currently, a number of platforms that accumulate information on clusters operate in the open access:

- Geoinformation system: industrial parks, technology parks, clusters, developed and supported by the Ministry of Industry and Trade of the Russian Federation: technology parks, industrial parks and clusters are geographically indicated on the map, general information about clusters is provided—specialization, structure, governing body, participants, partners clusters, cluster documents—an agreement on the creation of a cluster and development program.
- A map of Russia's clusters, developed and supported by the Russian Cluster Observatory (under the Higher School of Economics), which is largely similar to the Geoinformation System of the Ministry of Industry and Trade of Russia, but its key difference is the limited nature of aggregated information—clusters of Russia, which are presented in terms of their specialization—innovative and industrial, as well as the level of cluster development—initial, medium, high.

A single set of information on the implementation of clusters and their joint projects is not collected by the existing open access databases, and therefore there is no general aggregated information on the results (and intermediate results) of the implementation of joint projects of industrial clusters. A single system for collecting and processing information that provides data in an open space will increase the informational coverage of the topic of cluster development and will be able to attract both potential participants and investors.

A unified monitoring system in the process of collecting analytical material to assess the effectiveness of industrial clusters' financing should help to improve the conditions and procedures of cluster policy, which will allow further adjustments to the list of subsidized clusters and the amount of support provided.

Based on the platform of the State Industrial Information System, created with the support of the Ministry of Industry and Trade of the Russian Federation, in terms of cluster development in the industry, it is proposed to introduce a digital remote monitoring system for the development efficiency of industrial clusters in Russia.

The main details of the proposed system of digital remote monitoring of the development efficiency of industrial clusters in Russia are presented in Table 1.

Currently, the development of digital technologies allows the collection and processing of information with its subsequent ranking in order to visualize materials on the process of implementing cluster projects.

The Ministry of Industry and Trade of the Russian Federation, as the main manager of state budget funds and as the main regulatory body for the efficiency and targeted use of budget funds, should take measures to ensure monitoring and the processing of analytical data for the year.

The developed system of digital remote monitoring of the development efficiency of industrial clusters should comprise the following blocks, shown in Fig. 1.

Table 1 The system of digital remote monitoring for the development efficiency of industrial clusters in Russia

Subject	Ministry of industry and trade of the Russian Federation
Object	Industrial clusters of Russia
Periodicity	Once a month/quarter (depending on the fact of the presence of changes in the observed monitoring parameters)
Basic functions	• Integrative (a comprehensive description of the processes occurring in the cluster) • Diagnostic (tracking processes and ongoing changes within the cluster, allowing to evaluate these events) • Information (regular receipt of comparable information on the status, development and implementation of joint projects of industrial clusters) • Control (the use of monitoring information in order to monitor the effectiveness of the functioning of clusters, the efficient use of budget funds)

Source Compiled by the authors

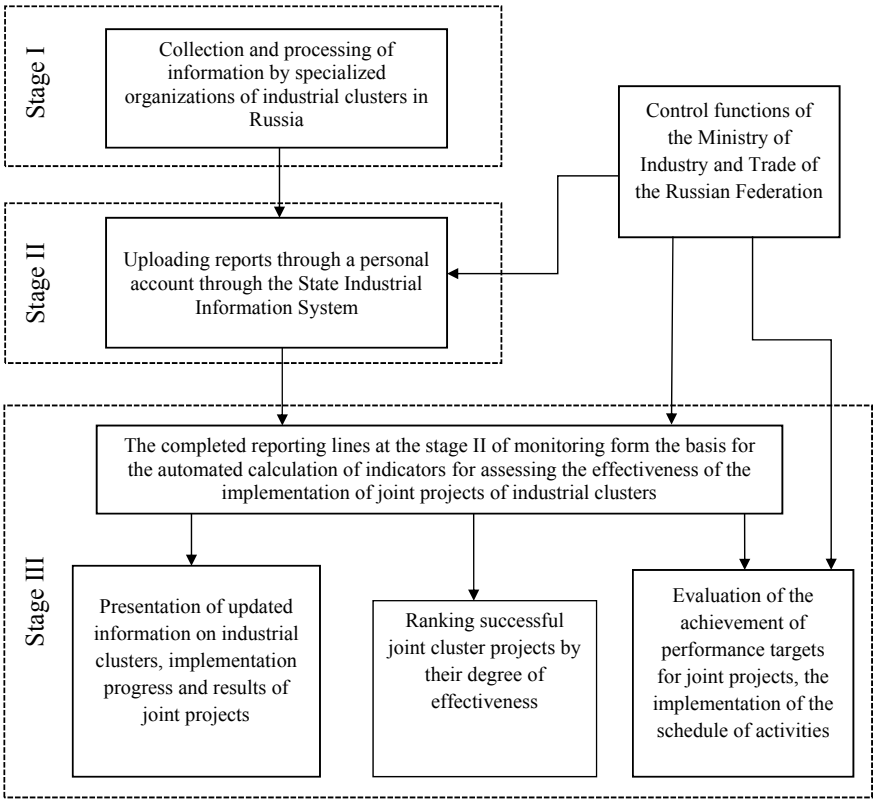

Fig. 1 The system of digital remote monitoring for the development efficiency of industrial clusters in the Russian Federation. *Source* Compiled by the authors

4 Conclusion

Russian and foreign experience in implementing cluster policy reflects the synergistic effect of this form of integration as a cluster. Assessing the effects of implementation and the effectiveness of cluster financing will improve the ongoing cluster policy in order to achieve great synergistic effects of such interactions.

The Russian Federation is becoming more and more involved in the international process of clustering the economy. This process is quite young and not without a number of problems, the identification and solution of which will allow us to fully realize their goals and objectives and will also contribute to the efficient functioning of industrial clusters in the Russian Federation.

Optimisation of Material Flows in the Concept Urban Mining Based on the Use of Long-Term Storage Depot

Svetlana B. Globa, Mikhail Ashkerov, Viktoria Arnold, and Viktoria V. Berezovaya

Abstract ***Purpose***: The purpose of the chapter is to improve material flows in urban areas with the help of long-term storage depots for mineral construction waste remaining after the demolition of buildings and structures for their further use as recycling materials. ***Design/methodology/approach***: Urbanized territories are depots of material resources that are most efficiently used within the framework of circular economy and replace with them fully or partially natural resources. This concept is called urban mining. The authors identify a way to optimize the flow of mineral resources using long-term storage depots and calculate its efficiency using a specific example. ***Findings***: It is shown that the studied method significantly optimizes the flow of mineral resources during the transition to circular economy and the introduction of the concept of urban mining. At the same time, with the given parameters, the current and maximum volumes of long-term storage depots are calculated, as well as the time when the system reaches a reduction in the generated waste in comparison with the volume of their recycling. ***Outlook—further research assignments***: The project is at the initial stage of development and implies the use of optimization algorithms and machine learning for multivariate analysis and decision-making in real time with its further implementation.

1 Introduction

The world is experiencing a trend of global urbanization of the population, that is, the concentration of people in urban agglomerations. According to the requirements set by the UN countries and described in Agenda 2030 [1] as 17 sustainable development goals (SDG), it is necessary to increase the efficiency of natural resources use, reduce waste production and introduce it into the cycle as part of a circular economy, reduce greenhouse gas emissions and organize a comfortable living environment in cities. To achieve these goals optimally fit is the concept of Urban Mining.

Urban mining—resources extraction concept in urban areas for its reuse or recycling combined with up to date database of anthropogenic stock, logistic system according to life cycle of products, urban design of products and efficient extraction technologies [10].

The urban mining concept will lead to the saving of natural resources, reducing emissions, saving places on landfills, saving energy for transportation, reducing waste and using natural territories [5, 18].

Since the urban mining concept is quite new, its implementation will yield some dividends only after a few decades. However, steps towards urban mining should be made already today.

2 Initial Parameters and Method of Optimization of Material Flows in Urban Areas

It was decided to consider the flows of mineral resources in urban areas occurring during the demolition of old buildings and structures and the construction of new structures during the recycling of construction waste. Such mineral resources include scrap of concrete, bricks, it‘s mixture, soil and stones (dredged material), bitumen-containing wastes generated during road demolition, ceramic, gypsum-containing wastes, etc. [7, 11, 13, 17].

The feasibility of introducing recycling is primarily determined by economic efficiency. Economic efficiency is defined as the ratio of the products produced to the costs required to obtain the product, that is achieving great results at the lowest cost. In this case, the term “economic efficiency” can be defined as the most cost-effective and efficient use of recycled construction waste at the lowest cost of their processing.

Factors that affect the efficiency of secondary construction resources use include:

- volumes of generated waste;
- environmental impact of various wastes;

- available methods of waste recycling;
- transport accessibility from the place of waste generation to the place of processing;
- possibility of effective use in production;
- available market for recycled products;
- existence and volume of demand for the received products;
- quality of the received secondary construction materials;
- costs for the production process of waste recycling;
- the cost of producing similar new materials.

The economic efficiency of the use of secondary building materials should be considered not only in terms of production, but also in terms of environmental, social, scientific and technical aspects, as well as the definition of strategic efficiency. The economic effect of recycling is determined by the decrease in the use of primary materials in the construction process, the rapid replacement of secondary resources without reducing their characteristics and increasing the cost of such materials.

The economic effect of the use of secondary materials is primarily due to the reduction of costs for the production of final construction structures or the formation of the final construction product made of secondary construction materials by replacing primary construction materials.

At the initial stage of processing and use of secondary construction wastes, the main economic criteria for determining the way in which they are conditioned may be the following approaches:

- possibility of application of secondary construction resources as a finished product, an element, material at new construction without additional processing;
- use of secondary construction resources as raw materials and semi-finished products for various enterprises of processing industries;
- full utilization of secondary construction resources and storage on bases grounds of waste from their processing due to the lack of economic feasibility of their further use.

In the complex processing of secondary construction resources, two main options are used: sorting and processing of secondary construction resources directly at the construction site, i.e. at the site of their formation during construction and dismantling works using mobile crushing and sorting plants or sorting and processing of secondary construction resources at bases-polygons located on specially designated separate sites using stationary processing complexes. Both methods have their own advantages and disadvantages.

In the case of construction waste treatment at the construction site, it is not possible to use high-performance equipment to ensure high quality of the final processing product.

If waste is processed at specialized landfill bases, additional costs are incurred for transportation of waste to the processing site. In this case, it is possible to process waste at stationary complexes of high capacity, for deeper and better processing. It

is also possible to plan the production and economic activity of the enterprise for a long period of time.

Optimization can be carried out based on various indicators. To demonstrate the concept, it was chosen the ratio of the volume of recycled materials to the total volume of principle possible recycled materials η. The parameters $V_{recycled}$ and $V_{recyclable}$ are functions of time and have a strong correlation with seasons, depending for example on the amount of construction and demolition at the moment or a load of the recycling industry. Efficiency will strive to 1 with a depot of unlimited size and not having a time limit. With this depot, no local temporary changes in material volumes will matter.

$$\eta = \frac{V_{recycled}}{V_{recyclable}}$$

$$if\ t_{stockpit} \to \infty \quad \lim_{V_{stockpit} \to \infty} () = 1 \tag{1}$$

In turn, in a system without a depot, the second usage will occur if and only if the "resource available" event $P_{resource}$ and "resource needed" P_{build} coincides. And the volumes of extracted and used resources in these events must be equal at each moment in time.

$$P_{recycling} = P_{build} \text{and} P_{resource}$$

$$V_{build} = V_{resource}$$

A building construction time is usually one year. In turn, the demolition of a building usually takes no more than 1–2 months. And also, usually the volume of extracted and necessary resources does not coincide. It makes obvious that $P_{recycling}$ can be equal 1 but in reality, will be less due to the reasons mentioned above.

Thus, the authors can conclude that the use of a depot can increase the efficiency of the system. In this project the results were shown on the example of the city of Hamburg, the ratio of the effectiveness of the system with and without a depot. There are some important data for this example:

- In accordance with modern standards, the percentage of recycled materials in new materials cannot exceed 30% (according to DAfStb guideline [3] and DIN EN 206-1 (2001-07) ([6], Table 1).
- Construction is a seasonal activity and for simplicity, we will assume that there is a low (3 winter months) and high (9 other months) period, the difference between which is 2.25 times. These assumptions are based on the economic status of the construction industry [9].
- Our example, Hamburg is the city with a population of 1.8 million people (the second-largest city in Germany) and an area of about 750 km^2.

- The total consumption of mineral resources for all construction in the selected city is 14.9 million tons per year ([15], p. 12). In total, about 280 objects were built during the reporting period ([8], p. 153).
- On the other side demolition of buildings, in turn, does not have a pronounced seasonality, so we will assume that all demolitions occur evenly throughout the year [4]. For the state, for example, the number of demolitions is approximately 100 buildings per year ([8], p. 153). The total volume of extracted materials from demolished buildings is 5.29 million tons ([15], p. 12).

3 Results

The maximum possible volume of consumption of recycled material can be 4.47 million tons. In turn, the volume of material available for processing over the same period is 4.6 million tons. From the total volume of material, in conclusion the average annual volume of material that is used and produced is almost in balance (considering modern standards).

Looking at the total number of materials, it can be concluded that in the low period 0.191 million tons will be over-produced every month and 0.573 million tons for the entire low period. This volume of materials will be buried, which will lead to a deficit of the recycled materials for a "high period" with the same volume. Obviously, the use of a 0.573 million tons volume depot for this system will give the optimal usage of resources. In accordance with expression "1", it can be calculated that the efficiency will be "1" and "0.87". So, in the absence of other constraints, a relatively small depot could improve the system efficiency by 13%.

Then it can be analyzed an example with parameters closer to reality. To plot the volume of the depot, it is necessary to determine how the system parameters will change over time.

- Was taken the growth of recycling capacities of 10% per year.
- The increase in construction was taken be 1% per year.
- Suppose that a change in building standards occurs one-time (based on the trends of circular economy and resource efficiency described above) in 2025 from 30% to 70% [12, 14]. A lot of studies of researching group Construction recycling at the Brandenburg University of Technology has shown, that using till 50–70% and in some cases till 100% use of recycling aggregate has proven the same quality as normal concrete ([16], pp. 37–55). These study cases were for using recycling materials for new building. For road construction, percentage recycling materials is even higher than in building construction especially in gravel base layers ([2], pp. 8–12). Therefore we can assume that the standards will soon allow the higher proportion of recycling materials till 100%.
- Assumed that the number of demolishes do not change.

Supposed that all materials that are not used in construction will be stored in long-term storage depots. Based on these data, the graphs were constructed (Figs. 1 and 2).

The maximum volume of a long-term storage depot will be about 90 million tons, which is equivalent to almost four annual volumes of all consumption of mineral resources. The graphs clearly show that changes in the norms have practically no effect on the reuse of materials. In order for such an effect to be observed, the growth rate of processing facilities should be about 30% per year, and in this case, the total area of long-term storage depots will not exceed 30 million tons.

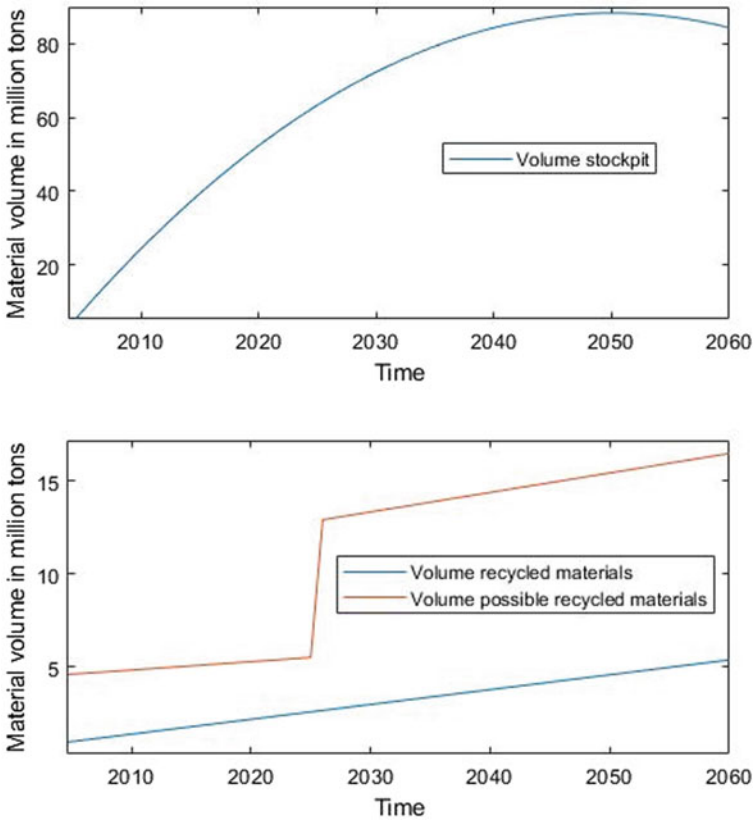

Fig. 1 Volume of accumulated materials in depot; volume of recycled materials; maximum possible volume of recycled materials potentially applicable in construction by growth of recycling capacities of 10% per year. *Source* Developed and compiled by the authors

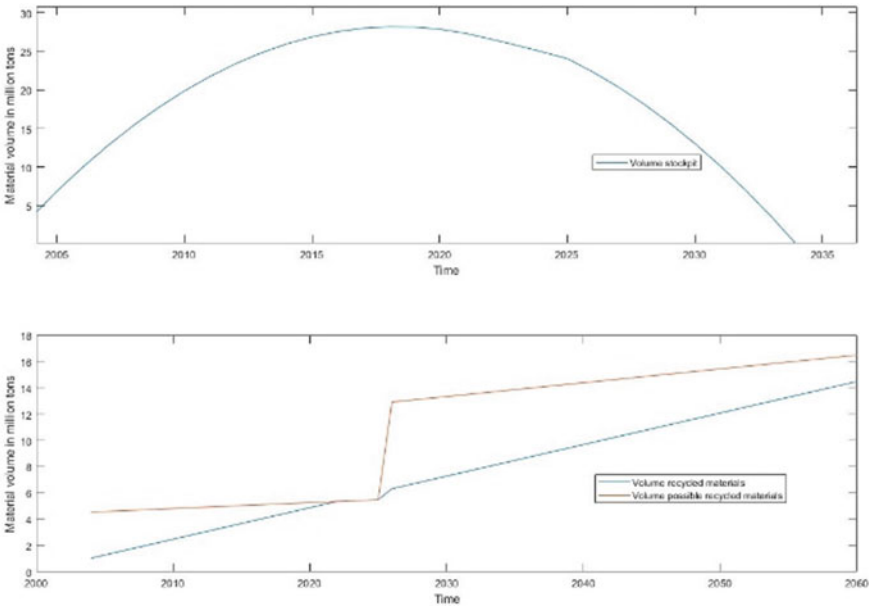

Fig. 2 Volume of accumulated materials in depot; volume of recycled materials; maximum possible volume of recycled materials potentially applicable in construction by growth of recycling capacities of 30% per year. *Source* Developed and compiled by the authors

4 Conclusion

The concept of long-term storage depots for mineral building materials can significantly increase the efficiency of the construction waste recycling system and can have a positive impact factor on the whole urban mining concept. A positive effect can be observed both at a time period of one year and at intervals exceeding a building life cycle (50–60 years).

The goal of this article is not to calculate a specific project of the presented concept, but we would like to indicate that the development of such kind project will include a comprehensive multifactor analysis. In the process of this analysis, it is necessary to answer exactly which parameters need to be optimized and it can be economic, logistic or environmental parameters. This work will require the use of machine learning and optimization algorithms. Therefore, before starting further research in this area, it is desirable to collect more statistical information, which is a separate complex task itself.

Tools to Smooth Regional Differentiation in the Digital Economy Formation Process

Zhanna A. Zakharova, Pavel N. Zakharov, and Andrey A. Cherkashin

Abstract The aim of the study was to assess the degree of differentiation of Russian regions with respect to readiness and involvement in the process of digitalization of the economy in order to find an adequate set of tools to smooth out these contradictions. To achieve this goal, groups of indicators were identified to assess the level of differentiation of regions regarding the readiness and involvement of regions in the processes of digitalization. At the same time, unlike the methods used to assess the level of digitalization of the regional economy, the authors not only compared the regions with each other, but also compared the actual values of indicators with the limit criteria (reference) values. As an empirical base of the study, data on nine regions of Central Russia, namely Moscow, Vladimir, Ivanovo, Kostroma, Kaluga, Nizhny Novgorod, Ryazan and Yaroslavl regions were used. As a result of the study, the features of differentiation of regions in the process of formation of the digital economy are determined, and the tools of its smoothing are determined.

1 Introduction

One of the requirements of the modern economy is the development of scientific and technological progress, the need to "keep up with the times", to invent and produce something new. Objectively, the regions of Russia are in the process of forming an innovative economy. This refers to the significant fact that the region is an open system and it is possible to distinguish its external environment, which is dynamically changing. Among the trends of changes in the external environment of the region can be attributed to the digitalization of the economy. At the same time, the ability of enterprises in the region to quickly introduce innovations into the practice of economic activity creates prerequisites for improving its competitiveness and sustainability [1]. At the same time, as it is known from the theory of the development of scientific and technological progress, the digitalization of the economy contribute to the growth of labor productivity and the release of labor in the sphere of material production and, accordingly, increase the growth rate of the sphere of intangible production, which is also one of the requirements of the economy. Moreover, the development of the sphere of intangible production and the growth of welfare of citizens contribute to the emergence of new types of intangible benefits [2].

In this connection, it is very important to study the possibilities of the region and the prerequisites that contribute to building the innovative potential of the region and the effective implementation of the national project "Digital economy". The term "digital economy", which appeared not in Russia today by many researchers is identified with a set of certain numbers in any direction, which leads to a shift in the productive forces and contributes to the change of all socio-economic relations [3]. It is noted that the transition to the digital economy is carried out from the fifth to the sixth technological mode. However, studies of the Russian Academy of Sciences show that the Russian economy is in the fourth technological mode with elements of the fifth. But this is the whole country. And if we consider the situation in the regions, we can say that due to the significant territorial differentiation in the economy of the regions, qualitatively different and poorly interacting technological structures are formed. At the same time, the intensification of innovative activities in the region could smooth out this kind of situation (the stratification of regions into various technological structures). However, there is a significant differentiation in the regions of Russia [4]. For example, in terms of the share of organizations engaged in technological, organizational, marketing and other innovations, the gap between the regions is 123.5 times according to 2017 (from 24.7% to 0.2%) and 284 times in terms of the share of innovative goods, works and services in the total volume of goods shipped, works performed, services (from 28.4 to 0.1%).[1]

The aim of the study was to assess the degree of differentiation of Russian regions with respect to readiness and involvement in the process of digitalization of the economy in order to find an adequate set of tools to smooth out these contradictions.

Table 1 Indicators of assessment of the level of differentiation of regions by readiness and involvement of regions in the processes of digitalization

#	Group of criteria	List
1	Indicators reflecting the level of entrepreneurship development	• Number of enterprises • Critical mass of entrepreneurs • Financial resources of enterprises • Share of unprofitable enterprises and organizations
2	Indicators reflecting the level of innovation in the regional economy	• Share of enterprises engaged in technological innovations • Share of innovative goods, works, services in the total volume of goods shipped, works performed, services, % of the total • Share of innovative products in regional exports
3	Indicators reflecting the level of development of the digital economy infrastructure	• Subscribers of broadband access to the Internet, • Proportion of households with access to broadband Internet • Proportion of the population using the Internet • Share of organizations using the Internet

2 Methodology

To achieve this goal, groups of indicators were identified to assess the level of differentiation of regions regarding the readiness and involvement of regions in the processes of digitalization. At the same time, unlike the methods used to assess the level of digitalization of the regional economy, we not only compare the regions with each other, but also compare the actual values of indicators with the limit criteria, in fact, with what the regions in question should strive for. These 3 groups of indicators are shown in Table 1.

As an empirical base of the study, data were used for nine regions of Central Russia, namely Moscow, Moscow, Vladimir, Ivanovo, Kostroma, Kaluga, Nizhny Novgorod, Ryazan and Yaroslavl regions.

3 Results

Undoubtedly, an important point for the introduction of digital technologies in business is the presence in the region of the institutional environment in which these technologies are born and implemented. What makes the entrepreneur to implement the technology? If he doesn't, he'll go bankrupt. Not some indicators that he has established, how many technologies need to be implemented or how many digital technologies need, but he simply has to, as if he does not implement, he will leave

the market. So, according to theory K. Marx's "Capitalist, applying an improved method of production, assigns in the form of surplus labor most of the working time than the rest of the capitalists of the same branch of production. This very law, as a compulsory law of competition, forces our capitalist's rivals to introduce a new method of production." (Marx 5).

At the same time, the creation of a competitive economy primarily involves the presence of a certain critical mass of entrepreneurs, in the words of J. Schumpeter, innovative entrepreneurs, "pulling" significant financial resources in order to create the most effective technologies (including technologies of the digital economy). At the same time, attention should be paid to whether there is a "critical mass of entrepreneurs" in the regions of the Russian Federation and in what conditions of the economy it operates and whether this moment contributes to the emergence of business, whose talent will be directed to the necessary innovative transformations.

Based on the statistical data on the socio-economic development of the regions of the center of Russia, it should be noted that in terms of the number of enterprises and organizations in 2017, there is a decrease in all the regions we study (Table 2).

Thus, according to the table it can be said that in such regions as Vladimir, Ivanovo, Kaluga and Moscow regions until 2015 there was an increase in the number of enterprises and organizations. In 2016, only the Nizhny Novgorod and Yaroslavl regions maintained the growth trend for this indicator, and in 2017, there was a decrease in the number of enterprises and organizations in all the studied regions.

Table 2 Number of enterprises and organizations, units (at the end of the year)

Region	2005	2010	2013	2014	2015	2016	2017
Vladimir region	27,868	35,952	35,383	35,413	35,718	34,662	32,376
Ivanovo region	29,121	32,341	32,911	34,453	35,612	34,209	31,698
Kaluga region	27,880	27,135	27,462	28,157	28,634	27,930	26,696
Kostroma region	17,274	17,407	18,060	17,642	17,836	17,256	16,464

Table 3 Indicator of the critical mass of entrepreneurs in the regions of the center of Russia

Region	2005	2010	2015	2016	2017
Vladimir region	53.3	40.0	39.1	40.1	42.3
Ivanovo region	37.8	32.8	28.9	30.0	32.0
Kaluga region	36.7	37.2	35.2	36.3	37.9
Kostroma region	40.5	38.3	36.5	37.6	39.0
Nizhny Novgorod region	39.0	36.1	31.0	30.0	34.1
Ryazan region	37.3	34.2	33.3	34.6	37.6
Yaroslavl region	31.9	28.2	27.1	26.9	27.9
Moscow region	34.7	31.6	28.1	30.1	31.3
Moscow city	9.0	10.0	10.5	12.2	12.5

Compiled by: Regions of Russia [6], pp. 39, 48, 554, 555

Also, in theory and practice, it is noted that in a market economy, the normal indicator by which one can judge the "critical mass of entrepreneurs" is the ratio of the population of the territory to the number of enterprises and organizations 10-15 to 1. That is, the best indicator is when one organization has 10–15 people of the population.

However, according to Table 3, it should be noted that the above criterion is achieved only in the city of Moscow, and in the regions we study, this figure is 2–3 times lower than the optimal value, which indicates a lack of entrepreneurs in the regions of the center of Russia. In addition, the deterioration of this indicator by region over the past year is likely to indicate an inefficient institutional environment that hinders the development of business. At the same time, high optimal indicators of the critical mass of entrepreneurs (Moscow city) may indicate that in these regions the institutional environment for business is of the highest quality and, consequently, many issues of socio-economic development can be solved in the region.

A very important factor for the development of innovation (digitalization) in the region is the availability of investment capital from entrepreneurs? That is, whether the business in the regions of the center Is necessary to see the financial results of enterprises, the share of loss-making enterprises (Tables 4 and 5).

Thus, according to Table 4 in such regions as Vladimir, Kostroma, Ryazan, Moscow regions for the period from 2016 to 2017, the financial results of the organizations decreased, and in the Ivanovo region, although there is an increase in these results, but they are very small compared to other regions (about 1.6 billion rubles). These points, as well as an increase in the share of unprofitable enterprises in the regional economy (Table 5) suggest that the enterprises of the region reduce the possibility of investing at their own expense, and a third of enterprises have this opportunity (to develop at their own resources, namely to invest in renewal and innovation) at all. In this regard, we can say that these trends constrain the innovative capacity of the business (the business has no sufficient private capital for the implementation of innovation activity and the introduction of digital technology).

Table 4 Financial results (profit minus loss) of organizations, million rubles

Region	2013	2014	2015	2016	2017
Vladimir region	22,055	18,951	31,117	36,601	32,668
Ivanovo region	−2,670	−1,632	−2,797	−200	1,594

Table 5 Share of unprofitable enterprises, % of total number of enterprises

Region	2013	2014	2015	2016	2017
Vladimir region	30.2	33.0	34.5	30.3	31.4
Ivanovo region	33.2	37.3	40.3	40.5	39.1
Kaluga region	31.0	34.8	34.8	31.4	30.8
Kostroma region	37.0	35.9	35.6	31.8	42.9
Nizhny Novgorod region	28.2	31.2	31.6	31.1	28.5
Ryazan region	27.3	25.0	24.6	28.0	24.8
Yaroslavl region	40.1	38.4	36.6	32.8	33.8
Moscow region	30.5	30.8	30.2	25.4	30.2
Moscow city	31.5	35.4	34.3	29.5	33.9

Compiled by: Regions of Russia [6], p. 1054

Thus, according to Table 5, a high proportion of unprofitable enterprises in 2017 is observed in such regions as Kostroma (42.9%), Ivanovo (39.1%), Yaroslavl (33.8%) regions. The optimal value of this indicator is 20% [7].

In confirmation of the fact that the lack of own funds constrains the innovative activity of enterprises in those regions where there is the highest proportion of unprofitable enterprises (Kostroma and Ivanovo region and minor financial results of organizations, there is the lowest among the regions of the share of organizations engaged in technological innovation (Kostroma 2.8%, Ivanovo—4.2%) (Table 6).

Besides, in many regions of the center of Russia the share of innovative goods, works, services in the total volume of the shipped goods, the performed works, services is not significant, and also differentiation of regions on this indicator is observed (Table 7).

Thus, according to Table 7 in the regions of the center of Russia, the gap in the values of the share of innovative goods, works and services in the total volume of

Table 6 The share of organizations engaged in technological innovation, % of the total

Compiled by: Regions of Russia [6], p. 946

Table 7 Share of innovative goods, works, services in the total volume of goods shipped, works performed, services, % of the total

Region	2013	2014	2015	2016	2017
Vladimir region	9.4	8.3	9.6	5.8	8.1
Ivanovo region	0.5	0.9	1.5	0.2	0.2
Kaluga region	3.6	2.7	3.2	2.7	2.7
Kostroma region	1.9	2.0	1.8	6.7	9.9
Nizhny Novgorod region	18.1	21.3	15.8	16.5	15.4
Ryazan region	2.8	3.2	3.5	6.2	6.8
Yaroslavl region	9.3	10.5	7.0	14.9	12.2
Moscow region	12.7	12.9	13.7	15.8	14.7
Moscow city	15.3	11.0	17.1	13.6	3.3

shipped goods, works and services is 73.5 times, namely from 14.7% in the Moscow region to 0.2% in the Ivanovo region. According to L.I. Abalkin, the minimum value of this indicator from the point of view of safety should be 15% [8]. However, only Nizhny Novgorod (15.4%), Moscow (14.7%) and Yaroslavl (12.2%) regions are close to this criterion.

Significant differentiation is also observed in terms of the share of innovative goods, works and services in the total volume of shipped goods, performed works, services, industrial production organizations (Table 8).

Thus, according to the table, the gap in the values of the indicator is 158.0 times, from 15.8% in the Nizhny Novgorod region to 0.1% in the Ivanovo region. At the same time, the critical limit value of this indicator according to the indicators of S.Yu. Glazyev should be 15–20% [9]. However, this criterion is achieved only in the Nizhny Novgorod region. A very controversial point is that in the city of According to the data for 2017, the value of this indicator, as well as the indicator of the share of

Table 8 Share of innovative goods, works, services in the total volume of shipped goods, performed works, services, industrial production organizations, % of the total

Region	2013	2014	2015	2016	2017
Vladimir region	7.1	6.2	8.0	5.4	6.6
Ivanovo region	0.5	1.0	1.5	0.2	0.1
Kaluga region	2.0	0.8	1.2	1.1	1.0
Kostroma region	1.7	1.8	1.4	6.8	10.4
Nizhny Novgorod region	17.5	18.2	13.1	17.7	15.8
Ryazan region	2.9	3.2	3.2	5.6	6.8
Yaroslavl region	9.4	10.0	7.0	16.4	12.9
Moscow region	9.4	8.6	8.3	10.0	8.4
Moscow city	17.8	11.0	19.8	15.7	1.2

innovative goods, works and services in the total volume of shipped goods, performed works and services, is at a low level of 1.2 and 3.3%, respectively. This point is most likely due to the significant withdrawal of industrial production outside the city of Moscow, which is reflected in the low level of the share of innovative goods, works and services in the region's exports (0.7%) (Table 9).

Thus, according to Table 9, the share of high-tech exports is the highest in such regions as Moscow (50.8%) and Yaroslavl (42.0%) regions. At the same time, in the regions there is also a significant differentiation in this indicator for 2017 in more than 500 times from 50.8% in the Moscow region to 0.1% in the Ivanovo region. At the same time in such regions as Vladimir and Kaluga regions in comparison with 2013 there is a decrease of almost 2 times. At the same time, according to some researchers, the optimal value of the indicator should be 40–50%. According to the data of Monitoring the development of the information society of the Russian Federation, the value of this indicator in the whole country in 2017 amounted to 7.5%, and in 2013-14.1%. And, for example, in 2012, the share of innovative goods,

Table 9 Share of innovative goods, works and services in exports of goods, works and services, %

Region	2013	2014	2015	2016	2017

Compiled by: Regions of Russia [6], p. 878

works and services in U.S. exports was 60.7%. Comparison with this criterion will reflect even more significant differentiation of regions by the considered indicator.

In addition to the indicators of the "critical mass of entrepreneurship" in the regions, the innovative activity of this entrepreneurship and its resource availability, an important aspect of the digital economy is the availability of quality infrastructure. So, if we turn to the data of Rosstat, in terms of "Organizations that have a website" a small part of the regions exceeds the mark of 60%. On the selected studies of us regions, the highest rate in Moscow is 66.8%, the average for Russia it is of 47.4%. At the same time, for example, in Finland, this figure is 95% of the total number of organizations in the business sector. In terms of "the Number of personal computers per 100 employees (with Internet connection)" even in Moscow, the value is 59 people. Other regions of Central Russia have a close value to the figure in the whole of Russia—33. A small indicator in almost all regions does not allow us to talk about the readiness of even the most basic conditions for a new economic system. Some indicators reflecting the level of development of the digital economy infrastructure in the Russian regions are given in Tables 10 and 11.

There are also some figures reflecting the level of development of the digital economy infrastructure in the regions of the Russian Federation, which are presented in the study "Indicators of the digital economy" (Table 11).

According to the data of Table 11 on indicators reflecting the level of development of the digital economy infrastructure in the regions we study, there is no high differentiation, but at the same time, in the Kostroma region the share of organizations using broadband Internet is 73.1%, in the Moscow region is only 80.6%. The share of households with access to broadband Internet in the Ryazan and Vladimir regions is the lowest of the studied regions and amounts to 63.9% and 67.6%, respectively, although the value of this indicator laid down in the National project "Digital economy of the Russian Federation" should be 97% by 2024.

Table 11 Indicators reflecting the level of development of the digital economy infrastructure in the regions of Russia

Region	Broadband Internet access subscribers per 100 people		Proportion of households with access to broadband Internet, %	Share of organizations using broadband Internet, %
	Fixed	Mobile

Kaluga region	24.8	81.5	76.5	86.6
Kostroma region	20.8	67.2	78.4	73.1
Nizhny Novgorod region	23.3	80.9	78.7	90.3
Ryazan region	23.5	67.5	63.9	90.0
Yaroslavl region	23.5	73.9	79.4	89.6
Moscow region	19.6	114.1	92.8	80.6
Moscow city	33.1	114.1	91.3	95.2

Compiled by: Indicators of the Digital Economy [10]

4 Conclusions

As shown by the study:

- the differentiation of regions observed and increasing in some indicators creates a risk of lagging behind the leading countries in terms of digitalization in the Russian Federation as a whole;
- we selected the regions most differentiations on indicators that reflect the level of innovativeness of the regional economy and level of enterprise development. In many ways, the development of these factors, that is, innovative entrepreneurship depends on the quality of the institutional environment. Therefore, the tools for the development of the digital economy in the regions under consideration should be primarily aimed at smoothing out these negative aspects. First, it is necessary to adjust the policy documents reflecting the process of state regulation of the digital economy formation to take into account the specifics of a particular region. In regions with insufficient innovation activity and low level of development of innovative entrepreneurship, additional measures of support from the state (subsidies, tax incentives) are needed. Secondly, a national plan for the development of competition and additional guarantees from the state for the protection of private property is needed in view of the fact that the lack of protection of innovative business can constrain the motivation for the introduction of digital technologies;
- in the future, when developing a methodology for assessing the level of digitalization and the degree of differentiation of regions by integrated indicators of the digital economy, it is necessary to take into account international experience in relation to the used indicators of evaluation. So. For example, in the United

States, PWC conducted a study on the future of digital technologies and identified as key indicators the share of enterprises expecting a doubling of the digital technology market and the share of companies focused on innovation that have achieved significant cost savings through digitalization. At the same time, putting the forecast of these indicators in the US, the following criteria were noted: 72% of us companies expect a doubling of the digital technology market and 27% of companies will achieve a significant reduction in production costs due to digitalization, while the combined savings from the introduction of digital technologies in 2020 will amount to $ 421 billion.

Estimating Scientific and Technological Competitive Advantages: Study of Foreign Approaches, Type Classification of Business Entities and Influencing Factors

Evgeniya L. Moreva, Lyudmila V. Obolenskaya, and Antonina V. Sharkova

Abstract ***Purpose***: The paper is aimed at designing the specific-organized typological structure of economic entities through the study of foreign approaches and revealing the influencing factors in developing scientific and technological competitive advantages. ***Design/methodology/approach***: From the perspective of discovering the place and role of science, process, and technology, we have carried out a retrospective comparative analysis of the basic concepts of competitive advantages. We have shown that peculiarities of different types of business entities as actors of competitive advantages are underestimated in these concepts. Relying on an integrated analysis of documents and academic sources, we have suggested a typological structure of business entities. It includes types of industry entities that possess high potential for the development of industrial policy measures on scientific and technological competitive advantages. To arrange and bring together the heterogeneous types of industry entities occurring in various information sources, we have highlighted five generalizing typological features, in particular, the specific nature of the space-industry borderlines of the company's activity, the time-dimension framework, competitive strategies, and business models. Also, we have performed a content analysis of various sources to uncover the main factors that influence scientific and technological competitive advantages. We especially emphasized the certain level of the country's socio-economic development as a factor of the successful development of top technologies. ***Findings***: It is recommended to take into consideration the suggested typological structure in developing industrial policy measures on scientific and technological competitive advantages, including ones to counter the occurring

1 Introduction

The problem of competitive advantage (CA) has historically foregrounded in international economic research and business practice and has become even more acute in the context of the digital economy. The relevance of engaging science, process, and technology in production has also been highlighted in numerous and diverse opinions on CA.

The study of such complex phenomena has been challenged by the obstacles that many scientists faced when solving the problems of assessment and utilization of CA as such. Hence, we see differences in the place assigned to science, process and technology in these concepts and as a result the inconsistency of the conclusions. This uncertainty evoked the need to establish a steady foundation, in relation to which CA are being developed, as well as factors influencing this process.

2 Materials and Method

The above-named problems predicated the consistency of stages of the research on scientific and technological competitive advantages conducted in this article:

(1) investigating the opinions on the place and role of science, process, and technology in the basic CA concepts; justifying the feasibility of classifying different typological groups of entities acting as bearers of scientific and technological competitive advantages;
(2) designing a specific-organized typological structure that involves types of industrial entities with high potential for the development of industrial policy measures on scientific and technological competitive advantages;
(3) discovering the main factors influencing the development of these competitive advantages.

3 Findings

Finally, we have obtained the following findings.

(1) From the perspective of discovering the place and role of science, process, and technology, we have carried out an analysis of the main current CA concepts and have found out that the peculiarities of different types of economic entities as CA actors are underestimated in them.

In management and business literature, the first integrated assessments of CA are usually associated with the Market-Based View, or the school of self-representation according to which the company's behavior is determined by external forces and, above all, the industry structure. It makes companies to be responsive, develop and take relevant strategies that predetermine the company's behavior.

In this context, R&D played the role of one of the factors, the state of which should be regarded when developing and taking the company's strategy along with its goals, anti-competitive practices, advertising, etc.

The well-known concept of the 5 forces by M. Porter was similar to this approach. But in contrast to the common view on consideration of corporate strategy exclusively as reactive, the author also allowed the aggressive position of companies concerning industry structure. After all, they were an integral part of this structure, acted and entered into competitive relations within it.

However, like in the common case, M. Porter assigned to science, process, and technology the role of area or direction referring to which the company will be able to develop CA for itself, but does not substitute it [1].

Closer attention to science, process, and technology in the system of competitive relations is paid in the resource-based concept of the company. Within it, the company is seen as a total of valuable, rare, non-replaceable resources that are of critical importance whether the company gains a competitive advantage or not. Besides, the authors focused on the variety of physical resources and intangible abilities of the company that are strategically important, also in the competition. Among these resources and abilities, a special place was given to information and knowledge.

However, it is specific that if some researchers deemed knowledge as an ordinary resource (Murray; Tiis; Tiwan, et al.), then others thought otherwise. It has unique properties that distinguish information and knowledge from the rest [2]. For some time, Evans and some other authors who later adhered to other positions have a similar standpoint [3].

The differences in the above standpoints did not prevent the authors from the unanimous interpretation of these resources as ones of an organizational nature. At the same time, researchers differently interpreted specific forms of expressing organizational knowledge.

Some addressed information and know-how; others highlighted data, information, knowledge, expertise, and abilities; the res stressed core, advanced and new knowledge. With all of them, the authors associated the prospects of launching a new product and, thanks to this, a favorable market position that would provide for the company's superiority over competitors and leadership in the mark.

The idea of the special role of knowledge in creating and cementing the competitive position of the company was further developed in a competency-based approach to CA.

The competences were understood as the company's ability to allocate resources in a specific way and integrate them for getting the expected result. The authors emphasized the informational origin of abilities, their unique nature in every particular company, as well as the long-term effects from their development and employment.

The concept of dynamic and organizational abilities was widely known in this area. It assumed the companies to combine and rearrange them in response to changes in the corporate environment [4].

An illustrative example of this position was the concept of key competencies by Prahalad and Hamel who linked the development of CA with managers' managers on the integration of corporate technologies and industrial skills in competencies, and, hence, the company will be able to effectively adapt to environmental changes [5].

Adherents of the relational approach, who focused on the company's contacts with local network structures, shared different views. They believed that companies using developing science and information technologies get the opportunity to take advantage of their participation in networks to cement the position in the market, gain revenue and win CA. This effect is achieved due to the specific property of networks to provide equilibrium between its participants, regardless of the form.

Such a variety of approaches to CA did not mean a special emphasis on science, process, and technology as elements of assessment, development, and utilization of CA. This notion was still unclear, which caused a widespread statement about the persistence of the CA assessment problem. Endeavors to solve it completely and thoroughly have appeared to be fruitless, despite the imperatives of business practice.

In both theoretical and practical terms, it is required to identify a steady foundation to estimate the behavior of business entities that more or less successful in developing and/or utilizing CA.

(2) We have designed a specific-organized typological structure, involving types of industry entities that have a high potential for the development of industrial policy measures on scientific and technological competitive advantages.

In order to arrange and bring together the heterogeneous types of industry entities occurring in various information sources, we have highlighted five generalizing typological features. As a result of the analysis and classification of information, we identified five generalizing features typical for industry entities:

- the peculiarities of the space-industry borderlines of companies;
- the specific nature of the dimension-time framework;
- the particular nature of competitive strategies and business models;
- peculiar utilization of resource opportunities;
- institutional and legal particularities.

In view of the identified features, we designed the upper level of the typological with five blocks. We can put various types of industry entities with high potential for the development of industrial policy measures into these enlarged structural

blocks. Additionally, following the accepted standards for the design of classification-typological structures, we have reserved another structural block "all the rest" for the subsequent recognition of the types of industry entities with properties that haven't been expressed at this stage.

Let's provide examples of types of industrial entities that can be referred to enlarged structural blocks.

Thus, the following entities can be referred to the enlarged structural block "types of industrial entities, classified by peculiar space-industry borderlines" (the second level of the typological structure):

- companies of a particular industry;
- process manufacturing companies of a particular technological effectiveness (high-tech; mid-high-tech; mid-tech; low-tech);
- companies of a particular region;
- companies selling products in particular markets (local or regional; national; international), etc.

If we take Russia as an example, then it is appropriate to use for classification of industry entities in terms of industry peculiarities the All-Russian Classifier of Types of Economic Activities OKVED2 [6] applied in the system of national statistical monitoring. This classifier is harmonized with the international classifier of types of economic activities NACE Rev. 2 [7], which allows making international comparisons. It should be mentioned that the OKVED (previous editions) replaced the industry classification (the All-Russian Classifier of the Sectors of the National Economy (OKONKh)).

For classification of the types of industrial entities in accordance with regional peculiarities, it makes sense to use the all-Russian Classifier of the Administrative-territorial Entities OKATO [8]. This classifier, as well as OKVED2, is used in the system of national statistical monitoring, which makes it possible to identify and digitalization of the types of industrial entities under consideration by relevant indicators.

The enlarged structural block "types of industry entities, classified by specific competitive strategies and business models" (the second level of the typological structure) can include:

- companies pursuing particular business models according to McKinsey (based on science, engineering, consumer, and efficiency) [9];
- companies exercising strategies of catching-up" development of certain evolutionary stages according to Golichenko ("picking up" technologies, incremental technological advances, gaining the technological leadership or his successor) [10], etc.

The following companies can be attributed to the enlarged structural block "types of industrial entities classified by institutional and legal peculiarities (the second level of the typological structure):

- companies of a particular legal corporate form;

- companies using particular methods of intellectual property protection (formal and informal), etc.

The regard of the legal corporate form is important, for example, for the informational orientation of the small business. In work by Allen [11] it has been argued that the right choice of legal corporate form at different development stages of companies engaged in science and technology can contribute to their competitive advantages. On the contrary, the wrong choice can slow down the processes under consideration. Moreover, the legal corporate form should not be a static solution.

It should meet the company's needs at different stages of the life cycle starting from the preparatory stage (R&D and pre-launch) to entry to the market and release of products. As the company grows, it may come to a point where the current legal form will no longer able to solve the tasks. The choice of the best version of the legal corporate form depends on:

- what level of protection from personal property and financial accountability is needed;
- whether a long term when the company may suffer losses is possible;
- whether it is required to increase capital through venture investment and the issue of shares of various types;
- what tax deduction pattern is acceptable.

Contingent on the types of companies, critical factors that hinder the development of scientific and technological competitive advantages is of different hazard. For example, Obolenskaya [12] by the example of Russia has demonstrated and assessed these differences for companies classified by industry, regional peculiarities, the measure of producibility, the number of employed. Accordingly, different measures of industrial policy will be critical for the development of scientific and technological competitive advantages in different types of companies.

In general, the designed typological structure can be regarded as some basis open for future development and intended for the informational provision of industrial policy measures on scientific and technological competitive advantages.

(3) The examination of approaches to research and development and scientific-technological activity allowed the authors to estimate the essential level of socio-economic development of the country as a factor of successful top technologies (Table 1).

Currently, there is no uniform approach to the classification of factors and the nature of their impact on competitive advantage. As a rule, there has been distinguished technological, resource, global, innovative, organizational and structural, and cultural advantages [13].

Organizational and structural factors include:

- restructuring of the business through the sale of unpromising and unprofitable companies;
- simplification of the production component;

Table 1 The essential level of the country's socio-economic development as a factor of successful top technologies [18]

Technology designation	Required level of a country's development
(1) Wireless communication for the countryside	Low
(2) Cheap solar energy	
(3) Genetically modified grain crops	
(4) Filtration and water treatment technologies	
(5) Cheap autonomous supply of houses	
(6) Reduction of waste and toxic emissions in production	Average
(7) Hybrid vehicles	
(8) RFID (radio frequency identification) of goods and individuals	
(9) Methods of rapid detection of bio-substances	
(10) Nanomechanics of drug delivery to sites	High
(11) Sophisticated methods of diagnostic assessment and surgery	
(12) Quantum cryptography	
(13) Ubiquitous information	Advanced
(14) Production of living tissue for implantation	
(15) Wearable computers (like jewelry, clothes, etc.)	
(16) Universal enhanced security sensors	

- mergers and acquisitions of the business;
- globalization.

In the scientific community, there are various approaches to the classification of factors. For example, Fatkhutdinov [14] classifies factors as external (that don't depend on the company's activities) and internal (managed by the company). Vihansky [15] determines external factors, surrounding factors, and the internal environment factors. I.U. Zul'karnaev and L.R. Il'yasova divide factors into three groups (the goals of the company, resources, and environmental factors) [16]. A.A. Thompson and A.J. Strickland suggest treating product quality, costs, financial resources, and the application of innovative technologies as competitive advantages [17].

The exploration of the above proceedings made it possible to classify factors into internal ones that depend on the company's activities and external ones. It is worth noting that the key internal factor is the innovative activity of the company since it is an innovation that contributes to the scientific and technological competitive advantages.

In general, the key factors that have an impact on scientific and technological competitive advantages of Russian companies are somehow related to the policy on

research and development and science and technology both in the company and the federal and regional authorities. These factors are

- higher provision of enterprises with modern equipment and processing technology;
- a highly skilled staff of enterprises;
- state-funded development of modern types of equipment samples within the state armament program;
- granting subsidies to the enterprises in terms of federal targeted programs and state guarantees for loans sought;
- high reliability of cooperative ties with enterprises-co-contractors of the state order;
- high quality of manufactured products thanks to a special mechanism for the acceptance of goods (primarily under participation of military representative offices of the Defense Ministry);
- staff's key competencies that provide conditions for a rapid launch of products on the global market.

4 Conclusion

(1) In order to completely overcome the inconsistency of the basic CA concepts that have emerged in economic theory, also in connection with the higher engagement of science, process, and technology in production, it is reasonable to address them taking into account the different types of entities that capable and ready to take these advantages in a greater or a lesser extent.

(2) The types of industrial entities presented in the developed typological structure are recommended to be respected when developing industrial policy measures on the development of scientific and technological competitive advantages, including ones to counter the occurring obstacles. A differentiated approach regarding the different importance of measures for different types of industrial entities will enhance the performance of the industrial policy.

(3) The development of research-development and science-technology competitive advantages have an impact on whether Russia succeeds in facing the major challenges and the digital agenda. The situation requires the deployment of all new economic tools and intensify the show of new groups of factors. Along with that, there are factors constraining the development of competitive advantages. When assessing such factors in industrial enterprises, it is necessary to take into account their dependence on the industry which the enterprise belongs to. A constraint or obstacle may have a different hazard for different industries. In this regard, the peculiarities of the industry specifics should be bore in view when developing scientific and technological competitive advantages.

Recursion of the Temporal Paradigm of the Digital Economy Accounting

Roman S. Blizkiy, Valentin E. Malinenko, and Yulia S. Lebedinskaya

Abstract The article reviews the features of the transformation of accounting in the digital economy. The research results of foreign and domestic authors are considered. The regulatory analysis of the legal acts regulating the digital economy space of the Russian Federation and the Eurasian Economic Union was conducted. The main tasks, trends and regularities of development of digital features have been established. The research is aimed at systematization of elements of temporal accounting paradigm in conditions of digital economy. The results are the following: (1) The terminological apparatus of "temporal paradigm" concept is revealed. (2) The recursion of graphical model of temporal features of digital economy accounting is presented. (3) The elements of temporal features of exogenous format of action in digital economy are systematized.

recursive fluctuations of processes, including those connected with introduction of the digital unified platforms, blockchain technologies, use of the Big Data, cloud calculations changes a role of the accountant and coherence of his or her "classical" functions, requirements of the accounting and information environment of the organizations, properties and specificity of reflection of the facts of economic life. In his treatise "Treatise on Accounts and Records", Luca Pacioli laid the foundation for accounting by describing the nature of double entry, the purpose of accounting, its postulates and main processes. Today, the format of digital transformation and the level of technology are rapidly approaching the time of change in the revision of the accounting concept. For example, the forms and processes for the generation of accounting information are simplified, accounting guidelines are unified in accordance with unified international accounting standards, a model chart of accounts was introduced in 2001, an electronic digital signature has been implemented since 2019, etc. There is a situation when it is necessary to simulate the proactive position of future accounting, as financial, social, tax, legal responsibility entrusted to the functional space of the functions of an accountant, demands so.

2 Reference Information and Methodology

According to research by Skolkovo experts [1], the accounting profession is becoming obsolete intellectual profession, and by 2030, with the development of technology and transformation of digital economy, it will have disappeared from the nomenclature of jobs. In return, there will be designers, coordinators, eco-auditors, trend-watchers, etc. Therefore, it is necessary to study the temporal paradigm of accounting in the digital economy thoroughly, using the following methodological tool—systemic and complex approach to study the temporal characteristics of digital transformation of accounting in dialectical unity with the development of the world economy. In the work the general scientific and special methods were used, which allowed to define the components, processes and interaction of historical achievements and views of transformation of accounting paradigms and to highlight the essence of the temporal paradigm. Particularly, the system approach and institutional-evolutionary method were used in determining the features and problems of the core of the concept of accounting. The graphical method was used in the study of the recursion of the graphical model of temporal features of accounting for digital economy. Preparation of proposals and recommendations required the use of the systemic structural method.

3 Discussion and Results

In response to the global financial and economic crisis of 2008, the G20 took over the task of finding and coordinating solutions to global economic problems. Since 2016, the G20 has been actively searching for global growth trends, international

legal regulation initiatives, overcoming problems and promoting the development of the digital economy to stimulate inclusive economic development [2].

At the international summit SDG (Sustainable Development Goals)—Challenge 2019, the head of the international network of companies "PricewaterhouseCoopers" Robert Moritz noted that by 2030 jobs will have become more and more automated, and new technologies, management models will transform production, and capital will displace people. Thus, he estimated that jobs in the UK (30%), USA (38%), Germany (35%) and Japan (21%) will fall into the zone of risk of such a transformation until 2030. In addition, 53% of workers who will face change (automation) will have their outdated competencies substantially rebuilt and new requirements created in their work [3]. The results of the presented initiatives of the World Economic Forum in Davos (WEF) in 2019, formed as part of the Strategic Intelligence Platform "Digital Economy and Society", initiate six key features that influence the trends and prospects of the digital economy. In addition, experts from the World Economic Forum estimate that by 2022, 60% of the world's GDP will have been digitized, and the world's population does not believe it will make life easier [4].

Since 2018, the Institute of Legislation and Comparative Law under the Government of the Russian Federation has been working on the development of a "Concept for the comprehensive regulation of relations arising from the development of the digital economy" with the enforcement of the foundations laid down by Federal Law No. 172-FZ of 28 June 2014 "On strategic planning in the Russian Federation" [5]. In addition, the actualization of the research direction is conditioned by the passport of the federal project of the Russian Federation "Normative regulation of the digital environment", approved by the Presidium of the Government Commission on Digital Development of the Russian Federation [6], where, in particular, the tasks have been defined out of many directions:

- provision of access to data storage and processing services throughout Russia, storage and processing of information created by state authorities and local governments in a single cloud platform;
- development of functionality for intellectual support of accounting and registration actions.

Changes in the process information support system, in which accounting traditionally plays a significant role, are proposed by the regulations:

- Strategy for development of information society in the Russian Federation for 2017–2030, approved by Presidential Decree of 09.05.2017 No. 203 [7];
- Presidential Decree No. 204 of 7 May 2018 on national development goals and strategic objectives for the period up to 2024 [8, 9];
- National strategy for the development of artificial intelligence for the period until 2030, approved by Presidential Decree of 10.10.2019N 490 "On the development of artificial intelligence in the Russian Federation".

According to estimates of experts from the National Research University 'Higher School of Economics', based on available statistics, gross domestic expenditures on the development of the digital economy in 2018 amounted to Rb 3795 billion rubles,

or 3.7% of GDP. Their volume in comparable prices increased by 3.5% as compared to the previous year [10].

The development of accounting paradigm theory is significantly influenced by philosophy, in particular, by T.S. Kun's scientific works, where he noted that scientific knowledge develops in a leapfrogging manner, through scientific revolutions. In addition, he singled out a "pre-paradigm" stage in the development of science, and then a chain of alternating periods of normal development and crises. In the scientist's opinion, a paradigm is a set of rules that guide the scientific community to set tasks. A paradigm is also a scheme or rule that is used to explain or interpret results [11].

The work of Australian scholar Murray Charles Wells on the formation of accounting history also pays considerable attention to the essence and properties of the accounting paradigm. Highlighting seven paradigms (anthropological, conjunctural, event, procedural, idealized, informational, and behavioural), M.C. Wells defined different criteria and attributes of their classification, ranging from the practice of an accountant, management processes, financial results, reflection of the facts of economic life and up to the study of behaviour, the final decision makers in the field of accounting policy [12].

The dualistic position with regard to the formation of content to the processes surrounding accounting is highlighted in Rene Savatier's scientific works, in particular his book "Theory of Obligations". Thus, in Chap. "Blockchain Technologies as a Reflection of Modern Reality: Diversity of Opportunities Versus Security Risks" 'Legal and economic viewpoints', the author notes: "In one and the same act, lawyers see mainly a legal action in the form of an agreed will, while economists see a movement of values" [13]. Hence, when forming an accounting paradigm, it is necessary to take into account both legal peculiarities of its implementation and economic aspects of efficiency.

E.I. Zuga's scientific view on the history of formation and evolution of accounting paradigms deserves attention. The six models proposed by her are worth considering and based on the derivative states of three methodological paradigms: unigraphic, digraphic and cameral. At the same time, the author has proposed, in our opinion, a rather narrow model of criteria of her paradigms, which cover not all objects of accounting [14].

Special attention should be paid to the approaches to the problems under consideration and to the review of the issues of accounting paradigm change in the discussion platform proposed by N. A. Kamordzhanova, Doctor of Economic Sciences, where the author examines changes in technology, digital economy, how they affect accounting and lead to a change in accounting paradigm [15].

Setting of scientific problems and elaboration of initiatives in the conditions of development of digital economy in the last decades are actively researched by domestic and foreign scientists, including questions of theoretical features of introduction and realization of economic and legal bases. Among them it is possible to highlight:

T. M. Odintsovo, here the author proposes a conceptual model of accounting, which includes a set of theoretical constructions that determine the logic, structure and principles of functioning of an accounting system in the digital economy [16];

R. H. Ilyasov in the study of spline-modeling and analysis of interrelations in the economy emphasizes the need to take into account the instability of forms of relationships, changes in the number of factors and the degree of their mutual impact. He also offers methods of "new econometrics"—for modeling systems with variable structure with connection of analysis of interrelationships of processes [17].

Table 1 presents an adaptive assessment approach to the content and structure of features that affect the development of the digital economy. Examining the peculiarities of transformation of accounting of the Russian Federation in the conditions of digital economy, it is necessary to note its close, integrative connection with the regulatory and legal space of the Eurasian Economic Union, under the aegis of which the unification of the process in the development of common approaches and rules of transformation in the field of digitalization among all participants of this union is carried out.

Thus, according to the decision of the Eurasian Economic Union of October 11, 2017 No. 12 "On the main directions of implementation of the digital agenda of the Eurasian Economic Union until 2025", the main directions are the digital transformation of economic sectors and cross-industry transformation, digital transformation of markets for goods, services, capital and labour, digital transformation of integration management processes, development of digital infrastructure and security of digital processes.

The dynamics and trend of changes lead to the formation of uniform requirements for such accounting objects as "cross-industry processes", "regulatory sandbox", "digital platform", "digital transformation", "digital ecosystem", "digital conversion", "digital asset". In Fig. 1, we present a graphical model of the temporal features of the accounting paradigm in the digital economy.

Along with defining the contours of international legal regulation of digitalization processes under the aegis of the EAEU, the Union's members independently develop, form and implement national policies in the field of digitalization of the economy, including the implementation of national measures to develop the digital agenda.

The increasing speed of iterations that change further development of human anthropology in the context of the development of digital transformation of the economy and, above all, its information and legal part, will inevitably affect the general paradigm of accounting. Accounting methods, including its basis—double-entry bookkeeping, reporting forms, structure of accounting registers, qualitative parameters of reflection of some facts of economic life, principles, concepts of formation of accounting policy of subjects of economic activity will be subject to certain transformation. Against the background of changes in the forms of access, orderliness and structuring of information support and thinking, in the modern economy, the actual scientific problem of perspectives of development of accounting paradigm in conditions of growth of digital transformations, interstate integration processes of the Eurasian Economic Union, determination of the content of the term 'temporal features' is formed.

Table 1 Content and structure of temporal development features of the digital economy

Title	Content	Structure
Digital specifics	Digital specifics require compromises between empowering users and protecting their freedoms	Inclusive design Digital identification Citizen participation Banks and capital markets Financial and currency systems Blockchain Flexible management Internet government
Data sharing and permissions	Unprecedented volumes of data require greater clarity in terms of confidentiality, rights and authorizations. Data provides important information, and we are witnessing a revolution in the way this information is collected, managed and shared	Information technology; International trade and investment Health and healthcare Personalized medicine Human rights Internet interaction of things
Security of people and processes	The growing amount of information represents an increased risk, requiring a comprehensive defence strategy. Cyber threats challenge our ability to take full advantage of the digital economy	Artificial intelligence and robotization Internet control Corporate governance The fourth industrial revolution Global risks Cyber security
Informed, flexible management	The global nature of digital communications requires a flexible and informed regulatory framework. The institutions that have traditionally been responsible for shaping the social impact of new technologies are struggling to keep pace. At the same time, there is a sharp decline in public trust worldwide, especially in key public, social and societal institutions	Flexible management Information technology International trade and investment Artificial Intelligence and robotization The fourth industrial revolution Global management
Stability of digital transformation	A new leadership approach is needed to create a sustainable digital business In every industry, digital transformation is pushing companies to re-evaluate their business models, and new market players focused on technological innovation are transforming the strategic landscape	Virtual and augmented reality Entrepreneurship Blockchain Innovation The future of economic progress Leadership in the fourth industrial revolution 3D printing

(continued)

Table 1 (continued)

Title	Content	Structure
Access and implementation	Half a century after the invention of the Internet, only half the world is connected to the Internet. While the pace of technological development, adoption and transformation is accelerating for many people, the world is still far from achieving universal access to Internet services. According to the International Telecommunication Union, at the end of 2018, just over half of the world's population—51.2%—was using the Internet	Digital communication Sustainable development 5G Education and skills Infrastructure Corruption Gender equality Behavioural sciences

4 Conclusion

Thus, the substantiation of scientific approaches in the solution of the above-defined problem is relevant both in the search for solutions that depend on the speed, dynamics of changes in endogenous factors, the regulatory framework of the corresponding regulator, and the interoperability of sections of the developed accounting policy of the subjects of economic activity.

Temporal features of the paradigm of accounting in the digital economy is an interoperable system of temporary (transitional) principles, approaches and priorities related to economic, legal and informational and technical relations of the implementation of accounting, which are recursively changed under the influence of the development of digital economy, and directed to the development of economic agent's environment, with a digital way of regulation and institutionalization of processes.

In the proposed field of scientific rhetoric of the iterative approach to the development of the Concept, there is a shred of forming an integral core of research to further disclose such scientific tasks as:

- defining the economic and legal framework for government regulation of accounting based on the use of big data, cloud computing at the stages of monitoring, goal setting, decision making, and evaluation of management results;
- creation of principles for building accounting policies aimed at improving the effectiveness of the digital communications system, digital literacy of economic entities in connection with the development of digital technologies;
- formation of conceptual and categorical objects favourably influencing information and technical conditions of stimulation of development and introduction of new digital technologies in the process of competitive interaction, and creation of information platforms for interested subjects of economic activity.

Management of Scientific and Technological Competitive Advantages in the National Industry

Olesya I. Dontsova, Niyaz M. Abdikeev, Yuriy S. Bogachev, and Segey A. Tolkachev

Abstract *Purpose*: The article is devoted to the adjustment of managerial tools to ensure a technological breakthrough in the Russian economy with the help of scientific and technological developments. *Design/methodology/approach*: The methodological background of the study is the theoretical principles of systemic, factor, functional, logical, comparative, and statistical analysis. These methods made it possible to assess the performance of state policy in the scientific and technological field relying on the findings of the corresponding analysis. A factor analysis of the mechanisms for the transformation of scientific developments into technologies has revealed problems in the structure of these mechanisms. *Findings*: The article has shown the low performance of funding some priority areas of scientific and technological development and the high sparseness of the innovation cycle in several sectors related to scientific and technological development. Thus, the academic sector takes a leading position in scientific research but makes a small contribution to the patents. The companies that lay scientific and technological groundwork almost don't cooperate with institutions that introduce technological solutions into practice. Therefore, innovation performance is low. Over the past 5 years, there haven't been considerable shifts in the technological development of Russia. The country lacks an integrated approach to the focus of scientific potential on high-tech innovations. The authors suggested the structure of a scientific and technological platform for the generation of knowledge and its transformation into competitive technologies in prioritized sectors of the real economy. *Uniqueness/value*: The findings can be useful in solving the strategic tasks on the upgrade of high-tech processing industries.

1 Introduction

In the modern economy, the processing industry is the main driving force of sustainable economic growth. The transformation of the processing industry towards its complication (augmentation of added value) leads to structural changes in the economy that will provide for economic growth [1].

The studies of the United Nations Industrial Development Organization (UNIDO) have revealed a correlation between the complexity of process manufacturing and the income of a country's population, calculated as per capita GDP by purchasing power parity (PPP).

The growth of per capita income is accompanied by a decreasing share of low-tech industries (in the UNIDO classification) and a greater share of mid- and high-tech industries. Besides, one risky pattern has been discovered, i.e. if the share of high-tech industries does not grow in the structure of the economy under $15–20 thousand per capita income, then the likelihood of the country's income decline increases. This condition can be to some extent described as a "middle-income trap" [2].

Thus, the transformation of Russia's processing industry structure towards a higher share of high-tech industries is deemed as a crucial factor in providing sustainable economic growth.

2 Methodology

One of the national goals of the Russian Federation underlying the country's modern economic policy is to step up the technological development of Russia, increase the number of technologically innovative companies with a share of at least 50% of the total figure. Simultaneously, among the guidelines for national economic development is the establishment of a high-tech export-oriented sector in the processing industry [3].

The basic means of achieving national goals is a system of twelve national projects.

The problem of choosing priority sectors for the development of the national economy is complicated and multi-sided. For the technological projection of future growth points of the economy, the Delphi and Forsyth methods are widely used (the latter prevails in later studies).

The standard projection algorithm for technological growth points includes:

- Investigating global trends in technological development;
- Setting strategic goals;

- Simulating scenarios of setting scientific and technological priorities [4].

The current financing scope of basic and applied research from the federal budget has been declining since 2013.

Along with that, the volume of domestic costs for research and development has been average since 2000 (1.11% of GDP). The standard deviation is 0.08%, the median value is 1.1%.

In the financing structure of research, priority is given to ones aimed at the development of real sectors of the economy. Also, there is a direction of general scientific development.

In the financing structure research and development on the provision of sustainable growth of the Russian economy, industrial production is prevailing. The growth of R&D costs' share in industrial production against the costs for domestic research aimed at supporting the economic development rose from 68.8% in 2010 to 76.7% in 2017 (see Table 1).

To date, priority areas for scientific and technological development are enshrined at the government level. Breakthrough in these fields is designed to provide the Russian economy with sustainable competitive advantages in the long term [5].

Over the past five years, there has been a positive trend in financing priority areas for the development of science and technology. The funding scope is rising mainly

Table 1 The pattern of domestic research costs in the context of the socio-economic goal "economic development"

	2010 (%)	2011 (%)	2012 (%)	2013 (%)	2014 (%)	2015 (%)	2016 (%)	2017 (%)
Economic development	100.00	100.00	100.00	100.00	100.00	100.00	100.00	100.00

due to budgetary allocations, the business sector doesn't make a weighty contribution (see Fig. 1).

More than a third part of funds over 2013–2017 has been spent on "transportation and space systems". The next capital-intensive areas are the energy power industry and information and telecommunication systems (Table 2).

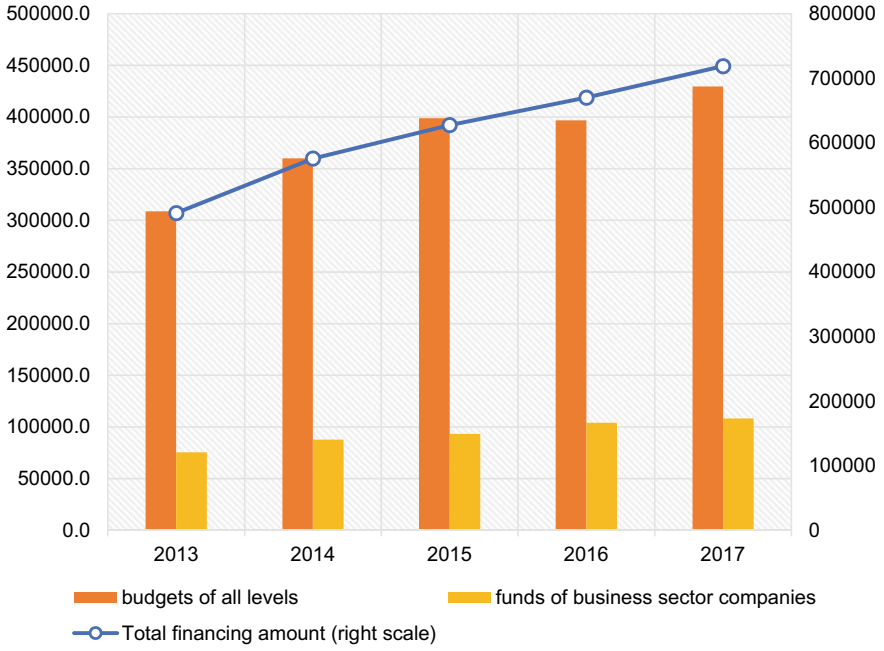

Fig. 1 Dynamic trend of funding priority areas for scientific development. *Source* Compiled by the authors on the back of works by Gorodnikova et al. [10]

Table 2 The financing pattern of major areas of scientific and technological development

Scientific development areas	2013 (%)	2014 (%)	2015 (%)	2016 (%)	2017 (%)
Information and telecommunication systems	12.22	12.27	11.88	11.63	11.32
NANOSYSTEM industry	3.81	4.23	4.05	3.87	3.11
Biosciences	5.98	6.24	6.98	7.27	7.20
Efficient use of natural resources	6.78	7.09	7.40	7.72	7.75

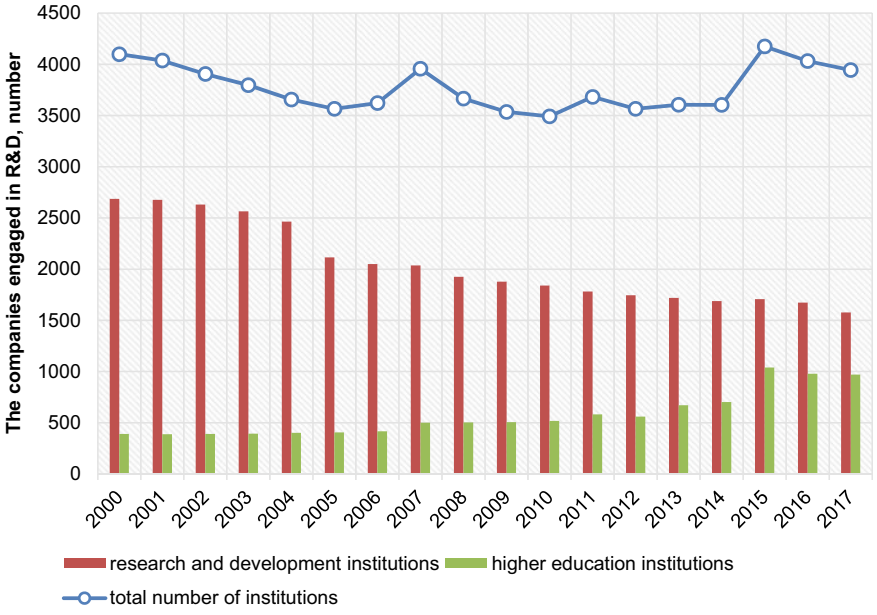

Fig. 2 The dynamic trend of institutions' engagement into research and development. *Source* Compiled by the authors on the back of works by Gorodnikova et al. [10]

Research institutes are the first among research and development institutions but their share in the total volume is steadily decreasing. At the same time, the involvement of higher education institutions in R&D is growing (see Fig. 2).

Transportation and space systems ate the most heavily-invested. Eighty-three intellectual property items have been created in this area. According to experts from the Ministry of Industry and Trade, three intellectual property items (i.e. 3% of the total number of intellectual property items) are evaluated as world-class items.

As for the nanosystem industry, four intellectual property items have been created (4% of the total number of intellectual property items), one of which is recognized as world-class.

Eight intellectual property items have created in the field of information and telecommunication systems, two of which (2% from the total number of intellectual property items) are world-class.

In the direction "energy efficiency, energy conservation, nuclear power industry", five items of intellectual property (or 5% from the total number) have been created.

Thus, the companies of the Ministry of Industry and Trade have created 6 world-class items (6% from the total number).

Over the 2017–2018 Rospatent of the Russian Federation have recognized as the best 200 patents created in the Russian Federation.

Institutions of the state academies of sciences participate in research and development (under the federal targeted program, the domestic targeted program, and state

assignment) to increase the competitiveness of the high-tech sectors of the domestic economy [5].

The highest number (75 of the best patents) is presented in the fields of chemical (organic and inorganic) compounds, biochemistry and medicine. In the context of priority areas for scientific and technological development, the best possible number of patents accrue to "biosciences" and "nanosystem industry". It is worth noting that areas have been funded far inferior to need (3.1% for the nanosystem industry and 7.2% for the biosciences).

The greatest funds have been allocated to "transportation and space systems" (33–37% in recent years), but this area hasn't brought scientific findings as either intellectual property or the best-recognized patents. It is tempting to suggest that R&D in the field of space technology (no need to count transportation ones) have never been intended, and Russian cosmonauts are exploited as cabs for "representatives of civilized nations" until a new generation of American shuttles comes into operation.

As for institutions engaged in research and development, the highest number of the best patents in 2017–2018 belongs to private companies and higher education institutions, while the ones of the academy of sciences and field-specific research institutes (as ones engaged in R&D to the fullest extent) were lagging far by the number of the best patents (Table 3).

It should be noted that the professional status of domestic scientists is quite high in the world. The number of publications by authors indexed in Scopus and Web of Science is stable (nearly 2.5–3.0% of the worldwide refereed publications) (Fig. 3).

According to the Web of Science, Russian works in the field of natural sciences (61.2% of refereed publications) and engineering and industrial technology sciences (32.5% of refereed publications) are the most cited. These figures are comparable with global trends in a particular way. The publication activity in the field of medical sciences in our country is much inferior to the global average indicator (Table 4).

Scientists working in Russian higher education institutions are highly appreciated in the West. However, by the amount of state-allocated funds for the development of this high-potential direction, this one is in third place from the bottom of the list.

Table 3 Distribution of the best patents among the institutions engaged in research and development

Type of institution	2017	2018
Institutions of the Russian Academy of Sciences	9	10
Higher education institutions	17	39
Private companies	43	23
Research institutes	11	11
Defense industry enterprises and state corporations	3	13
Individuals	17	4
The total number of the best patents	100	100

Source Compiled by the authors on the back of data from the Rospatent official website [11]

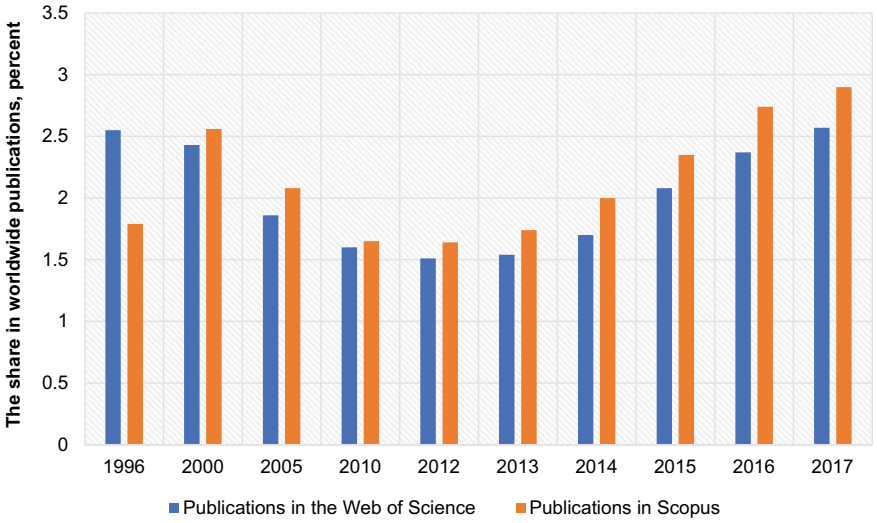

Fig. 3 Dynamic trend of the share of Russian authors in foreign publications. *Source* Compiled by the authors on the back of works by Gorodnikova et al. [10]

Table 4 The proportion of publications in 2017 by science domain

Science domain	Russia	World
Natural and exact sciences	61.2	46.1
Engineering and industrial technology sciences	32.5	30.4
Social sciences	11.3	13.3
Medical sciences	6.9	26.1
Human sciences	6	4.8
Agricultural sciences	0.8	3.9

Source Compiled by the authors on the back of work by Gorodnikova et al. [10]

Therefore, we can rightfully assume that Russian scientists engaged in the development of information and telecommunication technologies are underestimated at home.

Under the subject heading list at the Web of Science, the most demanded areas of our higher-education science abroad are physical sciences, mathematical sciences, engineering, and mechanical engineering, chemical sciences, materials science. In the field of physical and historical sciences, Russia ranks fourth in the world by the number of publications, in mathematics—the fifth. The top ten areas for publications comprise chemical sciences, materials science, engineering, and mechanical engineering.

An important component in creating competitive advantages is the marketing of R&D progress. The Russian economy has deep gaps in this direction.

A critical problem of the Russian processing industry today is the lack of technological groundwork in most industrial sectors, as well as insufficient use of current relative advantages.

The current strategy for the technological development of Russian enterprises is based on the adoption of advanced foreign technologies. The Russian imports are dominated by high-tech process manufacturing products (machinery and equipment—30%, vehicles—14%, high-tech chemical products—12%).

The share of imported equipment in the sectors that are key for Russia (energy power industry, metallurgy, chemical industry) has reached a critical level.

To discover the most competitive non-resource sectors of Russian industry, we have conducted an analysis of the international OEC database of the Massachusetts Institute of Technology (The official website of Rospatent and data from the Stockholm Institute for World Studies).

In 2017, the proportion of high-tech products in Russian export was considerable (machinery and equipment—3.6%, vehicles—2.3%, products of the defense-industry complex—0.07%) [6].

Over 2017, the export of machine engineering has amounted to $12.4 billion (25% accrued to gas turbine aircraft engines and equipment for nuclear reactors).

The exports of transport engineering products in 2017 amounted to 7.7 billion US dollars (aircraft products accounted for 24%) [7].

3 Findings

The analysis presented by us showed that the country lacks a system of focusing scientific potential on high-tech innovations that would contribute to the technology-savvy development of the Russian economy.

The economic science has demonstrated that the high-tech sector of process manufacturing is the main driver of sustainable socio-economic development in the context of the transition to the sixth technological paradigm [2, 4, 8].

4 Conclusions/Recommendations

In Russia, there are scientific developments that can underlie competitive advantages in the basic industries of the new technological paradigm. In his work Bogachev [9] describes how to use these developments in the chain of scientific developments—technology—production—marketing. To ensure the performance of this chain for each high-tech industry, it is necessary:

- to develop a system for selection of research group having internationally recognized and promising developments for high-tech innovations that meet the requirements of the sixth technological paradigm;

- after negotiation of selected research groups, to work out a package of product and process innovation projects, which introduction into economic activity will create cost-effective production chains of competitive product innovations;
- to design an organizational platform for the accomplishment of these projects that would operate on network principles;
- to elaborate regulatory provisions for the establishment and performance of the Council that would coordinate the projects through scientists having experience in development and introduction of intellectual property items, design engineers, engineers, product designers, managers of companies that are competitive in the global market, as well as senior officials of Presidential Administration and deputy prime ministers administering relevant areas of industry.
- to set up a mechanism of redistributing state support in favor of scientific sectors that possess high potential for the creation of scientific and technological competitive advantages.
- to develop a system of state orders for basic research at the Academy of Sciences and leading research and educational centers of Russia.
- to pursue the policy of international scientific cooperation in academic and higher education cooperation, engage the international scientific community into the execution of joint projects at Mega science units being constructed within the framework of the national project "Science".

Acknowledgements The article has been written on the back of findings of state-funded research conducted on the state assignment to the Financial University.

Attitude of the Russian Population towards the Processes of Digitalization of the Economy and Provision of Public Services

Elena Z. Imaeva, Julia V. Kostikova, and Natalia A. Sukhareva

Abstract The aim is to study the attitude of the Russian population to the processes of digitalization of the economy and provision of public services. This article will present the results of the study of the attitude of the Russian population to the processes of digitalization of the economy and provision of public services. The article contains the data of the survey of 250 respondents aged from 40 to 60 years. The survey was conducted in September–December 2019. As a result of the survey using cluster analysis, three groups of respondents were identified: the first group (72 people) included "passive" buyers of products and services in online stores, who are afraid of fraud and deception when buying; they usually spend from 1 to 3 thousand rubles on purchases, rarely making purchases online. They also refuse to use the Common Government Services Portal for fear of passing on their personal data to third parties. The second group of "confident" consumers (91 people) includes respondents who make purchases 1–2 times a month. They most often buy tickets and goods at lower prices and stocks, and are afraid of making insecure payments. Reducing time costs for them is the main reason for using the Common Government Services Portal. The third group of "cautious" consumers (87 people) consists of people who usually make online purchases of tickets and other goods 1–2 times a month, seeking to buy goods at lower prices and stocks and spending on them from 3 to 5 thousand rubles per month. They often use the Common Government Services Portal, as its advantage for them is the absence of queues. Thus, the study shows the features of consumer behavior of respondents over 40 years of age when making online purchases and using public services.

Keywords Digital economy · Consumers · Online shopping · Online stores · The common government services portal

JEL Classification D78 · O10 · O35

1 Introduction

Nowadays, more and more consumers use the services of Internet shops, purchase goods on the Internet, apply to portals of state and municipal services. The development of digital technologies and the digital economy makes it important to study not only new technical innovations, but also the specific behavior of consumers of these services. And if young people treat the digitalization of our surrounding lives as something they are used to, the older generation continues to be distrustful of the new digital opportunities. The purpose of this research is to study the attitude of the Russian population to the processes of digitalization of the economy and provision of public services.

2 Methodology

Recently, the issues of consumers' evaluation of the processes of digitalization of the economy and provision of public services have become the subject of research by a number of authors. Most of the works are devoted to describing the Internet audience of buyers and studying consumer behavior in online shopping [1–9] and etc.

The other part of the works reveals the peculiarities of receiving public services online [10–15] and etc.

At the same time, it should be noted that this topic continues to be of interest to researchers, first of all, in the analysis of the peculiarities of consumer behavior depending on their sex, age, social status, etc.

This article will present the results of the study of the Russian population's attitude to the processes of digitalization of the economy and provision of public services. As part of the study, 250 respondents aged 40 to 60 years were surveyed. The study was attended by 147 women and 103 men. The survey was conducted in September–December 2019. The survey questionnaire that we developed included 10 questions.

3 Results

As the answers to the question "Do you often shop online ordering goods or services?" showed, most respondents make such purchases frequently, at least once a week (58

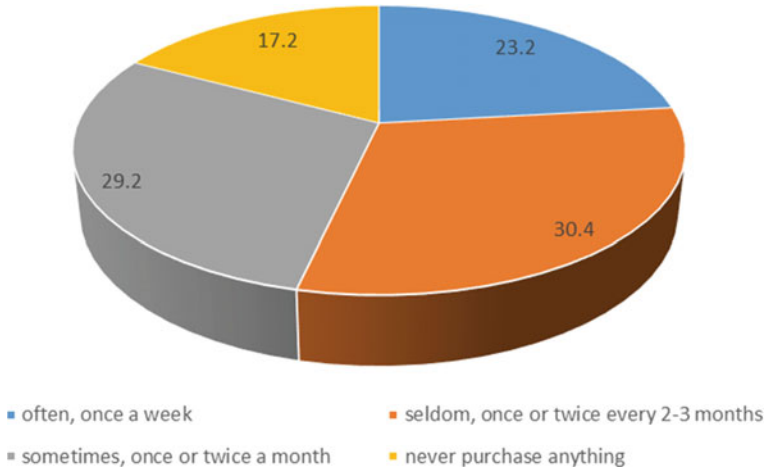

Fig. 1 Answers to the question "Do you often shop online when ordering goods or services?"

people—23.2%) or sometimes, 1–2 times a month (73 people—29.2%). Rarely, 76 respondents (30.4%) make such purchases 1–2 times a month. No online purchases are made by 43 respondents (17.2%)—Fig. 1.

When asked which goods and services you purchase online most often, the answers were distributed as follows: tickets (cinema, theatre, railway and air tickets) (112 respondents—44.8%); phones and accessories (31 people—12.4%); clothes and footwear (20 people—8%); food (11 people—4.4%); goods for children, goods for repair and educational services (9 people—3.6%); medicines and goods in the category "Beauty and Health" (8 people—3.2%). 41 respondents said that they do not buy goods online (16.4%)—Fig. 2.

When asked what are the main advantages of buying goods and services online, respondents noted such options as reducing the time for shopping (58 people—23.2%); the ability to deliver goods home (37 people—14.8%), buying goods around the clock (41 people—16.4%), buying goods at lower prices, promotions and a wide range of products (20 respondents—8%); buying exclusive and unavailable goods or services (39 people—15.6%); delivery of goods home (35 people—14%)—Fig. 3.

The drawbacks of online purchases of goods and services include: insecure payments; poor quality of goods, their inconsistency with the stated characteristics in the description (by 56 respondents—22.4%); duration of delivery of goods (44 people—17.6%); high probability of fraud and deceit (42 respondents—16.8%); lack of opportunity to "feel" the goods (32 people—12.8%) and the risk of damage to the goods during delivery (20 people—8%) (Fig. 4).

Most often, consumers spend from 1 to 3 thousand rubles per month on purchases (156 people—62.4%). Less than 1 thousand rubles is spent by 34 people (13.6%). 17 respondents (6.8%) spend on shopping from 3 to 5 thousand rubles. No purchases are made by 43 respondents (17.2%)—Fig. 5.

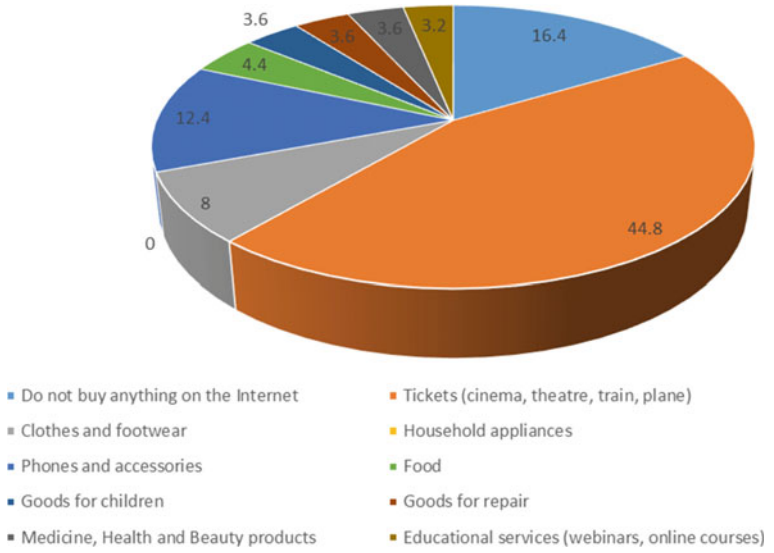

Fig. 2 Answers to the question "What kind of goods and services do you most often buy online?"

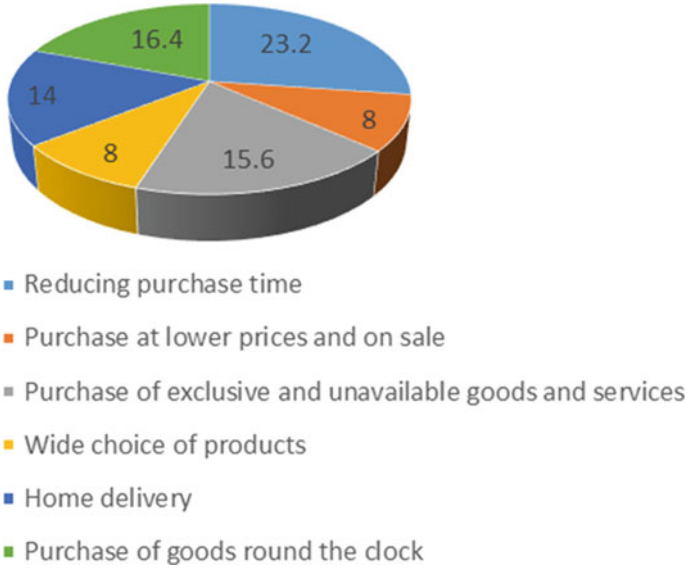

Fig. 3 Answers to the question "What do you think are the main advantages of buying goods and services online?"

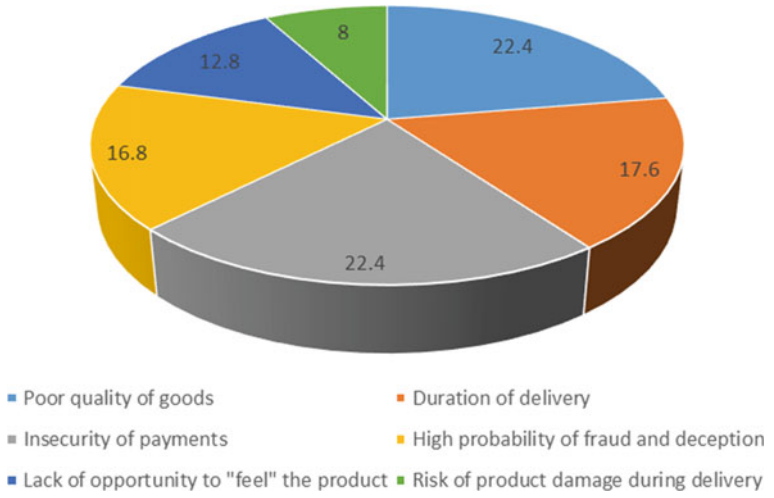

Fig. 4 Answers to the question "What do you think are the main disadvantages of buying goods and services online?"

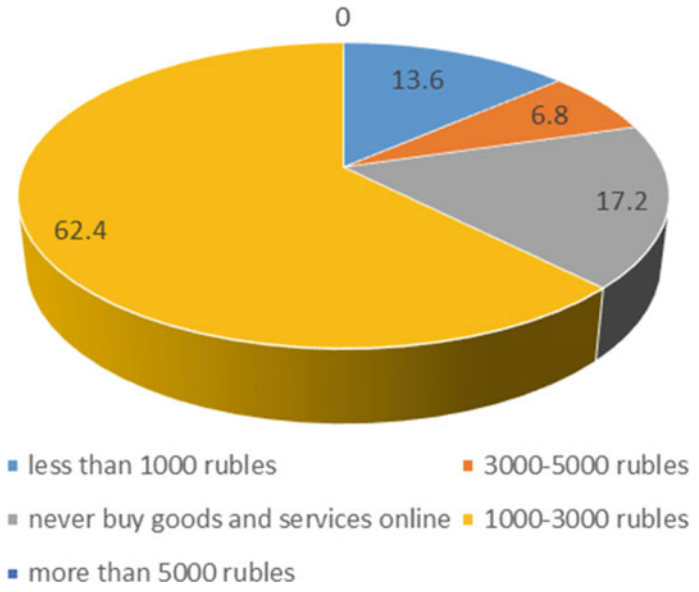

Fig. 5 Answers to the question "How much do you usually spend on online shopping per month?"

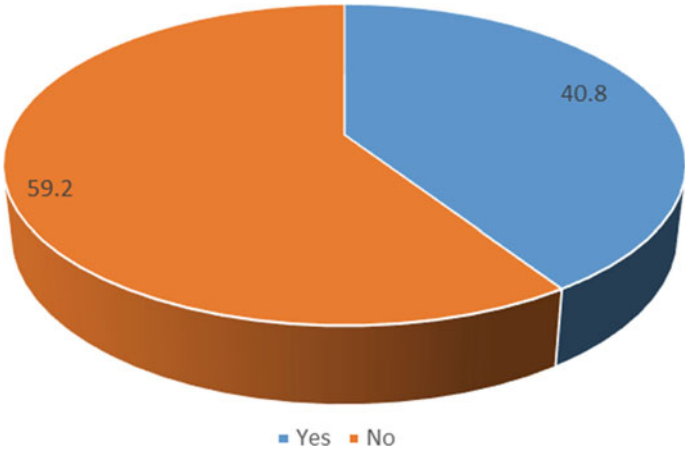

Fig. 6 Answers to the question "In your opinion, will you make more purchases online in the future?"

When asked whether you will make more online purchases in the future, 102 respondents (40.8%) answered in the affirmative, and 148 people (59.2%) answered in the negative—Fig. 6.

The next group of questions was devoted to the study of respondents' attitude towards the possibilities of using the Common Government Services Portal.

Answering the question of whether respondents use the services of the Common Government Services Portal, 178 people (71.2%) answered in the affirmative, and 72 respondents (28.8%)—in the negative—Fig. 7.

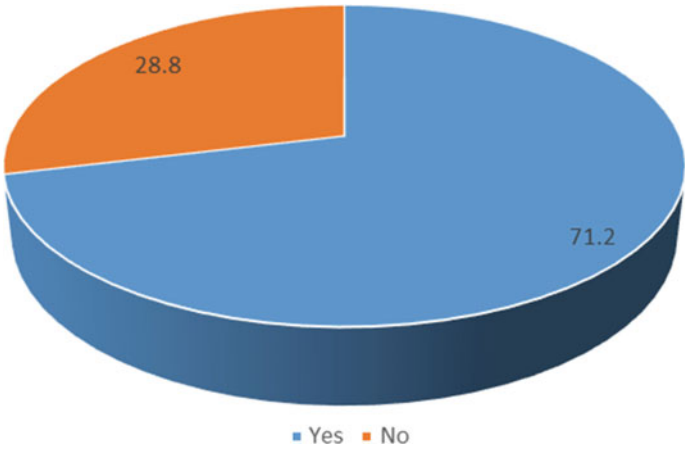

Fig. 7 Answers to the question "Do you use the Common Government Services Portal?"

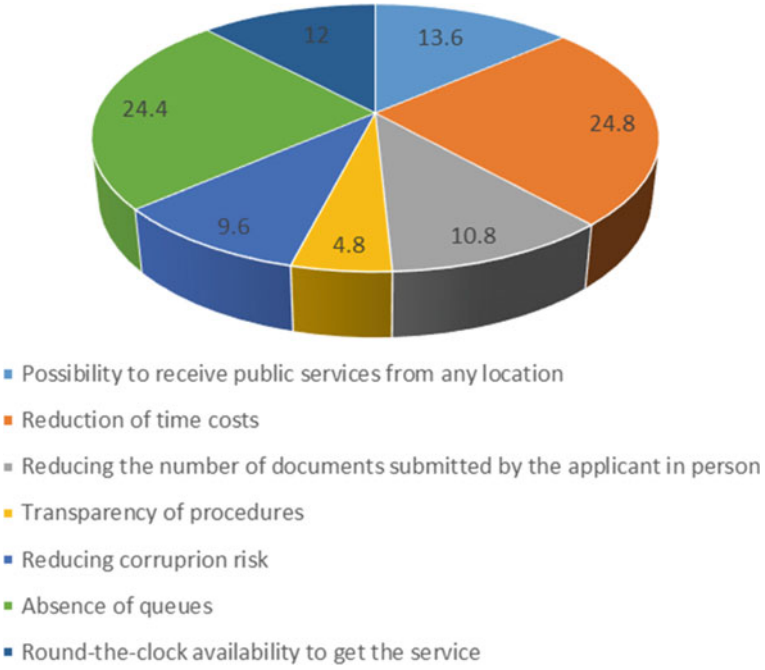

Fig. 8 Answers to the question "What do you think are the main advantages of receiving public services online?"

The main advantages of obtaining public services online were: the possibility of obtaining public service from any location (34 people—13.6%); reduced time costs (62 people—24.8%); reduced number of documents provided by the applicant in person (27 people—10.8%); transparency of the procedure (12 respondents—4.8%); reduced corruption risks (24 people—9.6%); no queues (61 respondents—24.4%); round-the-clock availability of services (30 respondents—12%)—Fig. 8.

The following reasons were mentioned by the respondents as disadvantages of receiving public services online: not all public services are available online (45 people—18%); possible technical errors in the work of the portal (58 respondents—23.2%); the danger of open access to personal data (42 people—16.8%); low information content of sites (27 respondents—10.8%); difficulties in self-registration on the site and finding the necessary information (78 people—31.2%)—Fig. 9.

Finally, 164 respondents (65.6%) answered affirmatively to the last question of the questionnaire "Do you think you will use the Common Government Services Portal more in the future?" Finally, 164 respondents (65.6%) answered affirmatively to the last question of the questionnaire "Do you think you will use the portal of public services more in the future?", while 86 people (34.4%) answered negatively to Fig. 10, while 86 people (34.4%) answered negatively to Fig. 10.

Further data processing was performed using cluster analysis (*K*-average)—Fig. 11.

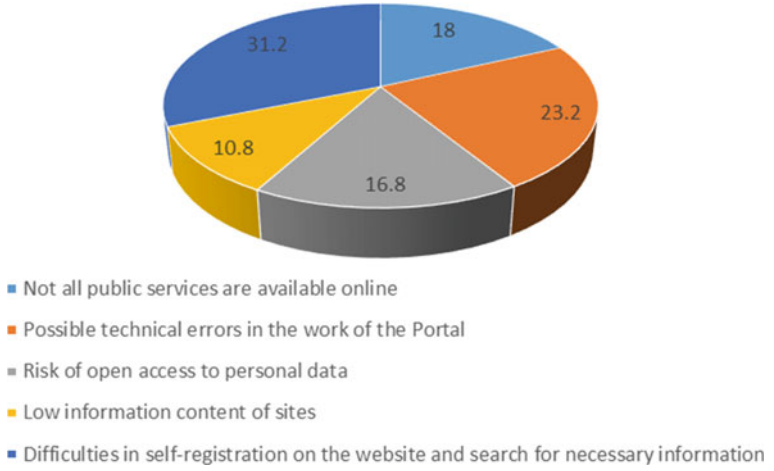

Fig. 9 Answers to the question "What do you think are the main disadvantages of receiving public services online?"

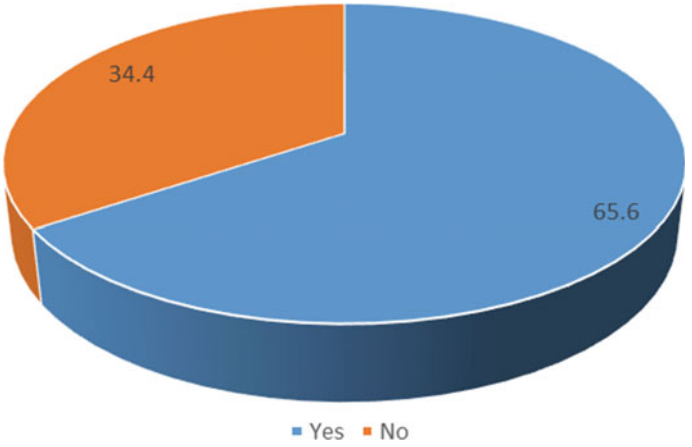

Fig. 10 Answers to the question "Do you think you will use the Common Government Services Portal more in the future?"

The cluster analysis allowed identifying three main consumer groups.

The first "passive" group of buyers (72 people) are respondents who rarely shop online, most often buying phones and accessories. They buy goods at lower prices and on sale promotions, are afraid of fraud and deception when buying, and usually spend from 1 to 3 thousand rubles on goods and services. Respondents in this group do not plan to make more online sales in the future. They are also characterized by a refusal to use the Common Government Services Portal. They highlight the transparency of the procedure as an advantage, and the risk of public access to personal data as

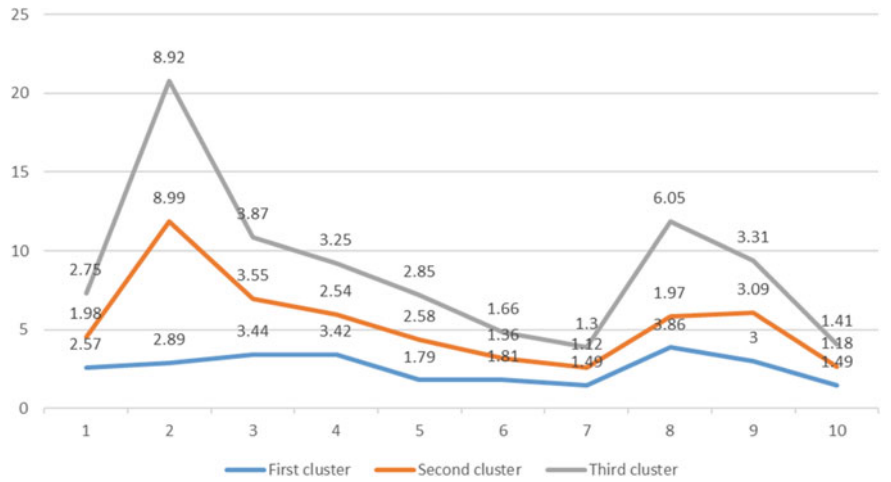

Fig. 11 Cluster analysis results of *K*-average

a disadvantage. They do not plan to use the Common Government Services Portal anymore in the future. In general, they are concerned about new digital opportunities when purchasing products or using public services online.

The second group of "confident" consumers (91 people) make purchases 1–2 times a month, most often buying tickets and goods at lower prices and stocks. As a drawback of online purchases, they point to the insecurity of payments. Usually this group of buyers spends from 1 to 3 thousand rubles on purchases at online stores. In the future, they plan to make more purchases. They also use the services of the portal of public services, the advantage of which is the reduction of time spent, while the disadvantage is the danger of open access to personal data. In the future, they also plan to use the portal services more often.

The third group of "cautious" consumers (87 people) consists of respondents who use online shopping 1–2 times a month, usually buying tickets and trying to buy goods at lower prices and on sale. They are willing to spend from 3 to 5 thousand rubles a month on purchases. As a drawback of online purchases are called insecurity of payments. In the future, they plan to make purchases online more often. They also often use the services of the portal of public services, with the absence of queues as its advantages. Representatives of this group fear open access to personal data, but plan to use the public services portal more in the future.

4 Conclusion

Respondents over 40 years of age took part in our survey. As a result of our work, three groups of respondents were singled out, to whom we gave notional names

of "passive", "confident" and "cautious" consumers. Thus, the work showed the specifics of the behavior of these three groups of respondents when making online purchases and using public services.

The life of a modern person is inextricably linked with digital culture. The understanding of "informatization" is connected with the archaeological method of Foucault and the central problems of knowledge/power. At the same time, the priority of the social machine over the technical one is always traced in digital culture. This is because technology can't develop without universal exchange and self-regulation. Digitalization processes are directly dependent on consumer behavior.

Digitization of the Process of Administrative-Legal Declaration of Compliance with Mandatory Requirements by Supervised Entities as Part of an Automated Risk Management System

Anatoliy V. Zubach, Gleb N. Vasilenko, and Elena E. Tomilina

Abstract The paper supports the author's viewpoint on administrative and legal nature of the declaration institution, as exemplified by the declaration of compliance with the statutory requirements by the supervision entities in the field of transportation. The potential for the digitization of declaratory administrative procedures in this field is regarded as a demonstration of the positive trends in the development of this method of public administration.

Keywords Institution · Administrative law · Declaration process · Management · Efficiency · Declaration · Supervision · Monitoring · Digitization

In the context of the intensive development of digital information technologies, branches of law are gradually being enriched by appropriate mechanisms for regulation of relations in a wide variety of areas of society. Administrative law is no exception, but, on the contrary, has established itself as a leading choice in the perception of changes in a digital information environment. "The Regulatory Guillotine", the transformation of administrative-tort legislation, the development of the institution of public services—these fundamental processes are inextricably intertwined with the digitization of management processes, which makes it possible to accelerate the implementation of mandatory norms.

The legal administrative declaration institution, being a relatively new legal entity, is characterized by the peculiarities of the legal regulation method, which, while

preserving its mandatory nature, relies primarily on such elements of administrative-legal regulation as legal culture and legal awareness. The notification nature of the declaration method, whereby the authorized executive authorities (declaratory bodies) exercise their powers through remote interaction with declarants, when receiving information about the controlled entities directly from the declarant during the declaration process, automatically trust such information, preserving their legal competence to monitor compliance with the conditions of the declaration process [1–4].

All types and stages of declaratory control are regulated with the utmost precision in administrative law. It is the preliminary declaration control and ongoing declaration control that primarily require digital enforcement, including for anti-corruption purposes.

At the stage of preliminary declaratory control, the declarant independently collects information about the controlled object and submits it to the declaratory body of executive power in accordance with established rules. In addition, at the stage of ongoing declaration control, the declarant makes timely relevant changes to the declared characteristics of the object of declaratory control in the appropriate forms by notice.

The executive branch, legally represented by declaratory bodies, only monitors, in the framework of scheduled and unscheduled inspections, the compliance of declared information with the actual state of the controlled entity. It should be clarified here that declared objects are numerous and varied, and their number is increasing every year, thus filling the regulatory framework of the relevant administrative-legal institution. The established sub-institutions of administrative-legal declaration have their own facilities: energy declaration, tax declaration, customs declaration, fire declaration, declaration of conformity of quality of various types of products, industrial declaration, declaration in forestry, anti-corruption declaration, investment declaration and environmental declaration, declaration of bank assets and accounts (deposits) and many others.

The digitization of the process of declaration of compliance of supervised entities with the established requirements of Rostransnadzor is of interest within the scope of declared topic. The pilot project developed by the abovementioned office reveals far-reaching possibilities for similar modernization of enforcement mechanisms and other sub-institutions of administrative-legal declaration.

As part of the project, plans call for organization of an automated system that will enable the declaratory body (Rostransnadzor) to indirectly, bypassing interaction with declarants (supervised entities), carry out continuous monitoring of compliance with mandatory requirements of relevant Russian legislation by these entities, as well as to study the prospects for introducing a new type of supervisory activity—continuous monitoring; which provides for rejection of scheduled inspections of supervised entities in certain fields of transportation.

For the purpose of continuous monitoring, a special agreement on information exchange is concluded between the federal supervision agency in the field of transportation and the entities under its supervision, according to which a supervised entity

sends information on the fulfilment of mandatory requirements for the respective activities.

Self-declaration is carried out digitally in the Unified Computerized Database of the relevant supervision agency by sending the results of the self-assessment of compliance with mandatory requirements to the automated risk management system of the abovementioned agency.

Self-declaration is preceded by the self-assessment of compliance with mandatory requirements by the supervised entity. In turn, the self-assessment service consists of two modules: self-assessment test and self-assessment followed by the declaration process.

The test self-assessment module can be found on the official information resource of the supervision agency in the field of transportation http://rostransnadzor.ru and is used for the self-assessment by the supervised entity of the fulfilment of relevant requirements related thereto, in order to identify gaps and take independent action to address them.

During the test self-assessment, startup information on the supervised entity is kept confidential, and data on the results of the self-assessment are not delivered to the unified information analysis system of Rostransnadzor. A self-assessment test is required to prepare for the self-assessment in the personal cabinet of the supervised entity, followed by the process of declaration of compliance.

The service of self-assessment followed by the declaration process is similar to the self-assessment test service, is located in the personal cabinet of the supervised entity and is intended for self-assessment by the identified supervised entity of the fulfilment of supervisory requirements, followed by sending of results of the self-assessment to the automated risk management system of the supervision agency and the process of declaration of compliance with mandatory requirements. Sending of the declaration to the supervision agency's risk management system indicates that the supervised entity has complied with mandatory requirements applicable to its activities and that the supervised entity has taken necessary measures to ensure the security of its transportation facilities and means. The process of declaration of compliance with mandatory requirements can only be implemented if the results of the self-assessment in the personal cabinet are positive.

The systematic nature of self-declaration may be determined with due consideration for the fact that the activities of the supervisory body are classified as one of the categories of risk: high, significant, medium or low. In the event that violations or indications of breaches of mandatory requirements are detected in the supervised entity during the continuous monitoring, such entity is duly warned against the violation of mandatory requirements.

Failure by the supervised entity to take measures to eliminate the signs of violation of mandatory requirements which are defined by the declaratory body as risk indicators in accordance with the relevant law, is the basis for an unscheduled inspection.

The abovementioned mechanism of enforcement of compliance with mandatory requirements of the sub-institution of administrative-legal declaration by the entities under its supervision allows:

- reducing the risks of corruption arising during inspections;
- reducing the bureaucratic load on business sector, replacing field inspections by remote interaction with supervised entities;
- establishing a system for early detection of violations of supervision requirements that may have negative consequences that threaten public security and the rule of law.

Digitalization and Application of Telemedicine Technologies in Healthcare of the Russian Federation: Economic and Legal Aspects

Farit N. Kadyrov, Abdula M. Chililov, Irina V. Shutikhina, Bagavdin G. Akhmedov, and Valery V. Antonov

Abstract *Purpose*: The purpose of this research is to analyze the legal and economic limitations of the telemedicine technologies that are typical for most countries, and to develop approaches based on the experience of the Russian Federation to overcome them. *Design/Methodology/Approach*: The authors consider the system of legal and economic relations that arise between different participants in the provision of telemedicine services, focusing on international experience in this field. The economic problems of using telemedicine technologies are evaluated by analyzing the economic interests of each of these participants. At the same time, the main focus has done on determining the ratio of additional costs and additional benefits for each of the participants associated with the provision of telemedicine services. *Findings*: on the example of the Russian Federation, the analysis of legal and economic restrictions for the development of telemedicine technologies, characteristic of many countries, is carried out. A number of common problems of implementing telemedicine technologies have been identified, as well as specifics of them in the Russian Federation. Methods of economic incentives for providing telemedicine services in the framework of the compulsory health insurance system are analyzed. *Originality/Value*: the measures aimed at overcoming a number of legal restrictions in the use of telemedicine services related to licensing, the degree of legal responsibility

of doctors, etc. are proposed. Methodological approaches to the classification and measurement of costs of various parties involved in the provision of telemedicine services, which must be taken into account when evaluating the effectiveness of telemedicine technologies are justified. At the same time, it is proposed to allocate two main groups of costs for the introduction of telemedicine technologies: (1) necessary costs and (2) investments. The differences between these concepts are described in relation to the sphere under consideration.

1 Introduction

In recent years, there has been a rapid development of telemedicine technologies all over the world. However, at the same time, more and more problems that arise in this regard are being voiced. At the same time, the technological aspects of telemedicine are now taking a back seat—the development of Internet technologies allows us to provide the high quality of communication which is necessary for video consultations, transmitting information about the state of health, etc. However, not all countries have real coverage of high-quality Internet connection to all territories, and also not all countries provide clinics with the necessary equipment, because this requires large expenditures on the appropriate infrastructure.

In these conditions, the economic and legal problems of using telemedicine technologies become more relevant, or rather, the existing restrictions and obstacles in this area.

Indeed, according to WHO, the most frequently cited barrier to the implementation of telemedicine solutions globally is the perception that the cost of telemedicine is too high. While developing countries are more likely to consider resource issues such as high costs, undeveloped infrastructure, and lack of technical expertise to be barriers to telemedicine, developed countries are more likely to consider legal issues surrounding patient privacy and confidentiality [1].

The Russian Federation is a sufficiently developed country in terms of technology, but with an insufficiently developed economy. That is why most of the problems of using telemedicine technologies, which are typical for both developed and developing countries, are found in Russia. At the same time, Russia has adopted legislative and other regulatory acts regulating the provision of medical care using telemedicine technologies. In this regard, it seems that the review of Russia's experience in this area will help to identify problems that are typical for other countries, as well as to develop approaches to overcoming existing obstacles and restrictions.

2 Materials and Method

According to WHO, legal considerations are a major obstacle to telemedicine uptake. These include an absence of an international legal framework to allow health professionals to deliver services in different jurisdictions and countries; a lack of policies that govern patient privacy and confidentiality visà-vis data transfer, storage, and sharing between health professionals and jurisdictions; health professional authentication, in particular in e-mail applications; and the risk of medical liability for the health professionals offering telemedicine services [1].

Economic restrictions are no less significant. Economically developed countries consider telemedicine primarily as an instrument of reducing permanently increasing costs of health care. Developing countries usually use telemedicine as a way to solve the problem of access to medical care for the population-especially for people living in hard-to-reach localities.

Understanding the significance of these and other issues leads to the fact that not only representatives of individual expert communities and States [2–5], but also authoritative international organizations express their concerns in this regard. The examples are the results of reviews and studies by the world health organization [6] and the Organization for economic cooperation and development [7].

Figure 1 shows the barriers and enablers of telemedicine use highlighted by respondents, by number of reporting countries [7].

In order to understand the essence of the restrictions under consideration better, it is necessary to study the system of legal and economic relations that arise between different participants in the provision of telemedicine services, focusing on international experience in this field. The economic problems of using telemedicine technologies should be assessed by analyzing the economic interests of each of

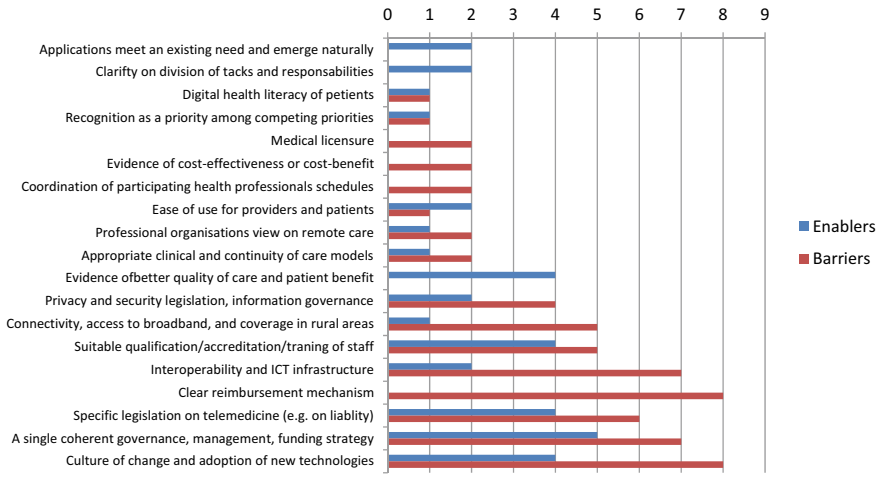

Fig. 1 Barriers to the wider use of telemedicine don't outnumber the enablers

these participants. The main focus should be on determining the ratio of additional costs and additional benefits for each participant associated with the provision of telemedicine services.

3 Results

3.1 Legal Aspects of Implementing Telemedicine Technologies

One of the most common legal restrictions on telemedicine development is licensing. Moreover, problems with licensing in different countries may be different. So, once the United States faced the problem of being not able to provide telemedicine services to residents of other States by a doctor who practices in another State. In the United States, as in many countries, a license is issued not to a clinic, but to a doctor. The health care system in the United States is highly fragmented due to the fact that each state has its own laws in this area. Therefore, the doctor receives a license to operate only in his state. Such restrictions force us to look for ways to harmonize the legislation of different States.

In Russia, a clinic usually receives a license. In itself, this circumstance does not create restrictions on the use of telemedicine technologies. Moreover, it is possible to obtain a license and a private practitioner. More important is another circumstance. There is no legal relationship between the consulting doctor and the doctor being consulted, or the doctor and the patient—they only occur between clinics where doctors work. For the same reason, a private doctor will provide telemedicine consulting services to a clinic, not to a doctor. The consequences of wrong recommendations, or, on the contrary, incorrect application of recommendations, will not be borne by the doctor, but by the clinic. This reduces the legal responsibility of doctors for the quality of medical care provided. In Russia, the degree of legal and financial responsibility of a doctor, including providing telemedicine services, is quite low, that in our opinion does not meet modern international requirements. It is necessary to change the legislation aimed at increasing the responsibility of doctors while increasing the degree of their professional protection through insurance mechanisms, etc.

A license in Russia is issued at the place of medical care. The license specifies the place of medical care. Traditionally, these are the facilities of the clinic (with the exception of providing emergency medical care and providing medical care at home for patients). The license assumes that the place of providing such medical services as medical consultation when a patient visits a doctor is the doctor's office. But there is a question: what is the place of service when providing the same service in the mode of telemedicine consultation: the location of the doctor or patient? This issue is not regulated by law.

There is another restriction related to licensing. Linking the license to the place of medical care does not allow for telemedicine consultation by a doctor from home. That is, when conducting a telemedicine consultation, the patient may be at home, but the doctor may not. The doctor should consult only from the clinic's territory. In conditions where telemedicine consultations, transcripts (descriptions of images, electrocardiograms, etc.) do not require anything other than the knowledge of the doctor and the equipment necessary for distant contact with the patient or other doctor, these restrictions seem excessive, inhibiting the widespread development of telemedicine technologies, limiting their use when necessary for consultations in emergency cases.

Cross-border legalities are a concern for developing countries that use telemedicine services to connect with health professionals from more than one country. A crucial question that needs to be addressed in this scenario is: Which country's law applies or has jurisdiction over the service? [4].

And even if such problems arise within states (as can be seen in the example of the United States), it becomes clear that providing telemedicine services to residents of different States faces even greater difficulties.

A host of problems can occur when the health laws of participating countries conflict. What happens if a mistake occurs? Who takes ultimate responsibility for the service and care provided? Unfortunately, these types of legal questions are insufficiently addressed by national health laws at present [3].

Uncertainty may impact the use of such services in both industrialized and developing countries. Additionally, the lack of information about legal policies and guidelines concerning the use of telemedicine in the clinical context may be a deterrent to the adoption of such practices [1].

Information systems involved in telemedicine technologies are subject to increased requirements in terms of information security and data protection. For example, if personal information about Russian citizens is processed, it must be located on the territory of the country. To exchange data with other systems (such as clinic information systems or medical information systems), they must be connected to a unified identification and authentication system. In addition, the doctors involved in providing telemedicine services must be registered in the unified identification and authentication system.

This effectively eliminates the use of cloud technologies for storing personal data, as well as direct spontaneous telemedicine contacts between Russian doctors (clinics) and doctors in other countries.

And this is despite the fact that one of the priorities for the development of Russian health care is a promotion of growth in the export of medical services. One form of such export could be the development of telemedicine consultations, primarily for the countries of the former Soviet Union. The above-mentioned problems of differences in the legislation of different countries hamper this process. This also limits the ability to get advice from doctors from leading foreign clinics, and to introduce advanced foreign medical technologies more widely.

Faced with such problems, the Russian Government took an unprecedented step: it created The Skolkovo innovation center (a suburb of Moscow), on the territory

of which foreign clinics can be established and operate within the framework of the legislation of their countries (including license requirements, etc.). It seems that such projects will contribute to the international integration of health care in different countries, create prerequisites for coordinating legislation in the field of health care, including the use of telemedicine technologies.

The development of telemedicine is also hindered by the availability of patient information in electronic form. The consulting doctor must have access to patient information, the results of previous studies, etc. Although electronic medical documents are becoming more common in Russia, it is too early to say that this has become the norm. The problem lies both in the availability of medical documentation in electronic form, and in the possibility of access to it by doctors of other clinics. Obviously, the development of informatization from this point of view should be connected with the possibility of storing relevant information in an easily accessible format (for example, using cloud technologies), when a doctor from another clinic can get access to these documents with the consent of the patient.

In contrast to the usual face-to-face visit, telemedicine consultations are subject to clear documentation in the form of an electronic record. Therefore, following the results of telemedicine consultations, it is much easier to identify possible errors made by the doctor, facts of unethical behavior towards the patient, etc. This is one of the limiting factors for the development of telemedicine.

According to the World health organization, the risks of medical liability of specialists who provide telemedicine services are one of the main obstacles to their implementation worldwide, along with the lack of an international legal framework that allows specialists from different countries to provide services [1].

On the one hand, this requires the creation of measures to encourage doctors, and on the other hand, increasing the protection of doctors through the mechanism of professional insurance, etc. This is especially important for Russia, since, unlike many countries, Russia has not yet implemented a system of professional liability risk insurance, although the right to such insurance has long been enshrined in law.

Moreover, in our opinion, Russia currently has an excessive system of control over the provision of telemedicine services. A medical organization, after receiving the recommendations of medical workers of clinics under the jurisdiction of the Ministry of health of the Russian Federation, must, no later than one business day from the date of receipt of this information, post information about insured persons in respect of whom these recommendations were received in the information system of compulsory medical insurance. The insurance company monitors the implementation of the recommendations of medical workers of clinics subordinated to the Ministry of health by medical organizations, and conducts an examination of the quality of medical care. Although there are no sanctions for non-compliance with the recommendations received in the telemedicine consultation section, other violations may be detected during inspections. In any case, clinics are not interested in additional checks by insurance companies. All this hinders the development of telemedicine technologies.

An important aspect of the application of telemedicine technologies is the question of the rights and obligations of citizens to telemedicine services, as well as

whether the use of telemedicine technologies is the right or duty of doctors and/or clinics. From the patient's point of view, the most relevant issue is the possibility to ask a doctor of any medical organization for them, the right to choose a doctor, etc. When it comes to telemedicine services provided on a commercial basis, the entire agreement of the parties is decided, reflected in the contract. But it is obvious that the unlimited right to choose a consulting doctor when providing telemedicine services comes up against the physical capabilities of doctors, the system of financial relationships, which in this case becomes extremely difficult. Therefore, in most countries that have established a legal framework for the use of telemedicine technologies, there is no unrestricted freedom to choose a consulting doctor. In fact, it is a matter of regulating how the given choice rights can be implemented in certain cases. For example, in the Russian Federation, the right of a patient to choose a doctor (including when conducting telemedicine consultations) applies only to the provision of primary medical care (general practitioner). The right to choose a doctor-consulting cardiologist, neurologist, etc. when providing free medical care is not possible.

3.2 Economic Problems of Implementing Telemedicine Technologies

Recently, a large number of publications have appeared that provide information about the high economic efficiency of using telemedicine technologies.

However, it is necessary to take into account that they are mainly concerned with evaluating the use of telemedicine technologies in the most developed countries, such as the United States [5] and Japan [2].

In developed countries, where the level of doctors' salaries is quite high, the cost of material resources necessary for the application of medical technologies (the cost of equipment, Internet connection, etc.) occupies a relatively small share in total costs. For developing countries, these costs can be considered very significant. Therefore, developed and developing countries may differently evaluate the effectiveness of telemedicine technologies.

As noted in the WHO's review, genuine questions remain as to whether telemedicine provides the most cost-effective solution in areas where resources are scarce and simply meeting the basic health needs of the population is of utmost priority, as is the case in the majority of developing countries [1].

It is also important to consider who bears the specific costs of providing telemedicine services. Thus, based on the results of the telemedicine consultation, the departure of an airplane or helicopter that was planned for the evacuation of the patient (for delivering the patient from a remote locality, etc.) may be canceled. In this case, the state will save a lot of money on air ambulance, but this savings will not affect the economic situation of the clinic where the patient receives medical care and the salary of the doctor.

Therefore, a clear analysis is needed not only of the total costs of providing telemedicine services, but also of the distribution of these costs (as well as the benefits received) between the parties involved in providing medical care, including the patient.

Indeed, in a number of cases, all or almost all of the benefits from the introduction of telemedicine technologies go to the patient: he does not need to get to the clinic from remote and/or hard-to-reach localities, the waiting time for medical care and/or receiving examination results is reduced, etc. The clinic is still forced to maintain its facilities, pay for the work of the doctor, while incurring additional costs for the purchase of equipment necessary to provide telemedicine consultations.

In this regard, it is necessary to assess in each case whether investments in the provision of telemedicine services are "necessary expenses" or "investments" that give a positive economic effect.

By "necessary expenses", we mean the costs without which the proper provision of medical care is impossible in terms of ensuring a guaranteed level of availability and quality of medical care. For example, the provision of medical care in many cases is not possible without medicines. The "necessary expenses" may be quite high and unrecoverable from the point of view of the traditional understanding of this term. From the point of view of telemedicine, this may be the cost of creating infrastructure (laying cables for Internet communication or purchasing equipment for satellite communications). If we are talking about really hard-to-reach regions, the absence of these costs, which do not allow for Internet connection, may deprive a significant part of the population the opportunity to receive at least certain types of assistance in a timely and sufficient manner.

It is necessary to allocate criteria for assigning costs to "necessary" ones. So, at present, medicines that can successfully treat many forms of cancer have been invented. However, not all of them are used in practice to provide free medical care for the population due to their excessive cost. Since public resources for health care are limited, there is always a dilemma: whether to use available funds to buy expensive medicines to save the lives of a small number of patients, or to buy more other, less expensive drugs to save the lives of more patients. Similarly, not all telemedicine costs will be considered "necessary". For example, the costs of purchasing and installing devices for remotely changing the parameters of vital functions of the patient's body at home may be considered as not related to "necessary" if the patient's health does not require constant monitoring and allows them to independently apply to the clinic for the necessary measurements. However, if these same costs are paid back and make a profit by providing telemedicine services on a paid basis at the expense of the patients themselves or within the framework of voluntary medical insurance programs, they will be considered as "investments in telemedicine".

We use the term "investment in telemedicine" in the traditional sense as a cost that should pay off and make a profit. "Investments" may include, for example, investments by leading medical clinics in the creation and equipping of units that will provide telemedicine services to other clinics or to the people on certain commercial terms. Since "investments" in telemedicine technologies, like any other investments, can be both profitable and unprofitable, the criteria for distinguishing "necessary

expenses" from investments is not the financial result in each case, but the justification for the purpose of investment.

However, evaluating efficiency, payback, or loss is important in both cases. Unprofitability (the degree of unprofitability) is an important criteria that can limit the use of telemedicine technologies in a particular project.

Telemedicine services are usually considered not as independent types of medical care, but only as information technologies that contribute to the provision of medical care [6].

Therefore, in our opinion, when evaluating the effectiveness of telemedicine services, it is sufficient to limit yourself the additional costs and additional results achieved through their use, and not to take into account all the costs associated with the use of telemedicine technologies. First, it simplifies calculations by facilitating the wider use of performance estimates. Second, it allows you to more clearly identify the costs related not to the provision of medical care itself, but to the use of telemedicine technologies. Third, it should be taken in mind that in a number of cases, additional costs may not be at all or minimized. For example, it would be wrong to take into account the cost of a computer, payment for an Internet service provider, etc. as the cost of a telemedicine consultation, if all this was present earlier (before the provision of telemedicine services).

At the same time, in our opinion, generally accepted methods of pharmacoeconomical analysis (for example, CEA—cost-effectiveness analysis) can be used for this purpose.

Table 1 shows a comparison of additional costs and additional benefits associated with the use of telemedicine technologies.

It should be noted that the costs of the state and clinics are not combined by chance. When it comes to public health, in many cases it is impossible to clearly attribute certain costs to the costs of the state or clinics (including when it comes to mandatory health insurance). Indeed, the cost of purchasing computer equipment, communications equipment, etc.—expenses are usually carried out directly by the clinic. But they receive resources for this either from the state, or the state creates financial mechanisms for this through the health insurance system.

Another important point is that the table only considers economic costs and benefits. In practice, there are other factors: increased risks of professional responsibility, the possibility of reducing the number of contacts with infected patients, etc. They are not considered in this case, but they should be taken into account when making decisions about the development of telemedicine technologies.

Another conclusion that follows from the table: telemedicine consultations themselves do not provide direct benefits for the doctor—he spends the same time on the patient as during a face-to-face visit. Against the background of higher responsibility of doctors due to fixing the content of consultations in electronic form, it is necessary to consider creating incentives for doctors to use telemedicine technologies.

One of the factors hindering the development of telemedicine technologies is the fear of uncontrolled growth in the volume of telemedicine services, which leads to higher overall costs in the health sector. So the volume of face-to-face visits is somehow limited by the available facilities, doctors, etc. the Wide development of

Table 1 Comparison of additional costs and additional benefits, related to the use of telemedicine technologies

Participants	Additional costs	Additional benefits	Comments
Patients	Remote communication equipment, Internet payment, purchase of electronic signature	Saving time and money on the way to the clinic; on the possible payment of the hotel; increasing the efficiency of receiving medical care	For active users of computer equipment and the Internet, the additional costs are relatively small, and the savings can reach large sizes
State	Remote communication equipment, Internet payment, information security, staff training, etc.	Savings achieved by optimizing the health system at the national and/or regional levels	The government's costs for telemedicine from an economic point of view usually do not pay off, bringing only an indirect effect in the form of availability of medical care, etc. But the main economic benefit is based on the increasing of accessibility goes to patients
Clinics		The possibility of optimizing costs at the level of specific clinics, using technologies (specialists) that are not available in the clinic itself, generating revenue from the commercial use of telemedicine, etc.	For large self-sufficient clinics, there is no need to resort to telemedicine services—it can be interesting mainly only from the point of view of its commercial use, selling its services to patients or other clinics
Doctor	–	–	If the doctor provides telemedicine consultation instead of face-to-face, there are no additional costs or labor savings. However, when providing telemedicine services as additional work on a commercial basis, an additional source of income may appear. But telemedicine services can be seen as a means to improve the quality of treatment by getting advice from other doctors

telemedicine consultations can lead to a significant increase in the volume of services that must be paid by the state or insurance companies. It is not by chance that in many countries there is a clear trend on the part of insurance companies to limit the amount of paid medical care.

According to the Organization for economic cooperation and development, one of the most common reasons for holding back the development of telemedicine technologies is the lack of a clear cost recovery mechanism for conducting telemedicine technologies [7].

Similar results were obtained in a special study conducted in 2017 in the United States [8].

The availability of telemedicine services to the population, as well as any medical services, is determined by sufficient resources. No country in the world can provide the population with free medical care. Therefore, governments of countries or insurance systems impose restrictions on the set of drugs, technologies, equipment, etc. Such restrictions apply in Russia too. For example, the set of equipment used to provide free medical care for the population is regulated by the standards approved by the Ministry of health for equipping wards, offices, etc. These standards do not always provide equipment for providing telemedicine services. Thus, the standards for equipping cardiology rooms in regular clinics do not include equipment for conducting telemedicine sessions (while the doctor's offices in specialized cardiac clinics provide such equipment). Therefore, it is not allowed to buy equipment for cardiac offices that is necessary for conducting telemedicine services at the expense of state sources. The corresponding equipment standards were approved before the adoption of the law that legalized telemedicine, and will be gradually revised. But this example quite well illustrates the existence of numerous, sometimes hidden, obstacles to the practical development of telemedicine, even in the presence of appropriate legislation.

In the case of telemedicine technologies, states find themselves in an ambiguous situation. On the one hand, it is necessary to stimulate the development of telemedicine technologies as providing higher access to medical care for the population. On the other hand, telemedicine technologies are not cheap, and their widespread use should be justified by economic or medical, social reasons—unjustified provision of telemedicine services increases the total cost of health care. Therefore, flexible payment mechanisms for telemedicine services by the state and/or insurance organizations are necessary.

Let's consider the attempts to solve this problem in the Russian Federation. The Russian healthcare financing system focuses on providing free medical care for the population. Therefore, for the widespread use of telemedicine technologies, first of all, the interest of doctors who provide telemedicine services to patients is necessary. We are talking about adequate remuneration for their work. In cases where telemedicine services are provided by doctors to each other, there is also a need for interest not only from doctors who provide telemedicine services, but also from doctors who seek advice from doctors in other clinics. In a situation where the financial relationship of doctors regarding the provision of telemedicine services is mediated by the relationship between the two clinics, it is necessary to take into account

the financial interest in conducting telemedicine consultations of the clinics themselves. The possible discrepancy between the interests of clinics and their doctors in conducting telemedicine consultations creates a rather complex and contradictory system of relations.

Within the framework of the compulsory health insurance system, the simplest mechanism for stimulating the provision of telemedicine services is provided for hospitals. Increasing coefficients are applied to the rates for their services that pay for inpatient care, which should encourage hospitals to use telemedicine services in the form of consulting doctors of other medical organizations. However, such a mechanism does not contain a clear economic justification for the size of the tariff increase. There are no clear criteria to determine by what amount you need to increase the rates for a particular clinic (the number, types of telemedicine services provided, etc.). These issues need more detailed methodological elaboration.

In terms of funding outpatient care, there are significantly more cost recovery options:

1. If the polyclinic is funded according to the per capita standard for the number of attached residents, then separate tariffs for telemedicine consultations are not set. In this case, medical organizations do not have interests in the widespread use of telemedicine technologies—they will not receive additional income for telemedicine consultations of patients.
2. In some cases, a system of mutual settlements between clinics is used. If medical care (including telemedicine consultations) insured persons is not in the clinic, to which it is attached, the cost of telemedicine services which is paid through the clinic and will be deducted from the amount of per capita financing of the polyclinic which the patient is attached to. In this case, a third-party medical organization is interested in providing telemedicine services.
3. Separate tariffs for telemedicine consultations are set when providing medical care to residents of other regions, as well as for clinics that do not have an attached population. In this case, the telemedicine service is additionally paid for by the insurance company. This also creates the interest of the clinic to provide telemedicine services.

As you can see, not all payment methods used for medical care create interest for clinics in providing telemedicine services. This is also overlaid by the peculiarities of the Russian system of compulsory medical insurance, when the main risks are not borne by insurance companies, but by clinics [9].

This is the situation when economic problems should be considered not from the point of view of sufficient funds, personnel and other resources, but from the point of view of the economic interests of participants in economic relations [10, 11].

The interest of specific medical professionals in providing telemedicine services is determined by the existing payment systems in clinics [12–15].

4 Conclusion

The analysis allows us to draw the following conclusions.

When assessing the prospects for the development of telemedicine technologies, it is necessary to take into account the goals and objectives of specific countries. These can include saving resources, improving the availability and/or quality of medical care, speeding up the receipt (interpretation) of research results, and so on.

For economically developed countries, telemedicine is a way of reducing the ever-increasing costs of health care, and for developing countries, it is a way of increasing the availability of medical care for residents of remote and hard-to-reach localities.

In countries with different levels of economic development, the assessment of the effectiveness of various forms of telemedicine technologies may differ both because of the priority of expectations from telemedicine, and different cost structures.

The savings (benefits) from telemedicine should be calculated at the level of each institution (and for regional projects—at the regional level), for each specific service.

Against the background of the broad potential prospects offered by telemedicine, the analysis of restrictions and other constraints that hinder the broad development of telemedicine is particularly relevant.

International reviews, including those conducted by reputable organizations such as WHO and the OECD, show that economic and legal problems are the main obstacles to widespread adoption of telemedicine technologies.

The experience of the Russian Federation (which combines elements of both developed and developing countries) in solving problems arising from the introduction of telemedicine technologies may also be interesting to other countries.

Digital Socialization Agents in Adolescence

Sergey L. Kandybovich, Tatyana V. Razina, Aleksandr S. Solodukho, and Galina A. Fofanova

Abstract The *purpose of the work* is to study the features of socialization in adolescence and the role of the digital environment in this process. The *methods of research* were free pair by association, private semantic differential, frequency analysis and content analysis, as well as descriptive statistics procedures and factor analysis as data processing methods. The *results* showed that today's youth have a clear differentiation of socialization environments with a preference for the digital environment. The leading agents are the global Internet network, social networks and messengers. Cognitive patterns of perception of agents of digital socialization Ɔ "malicious–well meaning" and "regressive–progressive" have been established. The main characteristics and directions of socialization in the digital environment have been established: the digital environment in combination with the values of individualism, hedonism, comfort, as well as technologies contributing to their achievement are presented by young people as a field for creativity and self-actualization. At the same time, young people do not have an attitude to training, to continuous professional development, self-improvement, self-overcoming and work. *Conclusions/recommendations.* The data obtained make it possible to predict possible ways of further socialization and economic behavior, as well as to formulate a number of practical recommendations in the field of management and education.

Keywords Digital technologies · Digital agents · Socialization · Sociocultural environment

JEL Classification Z1

1 Introduction

The processes of digitalization of all spheres of society have a natural consequence of changing the very structure of society, as well as the social processes taking place in it. On the one hand, this is due to qualitative changes in the means and methods of work, and on the other—the transformation of all learning, cognitive processes of modern man. The digital environment has affected the global patterns of growth, development, and socialization of man, qualitatively changing the entire sociocultural environment. Such transformations are necessary for a person to be able to function successfully in the digital environment and successfully adapt to it. This entails changes in all sociocultural and socio-psychological practices of growing up, learning, which have existed until now. The intergenerational differences between today's (and tomorrow's) youth and middle-aged people are amplified many times not only by value-normative differences, but also by cognitive-behavior differences. At the same time, there are some disagreements among researchers in assessing the extent of these differences [1]. Digital technologies are the main agents of socialization for modern youth. They become especially relevant at the stage of young people's entry into a broad social environment—in adolescence, when they should gain experience of social contacts, when there is an awareness of themselves and as a member of society and their place in it, when life strategies are formed in the family, labor and economic spheres. Studying these processes today will make it possible to model the image of tomorrow's society, labor and economic behavior of young people, the nature of social and economic relations. This leads to the formation of a fundamentally new type of society.

The answer to the stated questions is unthinkable without defining what is meant by the socialization of the individual. To date, the content of this category has undergone significant substantive changes. The recognition by the scientific community of the changes associated with the organization and functioning of the social environment of personality development has led to both expanded interpretations of the concept and specific subcategories that convey the specifics of this process. In the classical domestic interpretation, socialization of the individual is seen as a process and result of the subject's assimilation and active reproduction of social experience [2]. At the same time, it is unequivocally emphasized that socialization is a combination of natural and systematic influences on the individual's experience and worldview.

The development of information environment, the increasing pace of digitalization of everyday life of modern personality have led to the fact that public experience and regulations have acquired the possibility of material fixation and long-term storage in accessible to sensual perception of sign, symbolic and figurative forms. These changes have logically led to the emergence in the social sciences of a whole series

of concepts that attempt to convey these changes. These concepts include information socialization, media socialization, cybersocialization and digital socialization.

Information socialization is considered through the category of information space. It is defined as a relatively new social institution, which is a source of information about the diversity of knowledge that contributes to the successful functioning of a person in society [3]. At this, it is emphasized that the information space is much wider than the Internet communication, and personal preferences are determined by a wide range of factors that constitute the personal history of the subject of information socialization.

Western tradition also uses the term "media socialization". Researchers consider this category through the prism of information sources, represented by both new and traditional media. This type of socialization manifests itself both in the formation of a person's circle of reference sources of information, the development of qualification to use these sources, and the experience of direct Internet communication [4]. In this tradition, groups of "digital natives" and "digital immigrants" are distinguished by their age, fundamentally differing in their interaction with modern information technologies, in particular, with media socialization agents [5].

To a lesser extent, the term "cybersocialization" is used in Russian social science [6]. In considering this phenomenon, the author focuses on qualitative changes in a subject's personality that occur as a result of the use of Internet information resources, as well as in the course of Internet communication with virtual socialization agents. At the same time, cybersocialization is viewed as a rather autonomous phenomenon from the external (offline) environment.

The term "digital socialization" has relatively recently been introduced into scientific use. Initially, the term was used in the narrow context of learning by experience based on behavior in Internet communications [7]. Subsequently, the category began to be considered more broadly, given the changing characteristics of the modern information environment. In domestic social psychology, "digital socialization" is currently interpreted as an evolutionary development of the concept of "information socialization". This phenomenon is interpreted as "a process mediated by digital technologies of acquiring and assigning to a person the social experience acquired in online contexts, reproducing this experience in mixed offline/online reality and forming his or her digital personality as part of the real personality" [8]. Information socialization implies greater reliance on sources of information, while digital socialization implies an emphasis on using experience in a synthetic environment that combines the real and virtual worlds. In the context of the increasing availability of the "mobile" Internet and the development of technologies of augmented and virtual reality, this content point most adequately characterizes the complex socializing environment, in which modern young people are included.

At the same time, in the context of socialization it is appropriate to talk about identity rather than digital personality [9]. The presence of accounts in various social networks, messengers, Internet sites and thematic Internet resources suggests that users focus on different sides of their own selves. This problem allows to extend the effect of digital multitasking [10] on the personality of the subject of socialization. In the context of digital socialization, it raises such issues as internal consistency of

digital identity, multiplicity of digital identities, questions of contextual consistency of the manifestations of a set of "digital identities" in a wide range of situations of online and offline activity of the subject.

An important aspect of socialization in the modern information society is the question of its agents. Traditionally, in domestic approaches to socialization, people are most often defined as agents. Primary agents include representatives of the nearest informal environment and family system, while secondary agents include representatives of social institutions [11]. On the other hand, information transmission channels and intermediaries can also be considered as agents, providing both transmission and fixation of elements of social experience—from simple models of communicative behavior to the transmission of core values characteristic of society as a whole and its individual segments.

In our view, such a "connection" can be justified by the fact that the space of "mixed forms" of socialization combines both social and online worlds. One of the characteristic features of interference of these worlds is the possibility of manifestation of communicative traces of the "past" in them. This is well illustrated by the metaphor of M. Castells, who defines the formed contemporary culture as "real virtuality". Its hallmark is the complete immersion of the material and symbolic aspects of a person's life into virtual communication. As a result, communication and the channels supporting it uninterruptedly merge (the agent and the channel acquire inseparable status), and communication itself becomes not only a tool, but also a goal [12]. As a result of this merger, precedents may emerge that are fundamentally different from the current paths of young generations' socialization.

The purpose of the work is to study the features of socialization in adolescence and the role of the digital environment in this process. It was suggested that for today's young people, the digital environment is the preferred medium for practicing social skills and primarily for interaction with peers.

2 Methodology

Private semantic differential is taken as a research method. Sampling included 202 students of higher education institutions of the Russian Federation aged 17–25 years (average—18.3 years), men 49.3%, women 50.7%.

To establish the scales of the private semantic differential using the free pair by association method on a sample of 54 subjects, the associative space of the concept "Digital environment" was investigated. Based on frequency analysis, nuclear associations of young people with this notion were determined. On the basis of these associations, reflecting the qualities of the digital environment, 21 bipolar scales were drawn up: 1. Thoughtful–Spontaneous; 2. Flexible–Rigid; 3. Useful–Harmful; 4. Energetic–Sluggish; 5. Active–Passive; 6. High-quality–Defective; 7. Profitable–Loss-making;

8. Rich–Poor; 9. Progressive–Backward; 10. Responsible–Indifferent; 11. Scheduled–Chaotic; 12. Effective–Useless; 13. Stable–Crisis; 14. Comfortable–Uncomfortable; I5. Professional–Amateur; 16. Realistic–Fantastic; 17. Peaceful–Aggressive; 18. Humane–Cruel; 19. Free–Inhibited; 20. Moral–Immoral; 21. Friendly–Dangerous. The intensity of the characteristic on each scale was estimated from "−3" to "+3". The content analysis of the associative field was also used, which enabled a semantic interpretation of the observed phenomena.

The second stage of the study was a semantic differential procedure. The sample consisted of 154 university students. The objects of evaluation were: "computer", "mobile phone", "Internet", "social network", "messenger", "artificial intelligence", "television", "book", "profession", "self-realization", "work", "learning", "creativity", "teachers", "relatives", "friends", "myself".

The results obtained on all scales were subjected to factor analysis (main component method, varimax normalized). Each factor included only those scales whose factor weight exceeded 0.7. The first factor, which we conventionally denoted as "goodness", included the scales "Useful–Harmful" (0.85), "Friendly–Dangerous" (0.83), "Comfortable–Uncomfortable" (0.72). The second factor we denoted as "innovations" and included the following scales: "Progressive–Backward" (0.91), "Realistic–Fantastic" (0.77) and "Free–Inhibited" (0.71).

3 Results

The two global factors obtained can be interpreted as cognitive schemes through which modern youth perceive the digital environment, society and their place in it. These schemes can further serve as a basis for long-term life strategies, including labor and economic behavior, setting a socio-cultural vector for further development in the digital environment. The first factor (cognitive scheme) was defined by us as "well meaning". Thus, any external, social or digital object young people interpret primarily on the basis of whether it can bring good or evil to them personally, whether it is worth staying away from that object or using it to achieve goals. Content analysis of the associative field of the concept "digital environment" suggests that young people are rather passive towards new technologies, perceiving them as if they were originally created to make people's lives easier or to harm them. In fact, it is not young people who have no idea that evil or good is determined not so much by technology itself as by its features, conditions, purposes and consequences. Such passivity suggests a high degree of readiness for consumer behavior and, in particular, non-critical perception of advertising, as well as difficulty in critically assessing the reliability of information.

The second factor (cognitive scheme)—"innovation"—evaluates the degree of modernity of objects, and how their use can be evaluated—how it slows down progress, pulls it into the past, how it is morally outdated, or vice versa—how it contributes to progress, or it is its result or the novelty, and on which basis the progress will take place in the future. It is a factor that reflects the quality of social

and digital objects, with the regressive factor assessed as "bad", unsuitable for use, and progressive as "good". It is no coincidence that the "Progressive–Backward" scale has the maximum load in this factor.

The obtained factors reflect a categorical, cognitive scheme through the prism of which the digital environment, digital technologies, future labor, educational and creative activities and their place in the life of a young man, i.e. a significant part of the socio-cultural environment are perceived.

The obtained schemes allowed to characterize all evaluation objects and identify preferred socialization agents (Fig. 1). Such agents as "Internet", "social networks", "messengers" and mobile phones are seen by young people as well meaning and progressive. Young people see themselves as being in this digital environment together with other actors—"friends". This social and digital environment is seen by young people as a field for creativity and self-realization. It is these agents of socialization that young people perceive as the most preferable for themselves and want to use them as an environment providing the most attractive activities. This attitude corresponds to the values of individualism that have been actively implemented in recent years in the post-Soviet space. Accordingly, young people will choose the sociocultural environment as favorable for themselves, where the values of individualism, hedonism and comfort will be presented to the maximum extent. It is in this way that socialization will be carried out and the information environment will provide young people with all the technological opportunities for this.

Another significant group of objects is a well-meaning but regressive one that includes such objects as "computer", "TV", "book", "learning", "teachers", "relatives". These agents of socialization are not assessed as playing a decisive role in the formation of a young person. According to the content of this group, the process of learning and its subjects are seen by young people as the stage they have already passed, i.e., in fact, they believe that they have nothing to learn. This fundamentally

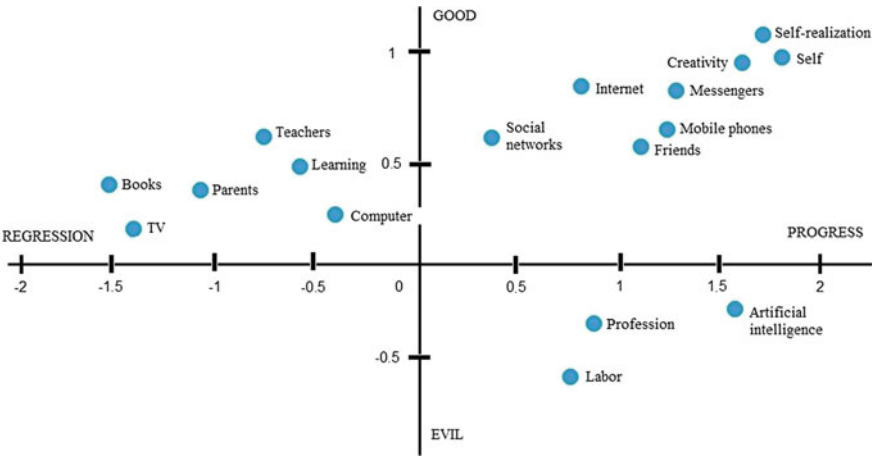

Fig. 1 Semantic space of socialization agents

contradicts the current situation of constant updating of the technological environment, which, on the contrary, involves continuous learning, improving one's level and skills. Accordingly, in this position for young people there is a significant danger—after some time, young people risk becoming unsuccessful and unadaptable unless they form an attitude to learning, continuous training, self-improvement.

It should be noted that despite all the craving for progress and modernity, young people, however, continue to watch TV, work on the computer, study, communicate with parents, etc. On the one hand, it can provoke an inner conflict (when the real me does not fully coincide with the ideal me). On the other hand, the gap between the assessment of the socialization agent and its use suggests the existence of some imposed social, digital trends. In other words, young people could read books and communicate with parents more often, but the massive propaganda of digital technologies predetermines the choice of young people, putting them in the dilemma of doing what they like or being modern.

The third group—malicious and progressive—consisted of three objects: artificial intelligence, profession and labor. On the one hand, there are high hopes for the emergence of artificial intelligence, but on the other hand, it raises certain concerns. Not least, such assessments may be associated with the influence of the products of the modern film industry, where the topic of artificial intelligence as an opponent of man has been raised many times. It is indicative that young people see work and profession as a matter of the future, but assess it extremely negatively, unlike creativity and self-realization. Perhaps, the location in close proximity of the object "artificial intelligence", as well as employment shows the unconscious desire of young people to shift all work on technology over time (automated and robotic lines, controlled by artificial intelligence), while for themselves, young people leave self-realization through creativity. Content analysis has shown that young people's ideas almost completely lack the concept of "overcoming" (themselves, their nature, their desires, etc.), which the human culture and socialization have been built on over the past millennia. There may be another danger to young people's lives afterwards—when they do not have the skill and attitude to make deliberate efforts to create some socially useful products, then, when previous generations leave, today's young people will end up in a situation where they lack the most vital goods and services. Creativity, as opposed to work, is regarded as a pleasure, which is got primarily for themselves. The youth do not see that creativity also presupposes a purposeful effort and overcoming of themselves and perceive it one-sidedly—as a spontaneous self-representation. Thus, socialization agents associated with working life are seen by young people as the most undesirable ones and, if possible, this sphere of social behavior can be avoided in every way.

4 Conclusion

Thus, the socialization processes of modern youth are greatly influenced, on the one hand, by digital socialization agents—the Internet, social networks and related

technical devices, on the other hand—by the values of individualism. The priorities in communication and in the choice of social environments are also quite closely related to the use of various digital objects. This creates a new space of socialization—the digital one, which for the first time is determined not only by the characteristics of a social group, but also by the technological environment and digital means of communication. This makes it possible to predict ways of further socialization and economic behavior, namely, the preference for creative types and forms of activity, if possible through virtual reality (work on the Internet, teleworking, etc.). The values of comfort will prevail over those of economic solvency, which will significantly reduce the possibilities of economic means of managing society. Nevertheless, consumption of goods and services will be quite intensive, but will be rigid in line with the cognitive framework of "well meaning–malicious" and "regressive–progressive". Accordingly, the products and services presented to young people under the brand of "good intentions and progressiveness" will have a high consumption index. Young people's lack of commitment to regular learning and working efforts may lead to significant labor shortages in all sectors of the economy over time. An alternative to this may be the introduction of appropriate technological developments with artificial intelligence, but the current state of this branch of science and technology does not allow to assume that, in the next 20–30 years, it will be able to compensate for all the deficit arising in this segment. Accordingly, the second way is to organize training and educational work with young people, aimed at correcting the ideas about labor and economic behavior.

Application of Digital Technologies in Public Finance

Nadezhda S. Matveeva, Julia A. Lebedeva, and Olga A. Petrina

Abstract The results of applying digital technologies in state financial system are analyzed. Development and improvement of state and municipal administration is impossible without transition to digital form of running basic business processes. The article used methods of content analysis of legislation in the field of digitalization and state financial and budgetary management, comparative analysis of data on implementation of programs and projects of digitalization of economy in Russia, as well as methods based on the system approach with description of digital solutions used in the domestic budgetary system. As a result, it has been revealed that a comprehensive approach to the development of digital solutions in the system of state financial control will improve the efficiency of use of budget funds and management of the budget system in the Russian Federation. Increased transparency and availability of data for all levels of government is necessary for sustainable growth and development of both the budget system and the economy as a whole.

1 Introduction

The Fourth Industrial Revolution or "Industry 4.0" is taking place all over the world, and Russia is no exception. This approach affects all kinds of digital transformations in the economy and life activities, the introduction of the latest innovative business models and technologies in production.

Foreign experience shows that the digitalization of the public administration system and the introduction of innovative information and telecommunication technologies into the work of government agencies are objectively necessary and lead to progress in various economic and public spheres. The relevance of digitalization in the management of state budget funds is undeniable and should be comprehensive, there should be a transition from a fragmented management system to a centralized structure for collecting, processing and storing information. In terms of state and municipal administration, this means applying digital technologies in the provision of public services, increasing digital participation and information transparency, increasing the speed and quality of processing large volumes of data, improving the system of interagency cooperation, as well as the development of the management system of federal, regional and municipal finances of the Russian Federation [1].

Despite the significant development of information technologies in the Russian Federation in recent years, domestic advances still fall far behind the level of developed countries.

2 Methodology

General scientific and special methods have formed the methodological basis of the research, including analysis (content analysis), synthesis, comparison, generalization, analogy. Structural-functional and system methods were used in the research. At a substantiation of conclusions and working out of offers the program-target approach was applied.

The works of leading Russian and foreign academic economists have become a theoretical basis for the research, and the works published in scientific periodicals have supplemented the fundamental provisions with modern approaches and assessments.

The national program "Digital Economy" [2] for the period until 2024 became the basic regulatory document of development of digitalization in Russia, the basis of all digital innovations in state and economic structures. It was developed pursuant to Presidential Decree No.204 approving national goals and strategic objectives for Russia's development until 2024 [3] to ensure accelerated digital development of the economy and social environment.

This program has identified digitalization of data as a key factor in the development of production in all areas of social and economic life. As the main digital technologies in the program were named:

- Big Data technology consisting in processing large amounts of data for visual presentation and analysis;
- neurotechnologies that facilitate brain function and thought processes;
- artificial intelligence technologies that imitate human cognitive functions to automate human activity;
- a distributed registry system (blockchain) that records, stores and updates information on digital transactions and records to ensure data identity for all users;
- quantum technologies including quantum computing, quantum sensors and metrology and quantum communications;
- new production technologies that enable the development of high-tech products;
- industrial Internet, aimed at creating a system of management and remote control over information for corporate and industry applications;
- robotics and sensor technology based on the development of automated systems to process sensory information, interact with humans and replace humans when performing complex and precise work;
- wireless communication, enabling the development of wireless technologies to provide continuous and high-speed access to data;
- virtual and augmented reality technologies.

The "Digital Economy" project defines targets by setting projections up to 2024. The program specifies the costs of digital economy development; infrastructure; share of organizations with access to the Internet; Russia's share in the world turnover of data processing services; number of data processing centers; equipment and software.

The national program also contains federal projects and development directions:

- "Regulation of the Digital Environment". This includes the formation of a legal environment and the introduction of modern digital technologies;
- "Personnel for the Digital Economy". Aimed at improving the educational system to provide the digital economy with specialized personnel, as well as increasing digital literacy of the population;
- "Information Infrastructure". Aimed at providing access to the Internet throughout Russia and creating an related infrastructure;
- "Information Security". It is focused on provision of information environment security and development of domestic technologies of software development and information protection means;
- "Digital Technology". Includes support of domestic research and development of technological products aimed at improving their competitiveness in the world market;
- "Digital Government". It is directed on creation of electronic government and necessary infrastructure for solution of public tasks, organization of public administration in digital sphere.

By the end of 2024, in accordance with the "Digital Government" project, the state should:

- provide operation of the Common Government Services Portal to give users access to a variety of information, including financial information;
- develop and implement unified requirements for data management in the information resources of government bodies;
- ensure electronic interaction between agencies and data compliance (end of 2021);
- establish e-government and its components to ensure that public functions are performed electronically;
- create a digital platform for strategic management and planning at all levels of government (in 2021 the platform should be 100% operational and should be improved by 2024) and other activities.

Quite a large scale of implementation of digitalization in the state budgetary and financial management system is explained by the current administrative and territorial division and the existing management procedure in this area. The introduction of digital technologies into the state budget system ensures:

- a sharp reduction in paperwork and, as a result, lower costs;
- a reduction in time resources and labor;
- reduction of risks associated with the human factor and the automation of multiple data processing processes;
- reliability, openness and availability of information;
- promptness of managerial decision-making by ministries and departments, their coordination and approval;
- increase in the volume of data processed, its storage and analysis capabilities;
- adoption of generally binding rules on processing, analysis and compilation of reports to form a unified information system;
- reduction of corruption offences and other offences related to the financial management system.

3 Results

Since 2010, the Russian Federation has implemented a number of reforms in the budget sphere which were aimed at powers delimitation of federal, regional and municipal authorities; transition to mid-term budget planning; control over targeted use of budget funds; improvement of quality of budget reporting; improvement of efficiency of provision of state and municipal services [4]. As a result of the implementation of the above reforms, the need to create an effective information system of management in the budgetary and financial sphere was identified. Therefore, in 2011 the Federal Treasury introduced the subsystem of budget planning and financial management "Electronic budget", which is still being developed. The given information system allows to essentially reduce paperwork, to raise labor productivity and time of managerial decision-making, to operatively receive the necessary and to carry out financial planning and forecasting from available reliable data more accurately.

The portal of the budget system "Electronic budget" is available at http://budget.gov.ru/. According to the Budget Code of the Russian Federation, the portal "Electronic budget" is a tool for implementing the principle of transparency and openness of the budget system. The purpose of creating the portal was to provide information on the budget system of the Russian Federation, including:

- budget process in the Russian Federation;
- exercising budgetary powers by the Russian Federation, constituent entities of the Russian Federation and municipal entities;
- relations governed by budget legislation;
- information that the Ministry of Finance of the Russian Federation determines in accordance with its budgetary authorities.

The portal "Electronic budget" contains a description of the activities of federal, regional and municipal entities in the management of the budgetary and financial system, including: income; expenditure; balance of budgets; public support; public investment; government programs; public debt; monitoring the quality of financial management of the budget system.

In addition to the open part of the portal intended for citizens and public organizations, there is a special closed part used by organizations of the public administration sector. The closed part of the portal contains functions on database management; statistics collection; budget planning and maintenance of the list of state and municipal works and services; procurement management; accounting and reporting on budget execution; provision of subsidies; maintenance of regulatory and reference information of the Federal Treasury; information security; legal support of documents in electronic form; maintenance of the Consolidated Register, etc.

In addition to the "Electronic budget", Russia also has a number of information systems that provide budgetary and financial management and control:

1. State information system on state and municipal payments—http://roskazna.ru/gis/
   This system stores information on payments between management bodies, payment organizations and citizens. In accordance with Federal Law No.FZ-210 [5] the system has been in operation since 2013 and provides state and municipal services. The Federal Treasury ensures the operation of the system. The system operates on the principle of "single window" and allows participants of the budget system to enter and receive necessary information centrally. It can be noted that not all subjects of the Russian Federation are active in using this portal. Thus, according to the rating of the Federal Treasury website, the most lagging regions are Chukotka Autonomous District, Khakassia, Khabarovsk Krai, Sevastopol (these regions use the functional of the portal by no more than 5%), while the Crimea and Dagestan have indicators 0.02 and 0 respectively.
2. Information and analytical systems of the Federal Treasury
   Their tasks include collection, analysis and visualization of operational data. The information and analytical systems of the Federal Treasury include:

- information and analytical system tracking key performance indicators for the budgets of the constituent entities and other public legal entities of the Russian Federation—http://budget.roskazna.ru/. This system carries out operational analysis of budget execution at the state and municipal levels (detailing is about 24 thousand budgets of individual settlements daily);
- the system of monitoring and analysis of public and municipal procurement—http://contracts.roskazna.ru/. This system analyzes the efficiency of budget expenditures on government and municipal orders;
- data showcases—http://datamarts.roskazna.ru/. Data showcases allow citizens to track data on the state of the budget system and monitor budget management. To simplify understanding of the data presented to the mass user, the system uses a variety of visual and text prompts;
- mobile solution—an application for mobile phones (at the moment the system is developed only on the basis of iOS, the Android application is under development). It contains operational and official information on a wide range of issues on budget execution and planning, including dynamics and comparative data on budgets, structure of revenues, deficit and surplus on federal and consolidated budgets of the subjects of the Russian Federation, etc.

3. The main procurement portal—https://zakupki.gov.ru/
   Procurement portal (Unified Information System in the field of procurement [6]) contains information on the placement of government orders for the purchase of goods, works and services, and also has a mobile version. Despite the fact that the system was created to provide access to complete and reliable information about the contract system in the field of procurement Matveeva [7], in 2016 95% of government procurement was conducted from a single supplier, which was an "imitation of auctions", according to the head of the Federal Antimonopoly Service Igor Artemyev [8]. In 2017 the share of sole suppliers was already 96% [2]. Such purchases are characterized by overpricing, which leads to overspending of budget funds. In addition, the information about purchases worth about 7.5 trillion rubles, or more than 7% of GDP, did not pass through the Unified Information System in 2018 [9]. From 2019, government orders must pass through the procurement system. The monitoring also revealed the unreliability of the portal (21% of the total period of its operation maintenance work was carried out [9]), which negatively affects the development of both government agencies and the business itself.
4. State automated information system "Management"—http://gasu.gov.ru/
   The system "Management" is a unified state information system, which provides collection, recording, processing and analysis of data from federal, regional and municipal levels of government [10]. The system is necessary to eliminate duplication of information flows between state administration bodies. The system "Management" is a component of the central information system. In the budgetary and financial sphere, the system "Management" is used to monitor, analyze and control processes that take place in the country's economy.

5. The official site for placing information about state (municipal) institutions—bus.gov.ru
   The portal accumulates information on state and municipal institutions and services provided by them, including information on subsidies allocated and their distribution.
6. Federal Treasury Certification Center
   The Centre provides participants of the budget system and other state management systems with electronic signature verification key certificates, which improves the security of electronic document circulation.
7. Remote Financial Document Management System
   The service is a web application that allows you to work quickly with financial data, documents and reports.

It is worth noting a number of shortcomings identified as a result of the analysis of functioning information systems. Firstly, practice has shown that there is no clear structure of digital solutions within departments, between them and along the vertical power lines. Secondly, there is a fragmented application of digital technologies in administrative processes. Thirdly, there is a high level of complexity in the use of digital technologies because the methodological guidelines for their use are written in "technical" language and do not take into account the existing level of qualification of personnel in the use of these products. Fourthly, such systems as Information and analytical systems of the Federal Treasury collect information, i.e. they operate "from the bottom up", but an integral system that coordinates and makes data publicly available to all levels and institutions has not been created at the moment. Finally, the main problem of the existing system is the significant number of participants in the budget process and large volumes of data, which complicates the development of the digital state in the current high-tech economic environment.

4 Conclusion

The analysis showed that digitalization is directly related to the financial sector of the economy. At the state and municipal level of management, finance implies various material flows and a number of certain financial relations. In combination with the sphere of financial relations, digitalization is an economic system based on generation, processing, storage and transmission of data; advanced digital and information technologies required for financial forecasting and planning, monitoring and control by the constituent entities of the Russian Federation.

More than twenty years of history of the use of the Internet and digital technologies in the activities of federal, regional and municipal governments, but its development today is still far from ideal. The topical problems of the development of digitalization and informatization of the budgetary and financial systems in the Russian Federation should be attributed to:

- imperfection of the legal and regulatory framework in this area (despite the adopted projects and strategies, budget legislation does not adequately regulate the areas and ways of application of digital technologies);
- lack of highly qualified personnel (including low information education among civil servants) and scientific technological developments;
- lack of budget financing;
- inefficient inter-department cooperation.

As a consequence, there is a low availability of necessary equipment for state administration bodies, especially in the regions. Many agencies still continue to operate mainly on paper, using seals and signatures, increasing processing time and generating bureaucratic delays. At the same time, budget legislation in Russia is undergoing frequent changes; accordingly, new tasks are emerging at all levels of public management, which cannot be solved without the use of digital technologies [11].

It is also worth noting a number of shortcomings identified through the analysis of functioning information systems. Firstly, practice has shown that there is no clear structure of digital solutions within departments, between them and along the vertical power lines. Secondly, there is a fragmented application of digital technologies in administrative processes. Thirdly, the problem lies in the high level of complexity of the use of digital technology, because the methodological guidelines for use are written in "technical" language and do not take into account the existing level of qualification of personnel in the use of these products. Fourthly, such systems as Information and analytical systems of the Federal Treasury collect information, i.e. they operate "from the bottom up", but there is no complete system that coordinates and makes data publicly available for all levels and institutions at the moment. Finally, the main problem of the existing system is the significant number of participants in the budget process and large amounts of data, which complicates the development of the digital state in the current environment of high-tech economic development.

Digital Platforms as a Business Engine in Smart Space

Valentina V. Poliakova, Sona L. Sumbatyan, and Ester A. Hakobyan

Abstract The article deals with digital platforms as a phenomenon that emerged at the turn of the century in the conditions of digital transformation. With the help of digital technologies in all sectors of the economy there is a transition to a new format of relationships. The appearance of digital platforms expands the opportunities for cooperation, increases the productivity of business processes, accelerates the interaction between different subjects of ecosystems, erasing borders and time zones, transforms the structure of traditional markets in the smart space. The purpose of the study is to define the concept of a digital platform, as well as the peculiarities of the formation of international and national platform solutions. Definitions of digital platform, platform business model, platform ecosystem are given. Classification features of digital platforms are considered. The strategic analysis of digital platforms activity is carried out, experience of foreign and national platform business models is considered. An overview of key ecosystem indicators implementing digital platforms is provided. Segmentally large Russian digital platforms have the potential to enter the global digital market and offer competitive digital solutions in the near future. In order to strengthen Russia's position in the global digital space, the government needs to take effective measures to support the development of digital technologies and address the global problem of confidentiality of personal data collected and processed by the platforms.

1 Introduction

With the digital transformation of economic principles of society, global trends in the popularization of digital devices, universal accessibility of mobile Internet, there is a continuous development of various digital technologies. The future of ecosystems is shaped today by the introduction of artificial intelligence, the Internet of things, blockchain, Big Data and other information technologies. The unique features of digital platforms as a tool for the digitalization process allow to transform traditional business into platform business models. Platform solutions in the form of new disruptive innovations create the prerequisites for the transition to the smart space, providing the relationship among customers, partners, software developers and applications.

Transformation of the traditional business model into a platform model allows to achieve sustainable market growth and increase business competitiveness.

Digital platforms are developing in parallel with the ongoing global digital transformation of society. Initially, the creation of a communication platform for participants in a certain market segment, the availability of its basic services allows to start the process of optimizing transactions and expenses of its users. Manufacturers get access to a conventionally free way to attract consumers through multi-channel marketing (Facebook, Instagram, Telegram, etc.), but the platform is not seen as a competitor or a threat to business and it is easily admitted into its added value creation process. The margin of the business is constantly growing, due to the absence of intermediaries, the growth of active members of the network, and the gradual transfer of all participants to the platform model.

With all the positive effects for smart space participants, digital platforms carry serious risks and threats to society: possession of confidential personal information, monopoly on digital infrastructure, manipulation of platform participants. Ultimately, platform owners begin to control the market and influence the business environment not only at the industry level, but also at the level of governments.

2 Methodology

At the moment there is no unified methodological approach to defining digital platforms in the scientific community, but the research interest of different scientific schools and concepts is focused on identifying the essential characteristics of platform architecture, approaches to their classification, management, competition and many other problems.

The purpose of this study is to determine the role and place of digital platforms in the global smart space, identifying the features and prospects of national and global platform solutions.

In the process of the study methods of system analysis, comparison, description, generalization, systematization, formalization and SWOT-analysis and other methods of scientific research were used.

3 Results

In the information technology system, the term "platform" means a complex (hardware or software) that serves as a basis for the development of computer systems. In the conditions of digitalization, the digital platform is understood as a business model of digital business, built on a wide involvement of participants and users.

The business built on a digital platform creates value through external resources of digital partners and user communities. Based on the experience of DBO companies (digital-born organizations), the market capitalization of businesses operating in the digital ecosystem is about 3 trillion dollars [1].

Having considered the principles of doing business in a traditional format and taking into account the specifics of digital platforms, we can highlight the characteristic transitions of the traditional model to the digital one:

Firstly, the inherent linear value addition that reflects the supply chain in the digital ecosystem is transformed into a non-linear format;
Secondly, in the traditional model, control is concentrated in the supply chain, and digital format allows control of the entire ecosystem;
Thirdly, with the implementation of the digital platform, economies of scale are shifting from supply to demand, and value is growing with more consumers than suppliers;
Fourthly, the digital model delivers impact as the network effect of the digital ecosystem develops [2].

Digital platform as any product goes through the life cycle of formation and development.

Figure 1 shows 3 phases of the digital platform life cycle, the transition to the next stage depends on the number of users, which is a direct factor of platform capitalization growth.

Digital platform users are suppliers, asset owners and consumers. Digital platforms have different forms of user interaction reflecting the relationship of needs to resources: people-to-people, people-to-machines, machines-to-machines. The digital platform includes the technology design, the platform business model and the ecosystem created [3].

The technological design of the digital platform, as opposed to classical traders and intermediaries, has no direct interaction between the parties and vertical integration of the companies of one party. Examples of such business models are platform solutions for sharing different assets: sharing platforms, peer-to-peer platforms [4].

The platform ecosystem is formed by the communities of different participants in the digital platform, the value created by interaction and competition on the platform,

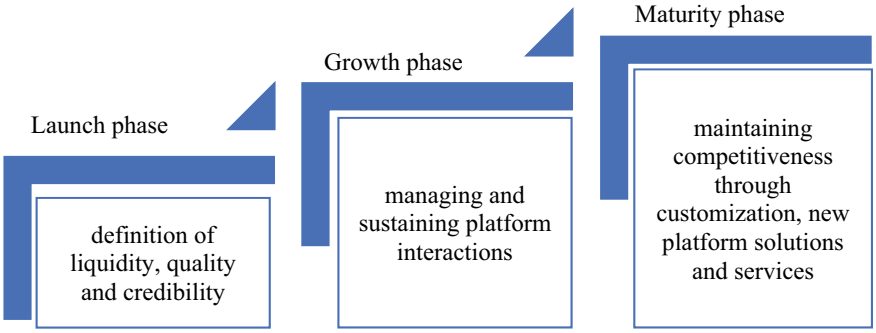

Fig. 1 Digital platform life cycle

and the system of relationships. The functioning of the platform ecosystem uses not only self-governance mechanisms, but also management mechanisms aimed at ensuring the necessary level of control and motivation of participants.

Within the smart space there are three main models of digital platforms: decentralized, centralized and hybrid. The main criteria for this classification are asset ownership and pricing [5].

In the decentralized model, the owners (suppliers) of an asset offer it directly to the user on their terms, while the digital platform connects agents and facilitates their transactions for a small fee. Start-up capital investments are low because the platform must guarantee to attract suppliers to maintain an optimum supply level. An example of a decentralized model is the digital platform AirBnB and other accommodation booking systems.

In a centralized model, asset ownership and pricing are the functions of the platform. The digital platform of this model receives a significant share of the transaction cost for quality control and standardization, but also the cost of scaling increases, which in turn affects the amount of advanced capital. The use of a centralized model provides a higher level of efficiency in the use of the digital platform, as shown by the example of Zipcar, Rent the Runway.

In a hybrid model, the digital platform sets the prices and standards at which asset owners offer their service. Decentralization is about ownership and risk, while centralization is about standardization and service levels. The similarities with the decentralized model are low initial costs and the critical importance of suppliers, while the similarities with the centralized model are high levels of control. A successful example of a hybrid model is the Uber digital platform.

In the global smart space, all digital platforms can be divided in scale: global (PayPall, Facebook, Instagram, Telegram), regional (Yandex, VKontakte, GLONASS) and national (Qiwi).

There is no uniform classification of digital platforms in international practice. According to the researchers of The Center for Global Enterprise, the classification criterion is the functionality of the platform, based on which four groups are distinguished: operational, innovative, integrated and investment.

Deloitte University experts similarly divide digital platforms by functionality, but the groups they have formed are different from the interpretation of The Center for Global Enterprise: aggregated, social, mobilization and training platforms [6].

To date, Russia has adopted a national program "Digital Economy of the Russian Federation", whose participants classify digital platforms into three types: instrumental, infrastructure and applied [7].

Instrumental digital platforms are realized in the sphere of software solutions development, the final product of which is a tool—a product for information processing. The processing of the information accumulated on the platform is only at the level of technological operations. On this platform the key participant is the developer of application software or software-hardware solutions, setting technical requirements to other participants of the platform. The instrumental platforms include such digital platforms as Java, Android OS, iOS, Intel x86, Amazon Web Services and others.

Digital platforms involved in decision-making through the provision of IT services and information are referred to as infrastructure type. The IT service owner sets functional requirements for the platform users in terms of the composition of the information that is subsequently processed. The result of the platform's operation is the information necessary for the user to make decisions. Digital platforms GE Predix, ESRI ArcGIS, CoBrain-Analytics, ERA-GLONASS, etc. can be regarded as infrastructure platforms.

The applied digital platform serves as a platform for the exchange of certain economic values in the established markets, which results in a transaction between the platform participants. The information processed on the platform includes data on conclusion and execution of a transaction among several participants. This platform solves the business tasks of the end-user. Digital application platforms include Uber, AirBnB, Aliexpress, Booking.com, Avito, Apple AppStore, Aviasales, Facebook, Alibaba, etc.

The approaches considered to classifying digital platforms are rather general in nature, since assigning a particular platform to one type or another faces the difficulty of defining its essence and performing simultaneously many tasks in the smart space.

One of the criteria for grouping digital platforms can be the basic business model. Table 1 shows the types of digital platforms with an indication of the business model.

The business constructed on the platform solution, has a number of advantages, the main of which consists in reduction of transactional, operational, time and other expenses for business. On the example of the passenger transportation market, according to the results of PricewaterhouseCoopers, about 60% of passenger transportation users choose the digital platform (Uber, Lyft, Zipcar, etc.) because of the best price, wide choice and convenience of services [4].

Digital platforms provide businesses with access to global markets and participation in value chains. Examples include placing a mobile app on App Store or Google Play or offering products and services on Amazon, eBay.

Digital platforms can serve not only as a platform for large and medium-sized companies, but also as a catalyst for individual forms of business by reducing entry

Table 1 Business models for digital platforms

Business model	Digital platform type
Advertising	Search platforms Social platforms Knowledge platforms
Percentage from sales/posting fee/user identity trading	App stores Marketplace
Subscription	Media-platforms
Revenue in action (payment for clicks or registrations)	Partner platforms
Payment as consumption grows	Crowdsourcing platforms Infrastructure platforms

barriers. According to the results of the digital platform Etsy, about 45% of its participants first engaged in individual trading due to the created digital conditions [8].

Consumers of digital platforms recognize the advantage of online commerce over the traditional form by accessing a wider range of goods and services, and by reducing prices while reducing suppliers' overheads.

The platform business model allows using the digital platform's access resource to personal data of potential customers to individualize interaction with them.

With all its obvious advantages, digital platforms are associated with risks and threats.

The essential and primary problem is the threat of violation of confidentiality of personal data, as digital platforms accumulate and process large amounts of data about participants and their actions. Unscrupulous use of personal information can be dictated by unfair competition, manipulation of participants, markets and even states.

In terms of legislation, there is currently a lack of clarity and flexibility at the international and national levels in the regulation of both digital platforms and business based on the platform model, which is reflected in the ambiguity of court decisions in case of violations of laws. The problem of securing transactions is not the last one in the real smart space.

Platform profits are often maximized by applying a predatory pricing strategy to consumers as well as overcharging suppliers. Supplier activities are accompanied by the risk of revenue instability if the digital platform sets tariffs that are highly volatile. Suppliers also have to bear the cost of compliance with the platform's quality requirements and capital costs from their own sources.

Touching upon the remuneration aspect of the digital platform participants, they do not have rights, benefits or other social preferences because they do not act as full-time employees but are involved in the digital platform as independent performers [9].

When analyzing the global smart space, it is obvious that the platform business model is becoming a mass phenomenon. The number of platform companies has

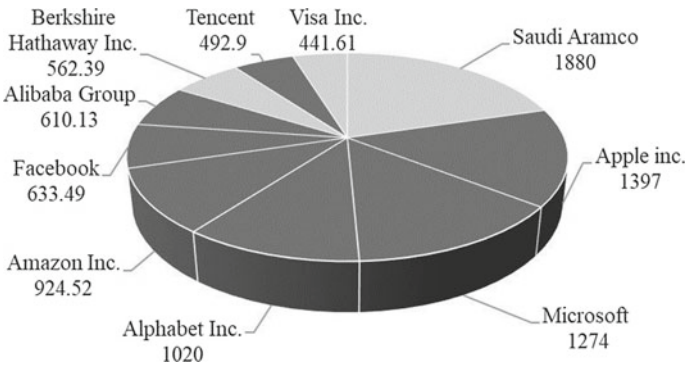

Fig. 2 Top 10 largest companies in the world with capitalization, billion dollars

changed dramatically over the past ten years. While in 2008 the list of the most capitalized companies in the world included only one Microsoft platform company, as of January 2020, 70% belong to platform companies (Fig. 2).

The platform companies represented are mainly based in the USA and China. The rapid growth of the presented platform companies is due to the increase in the size of smart space due to the increasing number of active Internet users [10].

In Russia, the distribution of digital platforms is observed in the format of social networks, messengers, search engines, marketplaces, tourism, passenger transportation, etc. In terms of capitalization, national digital platforms are significantly inferior to the raw materials and banking sectors of the Russian economy. According to the results of 2019, the Top 100 includes only two platform companies (Yandex, Mail.Ru Group), whose market capitalization is at the level of 14 and 5 billion dollars respectively [11].

In order to create favorable conditions for the development of digital platforms and digitalization of the Russian economy, the Russian Government is taking significant measures, in particular, a national project for the establishment of a digital economy, as well as measures to develop domestic digital platforms are reflected as one of the strategic objectives until 2024.

The digital platform is the engine of business growth, which has already passed the stage of automation and informatization and is on the verge of digital transformation. The main reason for the transition to digital platform format is the reduction of business costs and the ability to optimize management in the emerging smart space.

The basic technologies of the past stages of economic transformation are replaced by application solutions in the format of digital platforms, which accumulate a large number of users and business partners, forming entire ecosystems.

4 Conclusions

In the global context of digitalization of the economy, countries should not allow digital monopolization, as the introduction of digital platforms provides the preconditions for the previously unknown model of control of the digital segment of traditional business. Receiving digital benefits from the use of platforms at the moment, ecosystem actors take great strategic risks, losing control over operations and becoming dependent on the owners of digital platforms.

While supporting the model of digital transformation in different economic sectors, it is important to maintain an optimal balance between protection of national security and consumer interests, as well as to ensure that digital platforms penetrate all elements of the smart space.

Evaluation of the Effectiveness of the Implementation of Digital Public Procurement Systems: European Experience

Olga M. Pisareva and Svetlana A. Suyazova

Abstract *The aim* of the work is to study international, mostly European, experience in implementing tools and technologies of electronic public procurement in the sphere of public administration. In particular, the authors postulated the hypothesis that the trading volumes within the framework of the most efficient European electronic public procurement systems are directly related to the quality metrics of electronic systems. *The methodology* of the study is based on a systematic approach to the study of cyber-economic systems and processes using semantic, logical, statistical, content, expert, comparative and exploration analysis, as well as econometric modeling methods. In the course of the research the following scientific results were obtained: the accumulated international experience in the field of informatization, automation and digitalization of public procurement processes was analyzed; representative statistical material on the volumes, costs and conditions of public procurement on the European trading platforms was collected; pre-processing of statistical material on both the characteristics of procurement and on the metrics of public trading platforms was carried out; specification of econometric models was carried out; an econometrical model was built; and an econometrical model was constructed. The study allows us to conclude that at present there is a global trend of increasing volumes of public procurement, including those sold through special digital trading platforms; the experience of the European Union confirms the hypothesis that there is a significant identifiable relationship between the volume of trade and the fixed quality metrics of digital trading platforms—with the growth of quality parameters of technologies and mechanisms of public procurement there is an increase in successful transactions and their cost.

1 Introduction

The national project "National Program "Digital Economy of the Russian Federation",[1] which is currently being implemented in the Russian Federation, involves large-scale implementation of strategic initiatives of the state in the field of radical modernization of the information and communication sector of the country, as well as building a developed information society. This is being directly embodied by means of support for the six federal projects included in the program, and also through very substantial funding. According to the passport of the national program, the amount of its financing is to exceed 1.627 trillion rubles between 2019 and 2024. Figure 1 illustrates the planned dynamics of financing of the program components by years of its implementation. The structure of sources of funding for the program and their annual volumes are shown in Fig. 2. At the same time, it is important to note that the investment dynamics provided for in the program passport will require an additional 24% of federal budget expenditures as early as in 2020, which is about 29.7 billion rubles in value terms, and in 2022–2024 this share will increase to 91% (estimated at 234.8 billion rubles).

In this regard, the Government of the Russian Federation is currently working actively to encourage the involvement of very significant amounts of non-governmental funding in the implementation of federal projects under the national

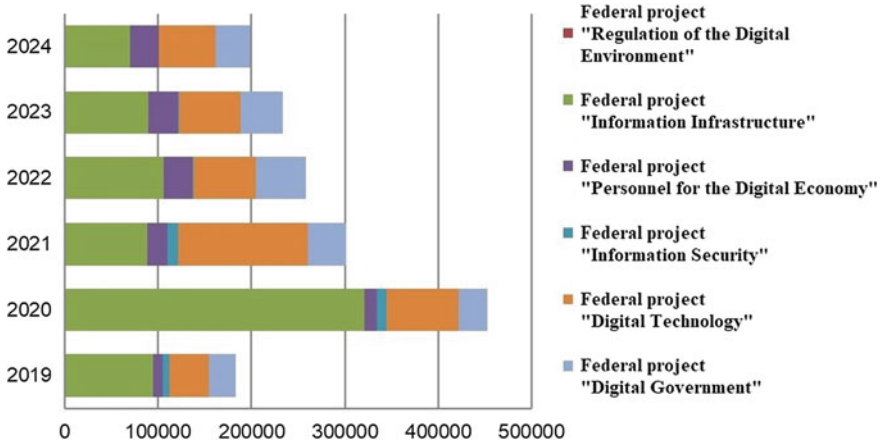

Fig. 1 Financing of federal projects of the national program "digital economy" (million rubles). *Source* Compiled by the authors based on the data [20]

[1] National Project Passport was approved by the Presidium of the Presidential Council for Strategic Development and National Projects, Protocol No. 7 of 04.06.2019. URL: http://www.consultant.ru/document/cons_doc_LAW_328854. Accessed 07 Feb 2020.

	2019	2020	2021	2022	2023	2024	Total
extrabudgetary sources	75 388,00	328 646,68	123 478,75	0	0	0	527 513,43
consolidated budgets of the constituent entities of the Russian Federation	0	150	150	0	0	0	300
federal budget	108 048,51	123 656,66	177 898,86	258 015,00	233 394,00	198 570,00	1 099 583,

program. Their amount is comparable to the volume of state financing and is estimated at up to 1.5 trillion rubles.[2]

In the conditions of limited resources and strict limits on their targeted use, it is necessary to develop and integrate into the sphere of digital interaction between government agencies already functioning digital platforms for interaction between government agencies and economic agents. This is particularly true of public procurement mechanisms, where the requirements of transparency in bidding procedures, clear identification of parties and compliance with regulations are well suited to the opportunities offered by modern information and communication technologies and, in particular, digital management technologies.

Today, there are some digital platforms operating at the federal level in Russia, for example: Unified Information System (UIS) for public procurement zakupki.gov.ru and six electronic trading platforms:[3] Sberbank-AST (Savings Bank of Russia Electronic Platform), www.sberbank-ast.ru; National Electronic Platform, www.etp-ets.ru; RTS-tender, rts-tender.ru; State Unitary Enterprise "Agency for State Order, Investment Activities and Interregional Relations of the Republic of Tatarstan", www.zakazrf.ru; JSC "United Electronic Trading Platform", www.roseltorg.ru; Electronic Trading System of JSC "Russian Auction House", lot-online.ru.

According to the State Statistics Service of the Russian Federation,[4] the volume of government procurement in our country is currently about 5–6% of the total GDP of the country (3% in 2017, about 7% in 2018). This is noticeably lower than in OECD countries, as can be seen from the data presented in Table 1.

Table 1 Volumes of public procurement in % of GDP by OECD countries in 2017–2018

Value group	Procurement volume, % of GDP	Number of countries, 2017	Number of countries, 2018
Upper values	over 16%	5	4
Median interval	10–16%	24	17
Lower values	less than 10%	9	5
Total countries participating in the OECD ranking		38	26

Source Compiled by the authors based on the data [15]

Most countries in the world are currently undertaking reforms related to the online procurement process. According to the World Bank [1], at the beginning of the twenties, only 26 of 180 countries do not have an e-procurement portal for public procurement, and therefore there is now considerable experience in digitalizing this activity.

In this regard, the aim of the work performed was to study international experience in the implementation of tools and technologies for electronic public procurement (hereinafter—public procurement) in the field of public administration. In particular, the authors postulated a hypothesis that the auction volumes within the most efficient European electronic public procurement systems are directly related to the quality metrics of electronic systems.

The authors solved the following *set of research problems*: the analysis of the accumulated organizational and technological experience in the field of informatization, automation and digitalization of public procurement processes abroad, as well as the study of statistical material on the physical and value volumes and conditions of trading on such sites; formation and processing of statistical material on both trading volumes and quality characteristics, i.e. metrics (hereinafter referred to as practice, attribute) of the state trading platforms themselves, as well as specification of initial econometric models; evaluation of dependence of trading volumes on attributes of the trading system and validation of empirical probability models on available statistical material; formation of conclusion on the conducted research.

The information sources of the research were open databases, analytical and regulatory information of relevant domestic and international organizations, public administration authorities of individual countries, in particular—Organization for Economic Co-operation and Development (http://www.oecd.org), International Bank for Reconstruction and Development (http://www.siteresources.worldbank.org), European Commission (http://ec.europa.eu), Tenders Electronic Daily (TED, https://simap.ted.europa.eu/en), Rosstat (http://www.gks.ru) and scientific and practical publications of Russian and foreign scientists.

In general, the study is based on a systematic approach to cyber-economic systems and processes using methods of semantic, logical, statistical, content, expert, comparative and exploration analysis, as well as econometric modeling.

2 Methodology and Background

The methodological basis for the research was the scientific and practical works of domestic and foreign scientists, experts and specialists in the field of public administration, contracting and strategic development of information systems and technologies, modeling processes and systems. The issues of organizational, methodological and technological support of procurement and contracting processes in the state and public administration are discussed in the works [2–6]. The problem of forming a methodology and tools to assess the effectiveness and efficiency of the design, implementation and operation of cyber systems in the field of public administration, including the use of statistical and econometric modeling methods is elaborated in the following papers [7–11]. The results of empirical analysis of electronic systems in procurement can be found in works [5, 6, 12–14], as well as in analytical reports and reviews of relevant organizations [1, 15–19].

3 Results of the Research

The study of the material available to the authors, related to the reports on the specifics and results and the functioning of platform solutions in the field of public procurement support [1, 15–17, 19], allows us to conclude that the e-procurement process in the public sector has its own specifics, which distinguishes it from the introduction of information technologies in business processes. First of all, this is the scale of cooperation: many regional players can take part in public procurement competitions at one time. In addition, domestic and foreign sources highlight a group of key factors that come to the fore in public procurement [3, 6]. For them, the following is essential:

- interaction of citizens, business and government representatives in managing the process through common regulatory, technological and procedural standards;
- user orientation, identification and involvement of key actors in the process;
- automated procurement data analysis to monitor targeted use of funds, assess key performance indicators and provide feedback for the purpose of reengineering bidding procedures;
- increased decision-making speed, freeing up time for key tasks and quality communication with responsible employees through automation of routine activities.

In order to effectively implement these factors, it is necessary not only to improve the technical base, but also to take into account the already accumulated best practices

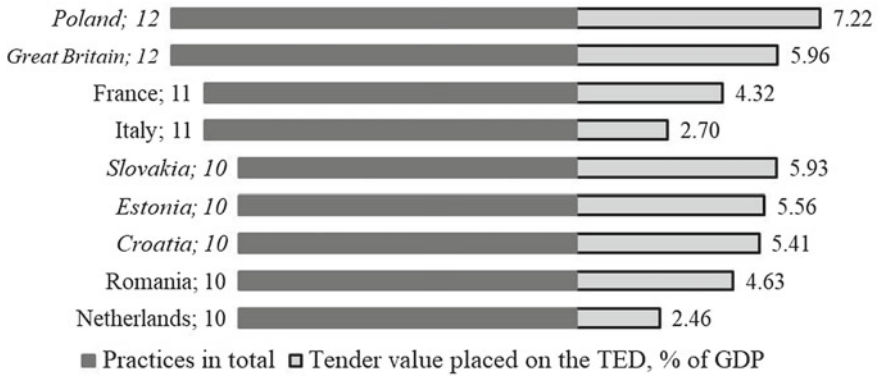

Fig. 3 Top 9 countries by number of best practices applied. *Source* Compiled by the authors based on the data [16, 17]

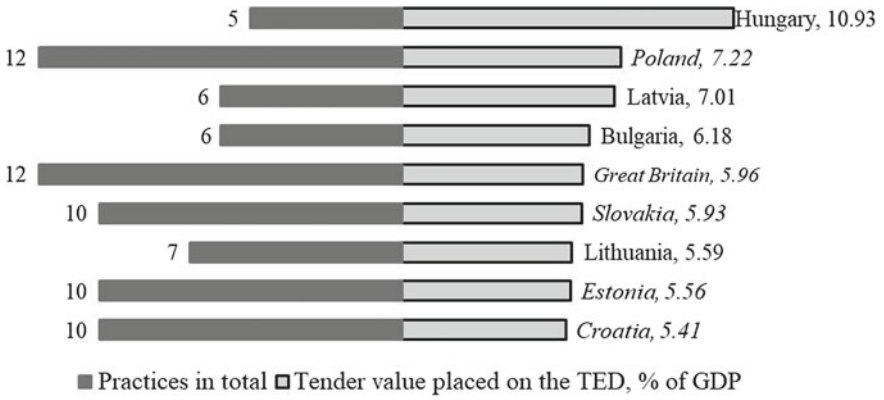

Fig. 4 Top 9 countries by TED tender costs. *Source* Compiled by the authors based on the data [16, 17]

in the field of organization and maintenance of the public procurement process, and the addition of new tools and practices should be accompanied by an understanding of the expediency of their use by all parties involved.

Descriptive, correlated and causal analysis of the EU public procurement statistics showed that there is no significant direct correlation between the number of the best practices of public procurement (in the official recommendations of the EU Commission there are up to 30 names of them [1, 16, 17] and the volume of trades. However, it is quite obvious that the leading countries in the field of system efficiency evaluation (Fig. 3) are also leading in terms of the cost of placed bids on the TED electronic platform[5] (Fig. 4).

[5]Tenders Electronic Daily (TED)—an electronic version of the European public procurement journal "Supplement to the Official Journal", where all active applications are published.

Table 2 Characteristics of the models of dependence of the logarithm of total contract cost in billion euros (Y) on the number of efficiency metrics (X) for the EU countries

No.	Range of contract value, million euros	Model (standard parameter errors are shown in brackets)	Number of observations	R^2_{adj}	$A(\%)$
1	(0 5.225)	$Y = -1.460 + 0.085X$ (0.31) (0.04)	28	0.119	52.3
2	[5.225 25)	$Y = -1.432 + 0.143X$ (0.25) (0.03)	28	0.413	99.8
3	[25 100)	$Y = -1.382 + 0.118X$ (0.35) (0.04)	25	0.210	92.6
4	[100 max]	$Y = -0.983 + 0.099X$ (0.48) (0.05)	18	0.119	237.1

Source Compiled by the authors based on the data [17]

Given the overall complexity of the procurement system and its specificity to each country, we can assume that the key role in it should be played not by the number of formally defined positively identifiable quality metrics ("practices") of public procurement, but by their integral efficiency and awareness of application.

In this sense, an interesting picture is given by comparing the number of best practices and the distribution of procurement by contract cost. Initially measured on the original statistical material, the relationship between them is not linear. However, presentation of the total value of procurement in form of a logarithm allows to reveal positive linear relationships between them. The corresponding correlation coefficients become significant with a confidence level of 0.95. Table 2 shows the characteristics of relationship models (here R^2_{adj} is a corrected determination coefficient, A is an average approximation error of the model).

An example of graphical representation of the model 2 from Table 2 is illustrated in Fig. 5.

Thus, the strongest number of best practices in Europe increases the share of government contracts for works of average value, costing from 5.255 to 25 million euros and to a slightly lesser extent—from 25 to 100 million. This may indicate an increase in trust between participants in the procurement process.

Testing the properties of the models presented in Table 2 showed that they do not have predictive value because the approximation quality indicators are low: the corrected determination coefficient did not exceed 42%, and the average approximation error shows that the average absolute model error exceeds the average value of the dependent variable by 50–240%. However, the regression coefficients were significant with the probability of 0.95. This allows interpretation of the relationship between the variables. The strongest number of best practices in Europe increases the share of government contracts for works with an average value of 5.255–25 million euros and, to a slightly lesser extent, 25–100 million euros. This may indicate an

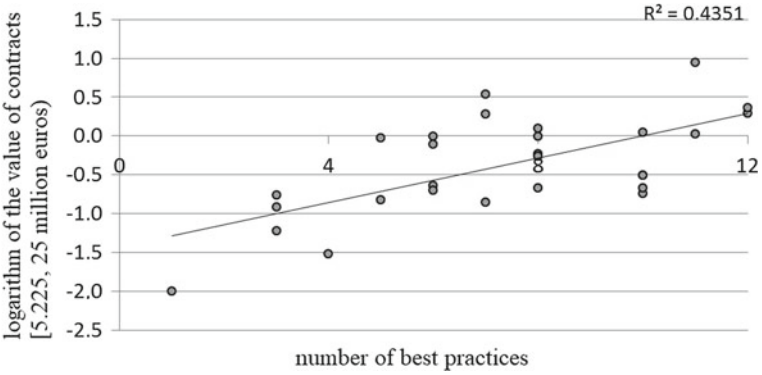

Fig. 5 Illustration of a noticeable positive correlation between the number of best practices and the logarithm of the total value of contracts (range 5.225–25 million euros). *Source* Compiled by the authors based on the data [17]

increase in trust between the participants in the procurement process as the number of best practices increases.

Positive relationships can also be seen between the number of best practices applied and the number of work contracts awarded (Table 3). However, the dependent variable still has more variance than the model can explain, so the average approximation error is high. An example of graphical representation of the model 2 from Table 3 is illustrated in Fig. 6.

The 2017 model for applications below 5.225 million is insignificant; in other groups, the relationship between the number of best practices and the number of contracts is slightly more marked than the total value of contracts. The latter indicates

Table 3 Characteristics of models of dependence of logarithm of number of contracts (Y) on number of best performance metrics (X) for the EU countries

No.	Range of contract value, million euros	Model (standard parameter errors are shown in brackets)	Number of observations	R^2_{adj}	A (%)
1	(0 5.225)	$Y = 1.433 + 0.079X$ (0.38) (0.05)	28	0.056	26.8
2	[5.225 25)	$Y = 0.577 + 0.142X$ (0.25) (0.03)	28	0.415	22.6
3	[25 100)	$Y = 0.017 + 0.115X$ (0.32) (0.04)	25	0.217	48.1
4	[100 max)	$Y = -0.342 + 0.097X$ (0.36) (0.04)	18	0.209	59.6

Source Compiled by the authors based on the data [17]

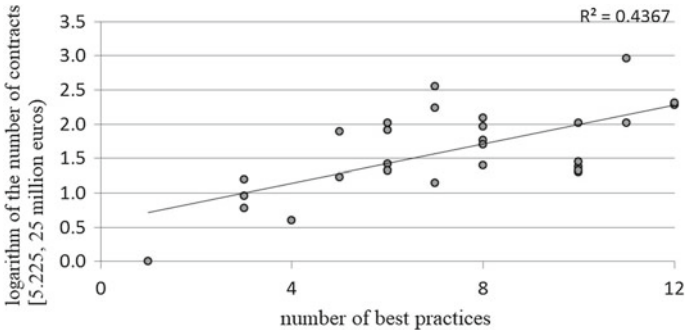

Fig. 6 Illustration of a noticeable positive correlation between the number of best practices and the logarithm of government contracts (range from 5.225 to 25 million euros). *Source* Compiled by the authors based on the data [17]

that the growth in the number of good practices in public procurement systems as a whole contributes to the scaling of the public procurement system and stimulates the growth of contract volumes at the respective site.

4 Conclusions and Further Research Directions

Thus, the study conducted by the authors allows us to draw the following conclusions:

- currently, there is a worldwide trend of increasing volumes of public procurement, including through special digital trading platforms;
- empirically (on the material of the European Union countries) the hypothesis is confirmed that there is a significant identifiable dependence between the trading volumes (physical and value) on specialized electronic trading platforms and fixed quality metrics of digital trading platforms—with the growth of quality parameters of public procurement technologies there is an increase in successful transactions and their volumes;
- most effective practices include the establishment (improvement) of a system for collecting and storing procurement data, and the need for procurement data to be presented, pre-processed and offloaded in generally accepted standards.

The possibility to scale up the best experience of building public procurement systems in the European Union countries will allow us to correctly identify the probable gaps and identify promising directions for the development of such systems in our country. The latter will undoubtedly help justify the decisions on adaptation and development of the electronic procurement system in Russia, successfully transferring it into a fully functional and integrated digital platform format.

Digitalization as a Driver of the Banking Sector

Elena B. Starodubtseva, Marina V. Grachyova, and Marina B. Trachenko

Abstract This article is dedicated to the review of the main changes occurring in the banking sector after digitalization. The analysis of principal introductions of modern technologies in banking allowed us to conclude that banks should thoroughly work out a strategy of further development in view of changing trends and digitalization in all areas of their activities. We showed that digitalization acts as a driver for the development of the bank as a financial supermarket, which not only provides traditional banking services but also establishes its own ecosystem and can enlarge its client base. As a result, the competitiveness and stability of the banking system are growing. It is pointed that digitalization also has negative implications, especially nowadays, such as higher bank's expenses for the introduction of technologies, staff training, data protection, the release of labor, which may negatively affect employment in the country.

1 Introduction

In recent years the volume of economic digitalization is increasingly growing. This is especially exhibited in the financial and, foremost, the banking sector. This fact is proved by that up to 75% of all banking operations in Europe and the USA are effected via the Internet, smartphone, or ATM [1]. Russia is not far behind the leading countries, but the further development of the economy requires from banks a more serious approach, as far as practice shows that new technologies and digitalization in particular act as an additional impetus. Banks practicing digitalization have managed to cement their positions, attract customers, and secure market stability [2, 3].

2 Methodology

The study has relied on idealization and formalization, historical and logical, experimental methods of research, observation, simulation, abstraction, comparison.

It is worth noting that digitalization has been of the highest attention in recent years. However, there are some questions not only related to the definition of digitalization but also its impact on the development of both the banking sector and the economy. Speaking about the term of digitalization, we should mark that some authors regard it only as Internetization of society as a whole, others suppose that digitalization is the introduction of the latest technologies in the companies [4], and sometimes it is propounded to interpret digitalization in both narrow and broad terms [5]. In view of covering this topic, we will fall back on the definition of digitalization as the introduction of the latest Internet technologies in the banking sector. The second side of this issue is the impact on the banking sector and implications of the introduction both for the banking system and economy as a whole. In the first point, the authors are unanimous in their estimated, noting that the banking system will dramatically change (under this influence, we see the first positive changes) [6], but on the other hand, they indicate less time for banking operations, cost reduction, the emergence of a new type of the bank (digital bank) as pros, and fraud, higher security costs, the release of employees as cons [7].

3 Findings

Presently, Internetization covers most of bank customers. As of the beginning of 2020, the number of Internet users in the world exceeded 4.5 billion people, which is almost 60% of the world's population.

Russia with 109.5 million Internet users is the eighth by their number among the largest countries of the world. The number of mobile users is even higher (5.11

billion people), which is 67% of the world's population, while smartphones account for two-thirds of mobile phones (5.5 billion).

The Internet is the most widely used in developed countries (81%), while its share in developing countries is 40%, and in ones with a transitional economy is 15%. However, despite that our country belongs to the transitional type, the percent of Internet coverage is pretty high [8].

All this leads to the need and opportunity of using this phenomenon for expansion of the services that could be provided to customers on-line with the help of modern digital technologies. This especially concerns payments and settlements. According to statistics, in recent years, cashless payments in Russia have drastically increased not due to the unconventional way of money transfer from one account to another, but through the active issue of cards. Ease of payment has become an undeniable advantage of credit cards, which number hit over 14 billion by the end of 2019. The global coverage of smartphones (especially in large cities) has led to the emergence of an additional option such as smartphone payment, which has even more facilitated payment. The electronic payments among customers found to be more popular than Internet banking (31%) and SMS payments (37%) [9].

To the greatest extent, digital technologies of the banking sector are exhibited in interbank electronic settlements and payments. For example, a widely-known SWIFT system, which unites 9,000 credit organizations from 200 countries of the world effects more than 2.5 billion payments annually. Through the federal automated money transfer system Fedwire developed for real-time gross settlements, 99% of all payments by US credit institutions are made. TARGET-2 system widespread in the EU carries out payments between credit organizations of the EU countries [1].

As the economy develops, it becomes harder for banks to gain high profits within conventional operations (deposits, granting loans). Interest on deposits due to deflation in developed countries tends to zero, which constricts cash inflow to banks. The securities market here is an obvious alternative to the employment of funds, but the investment risk is multiple. Bearing in mind that the bank activities depend heavily on attracted funds, as this allows them to effect asset-related operations, it is digitalization that can help banks in raising funds and correlate time costs with monetary incomes. In this event, banks start developing on-line platforms for maintaining customer accounts and opening deposits, setting mobile banks, digital banking, or e-banking. Using electronic banking, commercial banks provide their clients with services on issuing statements of transactions, making intra-bank settlements and account transfers, as well as interbank transfers in settlement transactions. Moreover, they furnish information to customers on the types and provision terms of banking services, such as deposits, loans, shares of investment funds, etc., accept and handle applications for opening a deposit, granting a loan, issuing bank cards, convert currency, etc. In past years, this type of bank's activity has become more widespread, as evidenced by indicators of digitalization state in the country. An example of the ubiquitous distribution of such a service is China with 97.5% of mobile bank users. Eighty-six out of the 100 largest banks in the United States provide Internet services.

In the EU, half of the population practice intensive use of mobile banking for settlements and other banking services, but this is an average figure, since in some

countries, for example, Norway, this indicator reaches 90% [10]. Russia is still inferior to the leading countries by the use of electronic banking services. According to a survey conducted by McKinsey in 2016, only 65% of Russian bank customers use mobile and Internet banking. With that, it is worth noting that under the above survey, mobile banking in Russia performs almost twice as many functions as in European countries. Due to their later establishment, Russian banks are developing their applications in the digital era, which allowed them to hit the rating of digital banking by 2018. The proportion of respondents in Russia and European countries who have used Internet banking and/or mobile banking at least once in the last three months is shown in Fig. 1 [11].

The development of this type of bank leads also to the digitalization of operation such as loan granting. Banks are proactively designing electronic platforms for granting loans, in other words, on-line exchanges that allow you to choose the best loan terms and apply for a loan without leaving home. Other bank operations also fall under digitalization, which allows them to be competitive and highly demanded by customers and helps to effectively perform their functions and operations.

The blockchain technology also dramatically changes banking activity. It will be particularly useful in the operations of document flow management and transactions. Despite the shift to e-document management, a specific feature of the bank's activity is a large pile of paper documents, which requires a serious attitude to their accounting and selection. It is there the blockchain will help the bank reduce costs. Besides, nowadays banks have to streamline effected transactions, which can be facilitated by blockchain as an effective innovation that provides these opportunities and proposing unique business offers [12].

Thus, digitalization makes banks change the current business model. Banks reach the customer thanks to the development of digital technologies, digital products, using distance payments, etc. In their traditional sense banks have lost their importance. Now there is no longer a need for numerous departments and staff. They can be replaced by so-called digital banks. O. Tinkoff agrees with this thought and believes that in the future most customers will pass to digital banking services that will reduce the role of conventional branches. Large banks will gradually supersede small

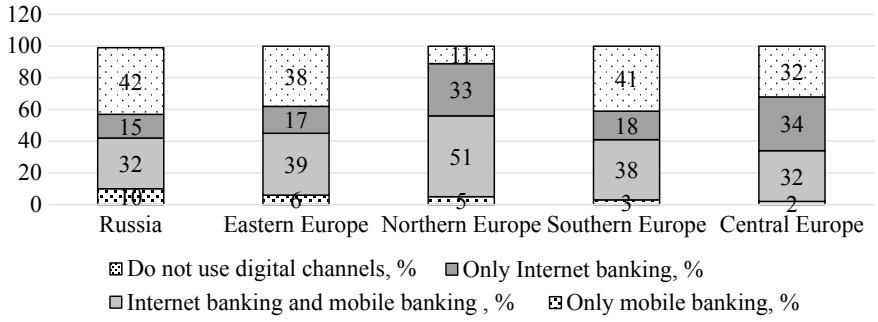

Fig. 1 The penetration of digital channels

and medium-sized banks, as the latter will not be able to invest sufficiently in the introduction of new technologies [11].

To date, there are only a few banks of this type in the domestic banking system. The most famous among them is Tinkoff Bank, which is the only online bank in Russia that services more than 7 million customers through applications and contact centers. Nevertheless, almost all large banks try to follow this path and provide distance banking services within mobile and Internet banking. The most advanced in this respect is Sberbank, which is actively putting into life modern technologies, in particular, remote servicing Sberbank-online, where you can make almost all operations (effecting payments, applying for or closing a deposit, scrutinizing lending opportunities, etc.). Sberbank Business Online application for Windows 10 provides convenient access to all services and banking products.

As we already highlighted, in modern terms the bank's competitiveness is assessed primarily by its technological capabilities, innovative products, and convenience for various groups of customers. In this regard, banks should revise their strategies and takes a decision on further long-term development with an account of the intensive introduction of Internet technologies. It is expected that large banks will deliver a full-scale digital transformation of their business and establish their own ecosystem. An example can be the ecosystem of Sberbank, which contains a whole range of additional products and services that are not fully common to banks but allowing for the expansion of the customer base. Small banks should also find their niche in this area. It is clear that the main trouble for these banks will be related to financing since digitalization is a cost-intensive measure at the initial stages that save costs only after a certain period. Therefore, the banks need to find partners or set the relevant banking alliances to put joint efforts in the development and implementation of certain innovative technologies and products. For banks with insufficient competencies, the target solution may be the provision of basic services under a foreign brand (Fig. 2) [13].

Along with that, irrespective of the size of the bank and its business model, one should apply the latest information technologies which will expand the range of banking operations and enhance bank competitiveness. Foremost, it's the employment of virtual assistants and chatbots, which should communicate with customers on all banking service issues, give recommendations and offers on individual services with regard to the recent data and changes. It is commonly supposed that in the coming years, robots will be able to replace the personal financial advisors of the bank assuming the functions of customer advising on typical issues [14]. In the opinion of Sberbank chief executive, 99% of credit decisions on individuals were made automatically in 2018.

Another application should be biometrics in the banking sector. Biometrics to a certain extent protects personal data of bank customers, as well as their accounts from fraudsters. As an example, we can mention again the largest banks, including Sberbank introducing biometrics now only for particular customers.

However, it should be emphasized that digitalization has not only positive effects acting as drivers of banks and the banking sector in general.

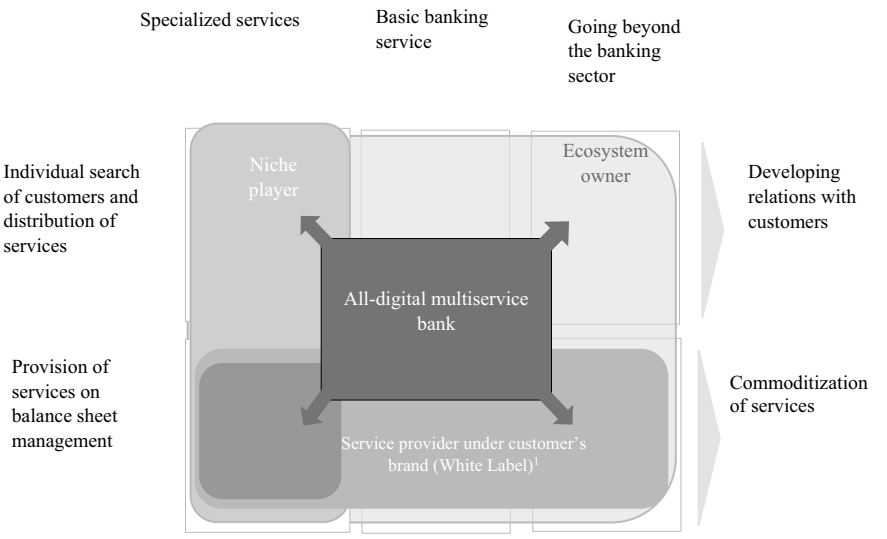

Fig. 2 Digital bank model

Like in any process, there are challenges and drawbacks. Digitalization gives rise to a hacker attack or fraud seeking to get access to customer's accounts and funds. Therefore, today's challenge for banks is to ensure the safety and security of customer's funds [15]. It takes huge costs that banks cannot always imagine, as well as appropriate technologies. To this end, the banks most often apply blockchain and biometrics mentioned earlier, as well as machine learning in operations, credit risks, and cross-sales analytics [7]. Another issue of digitalization is staff training. Learning and selection of staff will require additional costs, which is not always feasible for small and medium-sized banks. The number of skilled people is not yet enough. Moreover, the development and implementation of technologies are time- and cost-intensive too. On this premise, we should make a conclusion about the advantages of large banks over small ones by higher competitiveness and adaptation to new conditions.

4 Conclusion

Thus, digitalization as a driving factor of banking activities has a multidirectional impact. Firstly, it creates a new type of service that allows reaching the customer. Secondly, services become accessible both in terms of time and lower costs for customers buying these services. They should not be expensive and affordable for all groups of customers. Thirdly, the costs of the banks getting reduced due to cutting

offices and respectively staff and replacing traditional jobs with robots. It is worth suggesting that the digital leap that will occur in the coming years will enable banks to offer their customers not only common mobile applications and websites but also new products and services.

Legal Basis for Digital Transformation of State Control (Supervision) in the Labor Field

Svetlana E. Titor, Pavel V. Terelianskiy, and Sergey P. Kosarin

Abstract The Constitution of the Russian Federation ensures to individuals a minimum wage, labor and health protection, protection against unemployment, as well as support for disabled people and seniors. Social and labor relations have always been and will be socially tense. The state guarantees the respect for labor rights of individuals. One of the legally established methods of labor rights' protection is state control and supervision over compliance with labor laws and other relations connected with labor rights. On the back of general scientific theoretical and empirical methods, such as analysis; generalization; simulation; investigation of the government bodies performance, the regulatory framework; arrangement, structural-functional modeling, the authors theoretically underpinned the proposed amendments to the current laws in view of modern processes of the digital economy. In the age of the digital economy, the functioning of government bodies is transforming and new technologies that change approaches to the fulfillment of their functions are emerging. Modern technologies make allow establishing control (supervision) over the labor field at a markedly different angle, namely continuous electronic monitoring of the employer's actions. This approach will dramatically expand the scope of control and supervision in the labor field without augmentation of staff. Consequently, this situation will safeguard the labor rights of employees. The digital transformation of state control (supervision) in the labor field is carried out within the state policy on the establishment of conditions for the development of the digital economy in the Russian Federation. Technological changes cannot be made without legal regulation. The regulatory framework governing labor control (supervision) issues has to be updated.

Keywords Protection of labor rights · Labor supervision · Labor laws and regulations · Electronic document management · Electronic digital signature

JEL Classification K31 · M15

1 Introduction

State supervision in the field of labor is regarded as a way to protect the labor rights of individuals (Article 352 of the Labor Code of the Russian Federation). Acts of the International Labor Organization (Convention No. 81 [1], Convention No. 85 [2], Convention No. 129 [3] etc.) set forth the basic principles within which a modern labor inspection shall work. One of these principles is the primary focus on prevention. Today, it is generally accepted that it is better to prevent than punish after [4].

For the implementation of new forms of state supervision in the labor field, we have studied:

(1) the current labor laws and other regulations that contain the rules of labor law, and other regulations, including:

- letter of instruction by the Government of the Russian Federation No. ДМ-П36-608 dated January 30, 2019 "On decisions aimed at the betterment of legal and regulatory framework of control and supervisory functions";
- resolution of the Government of the Russian Federation No. 790 dated June 22, 2019 "Concerning an experiment in the Russian Federation on labeling of individual items of light industry products by identification means" (with the "Regulation on an experiment in the Russian Federation on labeling of individual items of light industry products by identification means");
- the executive order of the Government of the Russian Federation No. 792-p dated April 28, 2018 "On approval of the list of particular goods subject to mandatory labeling by identification means".

(2) draft legislative instruments, including:

- draft federal law "Concerning experiment on management by particular employers of electronic documents on labor relations with employees" (draft law No. 859678-7);
- draft federal law "On amendments to the Labor Code of the Russian Federation regarding the collection of data on labor activity in electronic form" (draft law No. 748684-7);
- draft federal law "On amendments to the Labor Code of the Russian Federation (regarding the improvement of mechanisms for prevention of occupational injuries and occupational illness, compliance with labor laws and other regulations containing rules of labor laws)" (drafted by Russian Ministry of Labor) (text as of September 28, 2018), etc.;
- draft federal law "On State Control (Supervision) and Municipal Control in the Russian Federation" (draft law No. 02/04/05-19/00091298).

(3) ongoing and implemented pilot projects on digitalization of e-document management, including:

- project "Development and technical support of a customer-oriented interactive services system for employees and employers", "Development of a software module for the Electronic Verification service (Identification Procurement Code: 191771053836477010100100340100000000);
- project "Opinion survey of employees and employers concerning the transition to the conclusion of electronic labor contract" (State Procurement Number: 0173100008517000041);
- super service project "Online Labor Relations";
- project "The concept of ensuring higher compliance with labor laws and other regulations containing rules of labor law (2015–2020)" approved by executive order of the Government of the Russian Federation No. 1028-p dated June 05, 2015;
- project "The concept of the digital transformation of bodies and agencies of the Prosecutor's office until 2025" approved by Decree of the Prosecutor General of Russia No. 627 dated September 14, 2017, etc.

(4) documents of high-potential projects, including:

- project "Concerning experiment on more advanced use of e-signature technology", (Resolution of the Government of the Russian Federation No. 1427 dated November 08, 2019);
- case law.

The current importance of digital transformation of control and supervision over compliance with labor laws and regulations is foremost dictated by modern trends in the development of the Russian digital economy [5, 6]. Moreover, in this field there are a bunch of unresolved problems:

(a) the measures to refine legal regulation for the transition to control and supervision over compliance with labor laws and regulations in digital form and overcome key legal constraints towards the implementation of the main tasks in this area are taken not to the full extent;
(b) coordination of laws and regulations governing the issues of control and supervision over compliance with labor laws and the regulatory framework of the digital economy is delaying [7, 8];
(c) modern tools and methods for integrated processing of heterogeneous data are underused, which does not allow to provide the required level of analytical support for monitoring and supervision of compliance with labor laws [9];
(d) there are no mechanisms of automated integration between information systems of the federal labor inspectorate and employers, the digital presence for an employee is unavailable in this chain;
(e) proactive and preventive measures are applied by state labor inspectors to an insufficient extent;

(f) the low coverage of entities under inspection that fails to meet the world indicators set forth by the International Labor Organization (1.6% of all inspected entities against 15–20% according to the ILO);
(g) the current number and competence of employees in the field of control and supervision over compliance with labor laws don't allow ensuring the comprehensive delivery of measures for its digital transformation with respect to integrated approach and project management principles.

2 Methodology

The study is based on the fundamental provisions of Russian and foreign experts in state control (supervision) over the labor field [10, 11].

The theoretical underpinning of the proposed amendments to the current law relies on the analysis of the modern processes of the digital economy. In the course of the research, we have employed general scientific theoretical and empirical methods such as analysis, generalization, simulation, investigation of the government bodies' performance and the regulatory framework, arrangement, structural-functional modeling.

3 Findings

The following areas can be designated for the experimental introduction of modern technological solutions in exercising federal state control (supervision) with respect to existing law, draft regulations, accomplished projects and studies, as well as lines of regulation in the field of labor relations:

- employment regulation, alteration of an employment contract terms: electronic familiarization of employees with local regulations, electronic execution of an employment contract and addendums thereto, execution of employment orders in electronic form, transfer of an employee to another job, registration of an electronic work-record book;
- regulation of liability for damage (partially): electronic execution of the contract on full liability for damage;
- advanced training: electronic registration of student agreement, the order of training assignment;
- granting a leave: electronic notification of the employee about granting leave in accordance with the leave schedule; an electronic form of leave schedule; an electronic form of granted leaves accounting (T-2 form card, leave schedule);
- working hours recording: electronic records of working hours in timesheets; electronic control over working hours;
- work-related documents: electronic submission of applications; release of documents certified by electronic digital signature;

- training in the field of labor safety and assessment of knowledge of labor safety requirements: video-based distance learning, electronic issuance of training logs.

As an experiment, employees can study on the web portal "Online Inspection.rf", where all essential training materials are published. Access to them is provided via the personal account of the employer. Also, the employee can log in the web portal "Onlinsinspektsiya.rf" through the Unified system of identification and authentication. The completion of training is confirmed automatically after listening or viewing all the materials. If the employee didn't listen or review the materials in full, the training is not confirmed. The certificate is signed by a basic electronic signature. After training, an employee passes the test on the same portal (also through authorization) and receives a certificate or other document confirming the completion of training on labor safety and assessment of knowledge on labor safety requirements by email:

- provision of PPE (Personal Protection Equipment): electronic accounting of provided PPE, a receipt is confirmed by a basic electronic signature of the employee (or biometric data), scanning bar codes for workwear labeling (an experiment on workwear labeling has been carried out since December 1, 2019);
- distribution of milk and healthful-dietary meals: electronic accounting of distributed milk and healthful-dietary meals, a receipt is confirmed by a simple electronic signature of the employee (or biometric data), scanning of bar codes for workwear labeling (an experiment on dairy products labeling to be launched since June 1st, 2020);
- other issues in the field of labor safety: electronic execution of legal documents in the field of labor safety: regulations on the occupational safety service and other local regulatory enactments in the field of labor safety; an order of assignment of a labor safety engineer duties to a company's specialist on a part-time basis or conclusion of agreement with outsourcing company on employment of labor safety specialists; job description of a labor safety engineer; other orders on appointments in the field of labor safety; programs of initial and basic trainings on labor safety; a list of professions and job positions of employees who do not need to pass workplace labor safety training; list of labor safety instructions for company's employees; a list of occupations and types of works performed in the company and other lists required by laws and regulations in the field of labor safety; electronic estimate of costs for measures on improvement of working conditions and labor safety; electronic documents confirming that the company finances measures on improvement of working conditions and labor safety in the amount of at least 0.2% of the overall cost of production; a list of groups of employees, as well as a list of names of those who should pass periodic medical examinations; schedules of preventive and predictive maintenance of production facilities and routine inspections and maintenance of vehicles and other schedules in the field of labor safety. The legal force of documents and familiarization with them can be confirmed either by a basic or enhanced unqualified electronic signature both on the part of the employee and employer;

- wages: electronic notification of employees about the constituents of wages and the amount of other payments to the employee, leave allowance pay, dismissal compensations and other payments due to the employee; amount and grounds of withholding of wages in the accounting period; the total amount of money to be paid. Legal force of documents and familiarization with them can be confirmed by a basic electronic signature of the employee and employer;
- granting guarantees and compensations: electronic execution of orders and documents on secondment of an employee, electronic distribution of maternity leave and childcare leave to the age of 3 years, electronic execution of orders on granting of other guarantees and compensations. The legal force of documents and familiarization with them can be confirmed by a basic electronic signature of the employee and employer.

The study showed that experimental implementation of modern technological solutions is unsuitable when exercising federal state supervision over the dismissal of an employee, imposition of disciplinary sanctions, investigation of industrial accidents and occupational illness, investigation and bringing an employee to liability for damages. The above procedures may have the nature of a labor dispute, therefore they don't come under federal state supervision.

4 Conclusion/Recommendations

A study of existing laws and regulations within the problem under consideration (digital transformation of state functions of control (supervision) in the field of labor) (Titor, S.E.: Bodies of control and supervision over compliance with labor legislation in Russia [12]. Thesis for a Candidate Degree in Legal Sciences, Saratov Law Institute of the Ministry of Internal Affairs of the Russian Federation. Saratov 2009), revealed the following areas of changes:

1. The conversion of HR workflow management and document management in the field of labor safety into electronic-digital form.
2. Making electronic monitoring and electronic off-site surveillance legal.
3. Upgrading the technologies for the exercise of control and supervision functions in the labor field in digital form.
4. Restructuring the interaction between employee and the employer in a digital form, including reciprocal rights and duties.
5. Digitalization of employee awareness through the implementation of personal accounts.

First of all, the amendments should be introduced to the Labor Code of the Russian Federation. Several principles of change should be highlighted:

(1) the wording "against signature" in the rule should be added with a basic electronic signature Myshko and Kudryashov [13], an enhanced uncertified electronic signature (hereinafter—EDS). However, sometimes the use of electronic

digital signatures is unjustified in the sense of the rule itself and may well be replaced by sending an electronic notification via official communication channels defined by the employer [14, 15]. The electronic forms can be defined and set forth in a collective agreement, an employment contract, as well as local regulations. This form can be used, for example, to notify an employee of leave time in accordance with the leave schedule (Article 123 of the Labor Code of the Russian Federation);

(2) the wording "written form" in the rule need to be supplemented by the electronic form signed by the enhanced uncertified electronic signature of the employee and enhanced certified (or certified) signature of the employer. Such forms can be used when concluding an employment contract, or contract on liability for damages, or a student contract, or addendums to an employment contract;

(3) the wording "written consent" applied in the rule can be altered in two ways. In the events when the employee's written consent to particular acts is also confirmed directly by the voluntary acts themselves (for example, attending job on a weekend or holiday, etc.), we find it possible to replace the "written consent" with/or the consent received in electronic form via official communication channels specified by the employer. In the events when the subsequent acts of the employee can be deemed compulsory submission of the employee to the employer, the possibility of giving consent by means of an enhanced uncertified electronic signature (for example, when the employee is transferred to another job);

(4) as concerns the wording "written statement" in the rule, the principle stated above should be adhered;

(5) changes relating to the transition to electronic document management at the stage of experimental implementation of HR workflow management system should necessarily provide: a) the right of the employer to electronic document management (HR and one in the field of labor safety); b) the right of the employer to use of equipment with remote video and audio surveillance functions, other information and electronic interfaces; c) the right of the employee to refuse the electronic communication with the employer (if it is acceptable in view of the employer's technologies and peculiarities of work); d) the duty of the employer to monitor and maintain the operability of all information systems, equipment, devices, etc.;

(6) the rules of labor law governing the relations between the Federal Service for Labor and Employment of the Russian Federation (Rostrud) and the employer should be amended in respect of:

- employer's duties to provide Rostrud with documents in electronic form upon request, as well as connect to a remote monitoring system in the field of labor safety and HR document management;
- the respective rights of the Federal Service for Labor and Employment of the Russian Federation in electronic form.

The analysis of law enforcement practice shows that the written forms of personnel procedures in labor law can be converted into electronic form, save particular situations that may lead to a labor dispute:

- regulation of relations with socially disadvantaged categories of employees: disabled people, women, and other persons raising minor children, persons under 16 years, to prevent risks of negative and controversial implications. Physical, physiological, psychological, and other peculiarities of these categories may hinder the execution in electronic form;
- governance of relations concerning the resolution of individual and collective labor disputes, because of the high risks of disputes;
- regulation of relations connected with controversial situations that may result in an individual labor dispute (for example, procedures for dismissal of an employee and others).

GR Management as an Innovative Model of Interaction Between Business Entities and Public Authorities in the Context of Digital Transformation

Iakow I. Kayl, Veronica S. Epinina, Roman M. Lamzin, Elena V. Zudina, and Julia M. Azmina

Abstract The paper considers the features of organization and effective functioning of GR-management in the digital transformation context. It is proved that in this context the relevance of GR interaction is explained, on the one hand, by obstruction of the internal structure of the modern society, which is accompanied by other processes, other interests and the formation of outside interests and groups, and, on the other hand, by increased state intervention in the spheres of social life, expansion of legislative and administrative initiatives of the state, which began to actively affect the interests of business. The analysis showed that the effective organization of GR-management contributes to the removing of administrative barriers to business development, improving the efficiency of the business entity. It is proved that the importance of GR-management is determined by the need to disclose the potential capabilities of business entities that are essential for the development of territories in the context of digitalization, which should ensure the identification of targeted mechanisms for supporting business for the rational diversification of the economy. The digital economy policy in the concept of business development as the main source of state tax revenues should be aimed at increasing the activity of entrepreneurial structures. Based on the results of the study, author's recommendations on overcoming the existing difficulties of the effective development of GR-activities in the Russian Federation are proposed. The prospects for further research are based on the

1 Introduction

The current state of management as a science and practice is characterized by the emergence of a large number of theories and concepts that often do not have a clear definition and interpretation. In particular, such situation is developing within individual branches of management. This fully applies to GR-management—one of the new and relevant trends, the interpretation of which has not been established in Russian management yet. Due to the fact that absolutely all business entities interact in one way or another with public authorities on various issues, GR-management is actively developing all over the world.

The nature of interaction process between business entities with public authorities affected by many factors: historical traditions, the established nature of relations between the state and society, the institutionalization level of relations between business entities and public authorities, the methods adopted by the state for resolving disputes between business and government, and others.

Depending on these factors, conditions for GR-interaction of business entities with public authorities are created. The existing conditions form certain rules, methods and norms adopted in a particular state that determine the existing GR-management model. As a result, the GR interaction process can develop in different ways. This can be either a process of coordinating the positions and interests of the interaction subjects, proceeding in a dialogue format, or a one-sided process. In the second case, interaction is limited to informing business entities about the rules and regulations established by the state without taking into account their interests.

2 Materials and Method

As a scientific material, we used scientific publications on the problems of establishing partnerships between business entities and public authorities. The paper uses methods of comparative and system analysis, graphical modelling, and logical approach, providing the necessary depth of the scientific problem elaboration.

3 Discussion

The basis of the categorical research apparatus is GR (Government Relations)—management, which is understood as the targeted influence of business entities on the processes of making state and municipal managerial decisions to protect their own interests and build long-term, transparent, partnership relationships with public authorities by achieving a balance of interests.

The study draws on fundamental and applied research of the authors on the issues of business entities and public authorities interaction, including works [1–21].

In addition, as a result of a comprehensive content analysis of the existing scientific literature on the research topic, the authors did not find publications on the formation of an innovative model for the interaction of business entities with public authorities in the context of digital transformation, which allows us to define this topic as understudied by modern economic science and requiring further scientific research.

4 Results

The actual socio-economic problem for GR-management is the development of entrepreneurship. The joint results obtained by business entities and public authorities in the process of building a GR-interaction may relate to receiving any government subsidies, benefits, premises for rent, concluding an agreement for a joint strategic partnership and other issues. As you know, a business cannot fully develop without interaction with public authorities. It is necessary to establish effective and efficient contact with public authorities to solve many problems (subsidies, state support, etc.) and the further development of business entities depends on how well this dialogue is built.

As a rule, state policy of entrepreneurship development proceeds from the provision of necessity to support and remove socio-economic barriers. The USA, Belgium, Germany, the Czech Republic and a number of other countries are successfully pursuing a support policy and receive the expected positive effects from business entities. Features of GR-management in developed countries are presented in Table 1.

Government of the Russian Federation and public organizations are actively involved in implementing measures to support entrepreneurship and are considering new initiatives and proposals to improve the infrastructure for the creation and functioning of business structures.

The legislation of the Russian Federation establishes the main directions for the development of dialogue between business entities and public authorities. So, the concept of long-term socio-economic development of the Russian Federation for the period until 2020 provides for the adoption and implementation of measures to form and operate a favorable business environment. According forecast of the socio-economic development of the Russian Federation for the period until 2024, measures

Table 1 Features of GR-management in developed countries

Countries	Features
Russia	1. It is at the stage of formation 2. GR-activity is not fixed by law 3. Weakly distinguishable from other concepts in society 4. Adaptation of "foreign" models of GR-management 5. GR-services are developed only in large companies
USA	1. GR-activity is fixed by law 2. Based on the idea of mediation between business and government 3. Open and honest activity 4. Administrative pressure policy 5. Prohibited third-party hiring of GR-specialists
The European Union	1. GR-activity is fixed by law 2. A complex system consisting of a large number of levels 3. The development of industry organizations is one of the main trends 4. Officials prefer to interact with certain sympathetic organs 5. Knowledge of English is required to conduct business

Source Compiled by the authors

are taken to reduce the costs of doing business, to promote the development of small and medium-sized enterprises, to improve dialogue between business entities and public authorities.

The Russian Federation has developed a wide range of traditional tools that can be used by business entities for GR interaction with public authorities (see Fig. 1).

The document fixing the main features and rules of communication and interaction of business entities with public authorities and officials is Federal Law dated 02.05.2006 No. 59-FZ (as amended on 12.27.2018) "On the Procedure for Considering Appeals of Citizens of the Russian Federation". The law regulates the rules of communication with public authorities and officials, individual instruments of interaction, as well as the rights and obligations of the parties. The law defines two instruments of interaction with public authorities: appeal and personal reception.

The basis for the distinction of appeals are the actions that the applicant wants to carry out. Three types of hits are distinguished depending on the content:

1. Statement—a citizen's request for assistance in the exercise of his constitutional rights and freedoms or constitutional rights and freedoms of others, or a report on violation of laws and other regulatory legal acts, deficiencies in the work of public authorities and officials, or criticism of the activities of these bodies and officials.
2. Offer—a citizen's recommendation to improve laws and other regulatory legal acts, the activities of public authorities, the development of public relations, the improvement of socio-economic and other areas of activity of the state and society.
3. Complaint—a citizen's request for the restoration or protection of his violated rights, freedoms or legitimate interests or the rights, freedoms or legitimate interests of others.

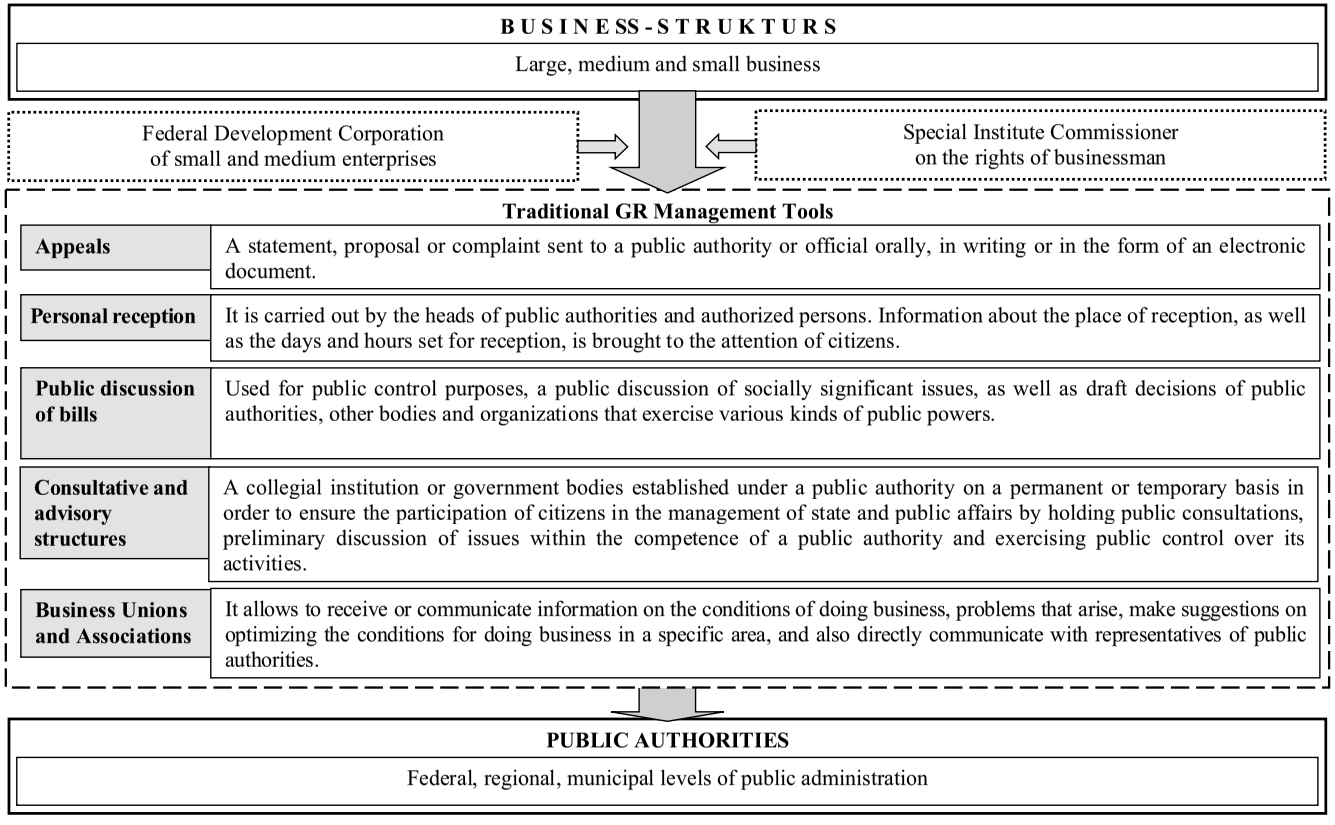

Fig. 1 GR-management model with traditional interaction tools. *Source* Compiled by the authors

In this case, an electronic appeal refers to the applicant's appeal received at the e-mail address of a public authority or posted in a special section on the official website of a public authority on the global computer network Internet.

Another channel for interaction with public authorities provided for by the Law is a personal reception. The rules for holding a personal reception are set in detail: the time frame for the reception is fixed, the duties of the heads of public authorities, the rules of conduct within the reception.

The legal regulation of the public discussion of draft laws is enshrined in Decree of the Government of the Russian Federation of 08.25.2012 (as amended on 10.31.2018) No. 851 "On the procedure for disclosing by the federal executive authorities information on the preparation of drafts and regulatory legal acts and the results of their public discussion". A public discussion of the draft laws was introduced with the aim of improving the quality of the preparation of regulatory legal acts, which regulate, among other things, entrepreneurial activity, as well as pursuant to Decree of the President of the Russian Federation of May 7, 2012 No. 601 "On the main directions of improving the public administration system".

Consultative and advisory structures are an effective channel for interaction between business entities and public authorities. Consulting and advisory bodies existing in the Russian Federation today, in which business entities can potentially participate in order to promote, protect and coordinate interests, can be divided into the following main types according to their functions and focus of activity:

1. Coordination councils—are created to maintain interaction between different actors and coordinate their activities, with the aim of agreeing opinions and positions on any one issue or topic. For example, on March 14, 2020, a coordinating council for the fight against coronavirus was created in Russia, which included an operational headquarters, an economic commission, and heads of regions.
2. Interdepartmental (or intersectoral) councils—can be created both for the coordination functions of various public authorities in the framework of solving a problem, and for obtaining expert opinion or conducting an examination. Their feature is the participation of various departments and entities whose powers overlap on a specific issue or topic. For example, in the Rostov region there is an interdepartmental coordinating council for tourism—a permanent collegial deliberative body created to improve the interaction of the executive authorities of the Rostov region with the tourism industry, law enforcement and regulatory authorities on the formation of a competitive tourism industry that contributes to the social and economic development of Rostov area and providing ample opportunity to meet the need Russian and foreign citizens in tourist services.
3. Public advisory councils—are deliberative, advisory and expert bodies participating in public discussions of draft normative legal acts on issues that may have a significant impact on the conditions for conducting entrepreneurial activity (for example, a public council is formed and operates under each committee of the Volgograd Region Administration) Decisions of the public advisory council are advisory in nature to the public authority at which it was created.

In addition to the above tools for communication and GR-interaction, civil law also determines the ability of business entities to create associations in the form of associations or unions that are non-profit organizations. The purpose of such organizations is to coordinate entrepreneurial activity, as well as to represent and protect common property interests.

It should be understood that associations and business unions do not have specialized and unique tools for interacting with public authorities: they use legislatively fixed mechanisms that are also available to other legal entities. However, an important advantage of such organizations is that they express a collective opinion, which provides them with a certain superiority when interacting with public authorities on issues of promotion and protection of interests in comparison with private companies expressing their individual interest.

It should be noted that an important place in the GR-interaction of business entities with public authorities is occupied by the Federal Corporation for the Development of Small and Medium Enterprises created in 2015. The Corporation operates as an institution for development in the field of small and medium-sized businesses in order to coordinate the support to small and medium-sized businesses of the entities stipulated by the Federal Law of July 24, 2007 No. 209-FL "On the Development of Small and Medium-Sized Enterprises in the Russian Federation" after the name change Joint Stock Company Non-Bank Deposit and Credit Organization Credit Guarantee Agency. To solve the current problems of violation of rights, bureaucratic pressure, corruption, administrative barriers in contact with business in Russia, a special institution of the Commissioner for the Rights of Entrepreneurs has been created. He has the right to defend the interests of business in court, to suspend departmental and normative acts until a court decision, and to apply to the court as an interim measure with the operational suspension of officials.

In the context of the transition of industrialized countries to a new technological structure of the fourth industrial revolution, digital transformation is increasingly called among the most important prerequisites for successful national development, and digital technology is becoming increasingly important in the process of GR management as a communicative strategy for mutually beneficial and targeted interaction of business entities with public authorities authorities. The Internet allows business entities to overcome geographical, institutional and bureaucratic barriers and directly or indirectly influence the process of public administration decision-making.

In the context of electronic impact on public authorities, business entities use the following innovative GR-management tools:

- submission to public authorities of open emails and appeals with the preliminary collection of signatures under them;
- distribution of personal emails with requirements and proposals to representatives of public authorities;
- creation and promotion of social online advertising;
- activity for receiving responses (resonance) in social networks.

Cherkashchenko T. A. uses the concept of "electronic GR communications" and defines them as a type of PR communications carried out through online media, search

engines, social networks and Web 2.0 technology, aimed at creating and maintaining a system of direct and indirect interactions of a social subject with public authorities in order to create a favorable environment for the functioning of this subject.

The high potential for the use of electronic tools in the digital economy is determined by the general integration of electronic-digital space in the life of society. Such trends determine GR-interactions based on the use of modern communication technologies as a factor in the commercial success of a business. Based on a communicative approach, the electronic channels of GR-management are classified into Internet channels used by GR-management specialists for technologies of direct appeal to public authorities, and Internet technologies of indirect influence through an appeal to third parties (media, scientific and business community, mobilized public), when through the online discussion and promotion of a certain topic on the network, the interest of Internet users is formed, the attention of traditional media is attracted and indirectly appears influence on decision-makers in public administration. The innovative GR-management model with electronic interaction tools is presented in Fig. 2.

At the present stage, new social network media, like all types of Internet practices that work in accordance with the WEB 2.0 principle (social networks, instant messengers, blogs, etc.), being at the peak of their global popularity, have become an important channel for mediated GR interaction between business entities and public authorities.

Effective tools for virtual GR influence can be the services of the most visited Vkontakte network in the Russian Federation, such as public (through "wall posts") and private (through personal messages) user interaction, commenting, automatic rating and viral "repost" of the published content, attaching media files, documents and tags on the map, organizing polls with filtering the results and statistics of the dynamics of the votes cast, creating "events" for holding mass meetings location, tracking user activity through the news feed.

A common technology for digital GR communication is hashtags—tags used to distribute messages on topics on blogs and social networks. The hashtag service is launched on Twitter, Facebook, Instagram, Pintest, YouTube, Vkontakte. Hashtags are a simple and convenient filter when searching or discussing hot topics in real time on the Internet, can increase the reach of a web audience or identify Internet users with certain interests, being an effective tool for researching the political market before planning GR campaigns on social networks.

In the context of GR-management for network political crowdsourcing technologies, web portals are intended for public discussions of the legislative acts projects or for placing online petitions as specially designed interactive platforms that allow all interested parties, both experts and unskilled Internet audience, to post comments, suggestions and comments on acts projects on a voluntary basis and on principles of parity, to vote for the project as a whole or its individual articles, to get acquainted with the results of their public discussion and assessment of the regulatory impact, as well as to submit appeals to public authorities in the remote mode, after collecting the necessary number of signatures established by law to support the projects proposal.

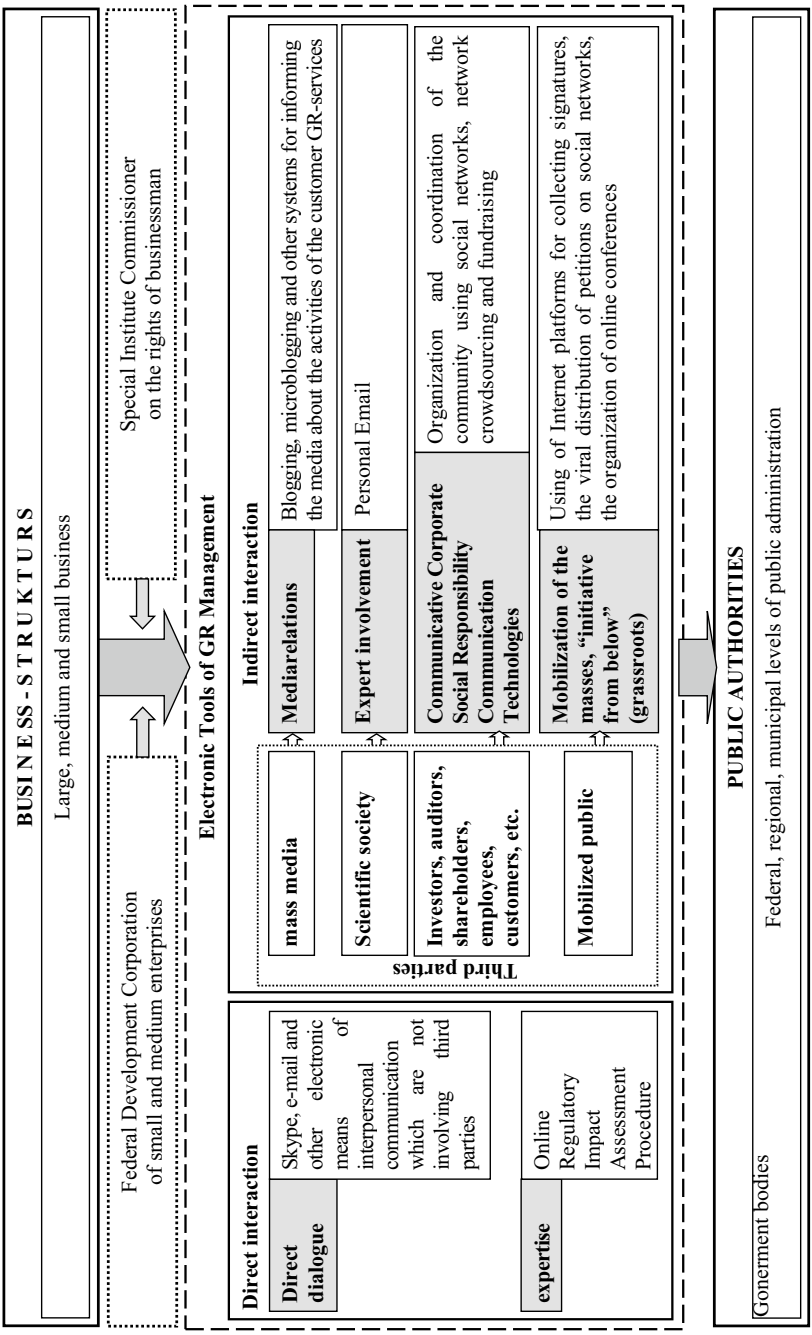

Fig. 2 Innovative GR-management model with electronic interaction tools. *Source* Compiled by the authors

According to the current Russian legislation, since 2013, as part of developing the system "Open Government" (https://open.gov.ru/), in the context of intensified dialogue between business entities and public authorities in making managerial decisions, one of the elements of the domestic public institution of online—discussions is the placement of information on normative legal acts projects being developed by the federal executive bodies and on the results of their public discussion on the single federal web portal of the normative legal acts projects (https://regulation.gov.ru/). In 2015, the Ministry of Economic Development launched the official state electronic resource "The Assessment of Regulatory Impact" (http://orv.gov.ru/), aimed at taking into account the opinions of the widest possible range of interested parties and at obtaining the reliable information on the appropriateness and possible consequences of introducing the new regulation through public discussion of bills by representatives of the business community.

In the Russian Federation there is the Internet resource "The Russian Public Initiative" (https://www.roi.ru/) to place citizens' initiatives for which it is necessary to collect at least 100 thousand signatures in their support in order to be sent to public authorities for consideration.

The educational trend of the fourth industrial revolution in the coming years will be the emergence of new professions that will require the brand new competencies that are at the intersection of several industries. In fact, a domain expert in GR-relations of business entities with public authorities should become a moderator and mediator of an online dialogue between business and officials, an information systems architect, a technical specialist of smart-contract verification, etc.

5 Conclusion

The territories' development in the context of digitalization is determined by the need to disclose potential business opportunities. GR-management provides the understanding for business entities and public authorities about the priority areas for developing entrepreneurial activity in order to organize its support and stimulation. GR-interactions can be carried out in relation to analysis and diagnostics: areas and industries strategically significant for the territories' development; directions and industries that are smooth-running in the territories in the context of digitalization; industries that fell into a phase of recession or decline in the conditions of innovative and technical lagging behind the position of market digimatic management.

The problems of developing GR-management in the Russian Federation concern not only the business itself, but also the state as a whole. Nationwide, GR management faces the following challenges:

1. GR-management is confused with other concepts—PR and lobbyism. At the same time, GR-management and PR have different objects of managerial influence, and lobbyism is one of the tools of GR-management and has a political

coloring, despite the fact that it is very developed as an independent management mechanism.
2. The lack of the institutional mechanism for regulating GR-activities, inconsistency of the legal aspect with the development of information technologies.
3. Some institutions are not ready for the transition from shadow lobbyism to civilized GR-management. This is due to the absence of the law on regulating lobbying activities. The shadow lobbyism has strengthened in the public authorities of the Russian Federation. And the shadow lobbyism is a pass to the political elite. This is evidenced by the fact that the representatives of businesses leaders prefer to solve problems behind the scenes, using the levers of power that are in the shadows.
4. The desire of the majority of business entities to cooperate with the executive authorities, rather than with the legislative authorities, where the made decisions have the legal framework.

In order to overcome the complexities of the effective development of GR-activities in the Russian Federation, in our opinion, it is necessary to solve a number of problems:

1. Development and approval of the institutional framework for the interaction of business entities with public authorities within the framework of GR-management. At the same time, it seems urgent and beneficial to develop the single standard for interaction between public authorities and business entities, searching for information and obtaining services in the "one contact" model, which is realized on the web portal "gov.ru".
2. Creating the favorable competitive environment for domestic enterprises, lowering administrative barriers to market functioning, including the elimination of bureaucratic procedures.
3. Transplantation of effective foreign experience in using the GR-management elements into the practice of Russian business structures.
4. Stimulation of creating an institute for assessing the efficiency of GR-activities by involving the public in this process.
5. Digitalization of public administration, including the creation of GR forums.
6. Promoting the profession of a GR professional by active introducing the relevant educational programs in higher educational institutions, as well as creating upgrade training courses.

Acknowledgements The reported study was funded by the Russian Foundation for Basic Research, grant No. 19-010-00103 "Cognitive modeling of innovative mechanism of partnership of business entities and public authorities (GR-management) in the conditions of digitalization"

Transformation of Russian Banks Business Models in the Conditions of the Digital Economy Development

Tatyana Yu. Mazurina, Elizaveta I. Shamanina, and Klavdiya L. Neopulo

Abstract The article reveals the main prerequisites for the digital transformation of banking business models, analyzes the advantages and threats of the development of digital financial technologies, as well as the factors hindering the transition of Russian banks from the classical business model to the digital format. The authors examined the most promising trends of digital technology development and scenarios for the further transformation of the banking business into a digital economy. The article also presents separate recommendations for banks on the successful conversion of their business models to digital format.

Keywords Digital transformation · Bank business models · Digital financial technologies · Digitalization

1 Introduction

Over the past few years, a number of significant changes have taken place in the financial and banking sectors in particular, due to the development of new technologies. Over the years, new participants found it rather difficult to enter the financial services market. Recognized large financial institutions, the so-called traditional participants, had advantages in size, in the breadth of the client base, in resources, in a developed network of territorial presence. They quickly developed and refined their systems to

E. G. Popkova et al. (eds.), *Socio-economic Systems: Paradigms for the Future*,
Studies in Systems, Decision and Control 314,
https://doi.org/10.1007/978-3-030-56433-9_66

meet the increasingly complex requirements of regulators, which guaranteed them the conditions necessary for them to flourish, even in difficult economic situations.

Today, innovative technologies are rapidly changing the market, and dynamic companies, often high-tech start-ups focused on a specific innovative technology or process covering all areas—from mobile payments to insurance—are taking the lead in the market.

Usually we consider banks as participants of the financial market, which are included and control all stages of the life cycle of operations, taking on the risks of potential financial losses, while in today's environment banks are increasingly acting as intermediaries, leveling the risks, or becoming one of the links in the network of operations.

Financial institutions should seriously consider the technological challenges of the economy and take advantage of new opportunities to create digital partnerships with both other market intermediaries and end-users of services in order to minimize costs. In the new digital reality, when both companies and the public become more technologically advanced, customers will strive to reduce the cost of purchased services, increase their convenience and availability.

Already now it is possible to note dynamic changes both in the financial markets as a whole, and in the structure of the market of banking services.

In line with the technology paradigm, banks are seeking to transform their business models, increase the availability and scope of their services, and increase their market share through new online financial distribution platforms (e.g. marketplaces). This leads to the development of partnerships between banks and technology organizations, as well as with non-financial companies.

It may be noted that new banking products based on the development of digital technologies, as well as non-banking products created in partnership with other companies, will be promising directions for banks in the new environment [1].

This conclusion can be supported by materials of the research of the international auditing company Deloitte, according to which the main factor of long-term growth in the banking business will be customer focus [2]. Banks will further strive to increase the level of service, quality and efficiency, as well as the range of products and services provided.

2 Methodology

The methodological basis for the research was the fundamental concepts and positions of domestic and foreign scientists in the field of banking and digital technologies. The results of the study showed that in the context of the development of digital financial technologies we can observe a constant increase in the frequency of interaction of consumers of financial services with new digital services and platforms.

The authors used general methods of scientific cognition: observation, comparison, contrast, expert evaluation method. The system method was the main way to generalize the information received while writing the article.

It should be noted that, due to their "youth", the issues of digitalization of banking business are only beginning to be studied by Russian and foreign authors. It may be noted that the main provisions and concepts in the field of banking, finance, strategic and innovative development of the economy are widely disclosed in the works of Russian economists: Lavrushina [3], Kostyuchenko [4] and others.

Besides, some issues related to the process of transformation of the Russian banking system in the conditions of electronic technologies development are considered in Korotkov's [5, 6], Nazipov's [7], Yarygina's [8] dissertation studies.

The impact of the digitalization of business processes in the bank on reducing costs and interest rates is described in the works of Ushakova [9]. The necessity of control in the field of digital services and possibilities of growth of fraud are noted in works of Khalin and Chernova.

The information base of the article also included scientific publications, materials of periodicals and open sources of the Internet on the subject under study, as well as analytical reviews of the world's leading consulting and auditing companies (McKinsey & Company, KPMG, Deloitte) in the field of digital economy.

3 Results

3.1 Transition of Bank Business Model from Classical to Digital Format

However, a Cisco study conducted in 2015 shows that banks were not in a great hurry with digital transformation. Thus, 43% of 7200 respondents (bank customers) in 12 countries said that banks did not understand their customers' needs, 37% doubted that banks would be able to help customers achieve their financial goals, 28% of respondents did not trust the slogans "better interest rates", 25% had the intention to move to another bank with more modern and convenient services [10].

However, the impact of new financial technologies is inevitable, and this leads to the emergence of new format banks, i.e. digital banks. For the most part, they are focused on the retail client. Such banks have no branches, front offices, they provide services remotely, using mobile applications and websites.

Tinkoff Bank, for example, is the same in Russia. It was one of the first Russian digital banks (established in 2006) to have no branches and no large staff. And this bank has proved its effectiveness over time.

The digitalization of the Russian banking sector is a noticeable trend of our time. Banks are now changing their traditional business models, transforming a significant part of information technology, which concentrates all areas of the bank's activity.

In general, the business model is essentially a product line of the bank, which is reflected in the structure of its balance sheet. If a bank has a wide range of products for its customers, we can talk about its universality. And if a bank focuses on certain operations, then we can talk about its specialization.

It should be noted here that in world practice there are three main types of business models [11]:

– "traditional model ("brick-and-mortar"), in which financial institutions are represented in the traditional, physical market and do not provide a full range of services over the Internet;
– online model ("pure play", "click-only") implies the provision of financial services exclusively through remote channels;
– integrated model ("bricks-and-clicks" or "click-and-mortar") involves a combination of traditional customer service channels and online modes of financial services".

And banks in the future will have to change their business models and adapt to growing customer demands. Two scenarios are possible here. The first is the digital bank itself. The second is the bank-platform, where new products are developed and created.

Most likely, the operating banks will go the second way.

Until recently (in the traditional model) the sales system of almost any bank was built predominantly through a network of offices. In the classic form, the bank's organizational structure included a number of business units focused on providing specific types of products: loans, deposits, bank cards, investment products, etc. The top level in this structure were the departments of retail and corporate business, as well as the department of work with small and medium-sized businesses. At the same time, the largest link in the hierarchy was the branch network management unit, often united in a bank with operational management. The classic business model of the bank with a wide network of sales offices is shown in Fig. 1.

In such a model, all business indicators are allocated to the sales office network and subsequently assigned to it. In turn, the head bank acts as a supplier of products and technologies, provides advertising, technical and consulting support.

With digital transformation and changing consumer expectations, such a classic business model faces a number of significant challenges that can be attributed to it:

- customer focus of the business;
- development of equal channels of communication with clients;

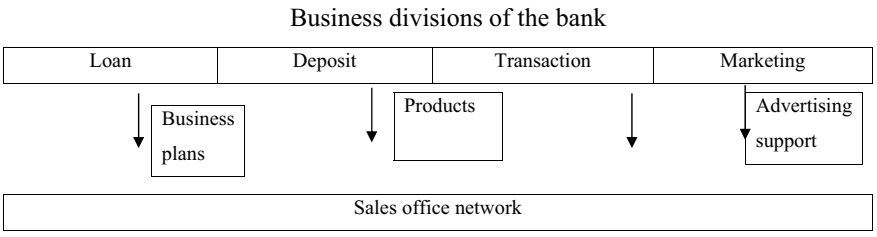

Fig. 1 Classic business model of the bank with a wide network of sales offices

- digital brand promotion;
- individual product offers;
- distance service online.

All the above factors make the classical banking business model less viable and competitive. In this regard, there is a need for structural transformation of the bank's business processes and key areas of responsibility of their managers.

According to the research of the international consulting company McKinsey&Company, the introduction of digital technologies in emerging markets allows banks to significantly reduce costs for customer service, including costs associated with servicing customer accounts—by 65–75%; cash withdrawal—by 40–60%; bank transfers—by 90–95% [12].

Today, a number of large Russian banks are already confidently demonstrating the results of the digital transformation of their business. These include Sberbank, Tinkoff Bank, Kiwi Bank and Alfa Bank, which are actively investing in IT technologies and improving the qualifications of their staff.

The use of digital technologies by banks in the context of a discrete system based on methods of coding and transmission of information refers to remote customer service via the Internet and mobile channels. Banks are actively developing and implementing separate projects, for example, "Digital Mortgage", which allows customers to get a mortgage loan without visiting the bank's office or with the participation of the bank's partner, automates the application processing and reduces the role of the human factor.

At the same time, according to the research of international audit company KPMG, the basic restrictions faced by financial organizations at introduction of innovative technologies, are following: insufficient maturity of processes, absence of corresponding competences, low level of IT-literacy (Fig. 2).

What will the bank need to successfully transform its business model into a digital format [14]:

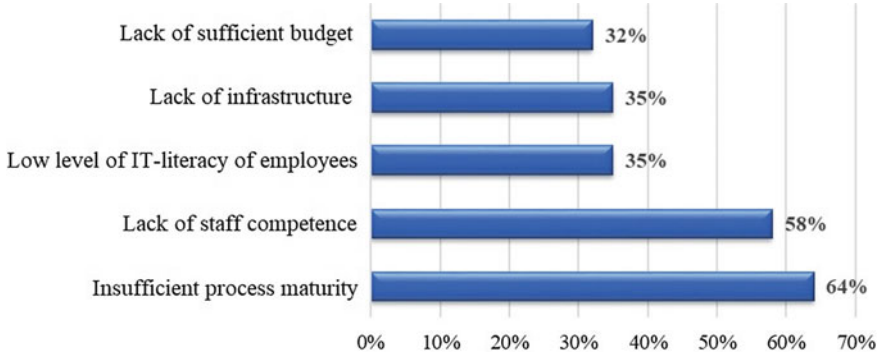

Fig. 2 Main conditions limiting the implementation of innovative technologies [13]

(1) marketing unit that performs the tasks of studying customer behavior and defining target audiences to work with, as well as forming requirements for developing a line of banking products and services for strategic customer groups;
(2) business units seeking to rapidly develop and bring to market new products, services and technologies together with the IT unit;
(3) CRM unit, which plays a key role in automating customer segmentation, planning and executing marketing campaigns in all channels, and managing the sales funnel;
(4) channel owners units: working channels of a wide network of sales offices require actual support from regional directorates, ensuring continuous professional development of staff and quality control of services offered; for remote channels it is enough to correctly integrate CRM with IT systems.

Measuring the current level of digitalization of a classic bank is a very nontrivial task, and today there is no single approach to assessing the degree of digitalization, with some general guidelines, such as:

- level of business process automation;
- development of self-service channels (available services and channels);
- speed of operations (in real time and offline);
- level of Big Data management;
- 24-h service availability;
- speed of change, time to bring business solutions to market.

These parameters characterize the efficiency of the bank's work with clients in the digital environment (they show the share and volumes of online sales, as well as volumes of service operations).

Thus, the bank's success in the new digital realities directly depends on the bank's readiness to change its business model, promptly transform business processes and improve their technological efficiency.

In the future, digitalization of business processes will create opportunities for the bank to compete not only at the service level, but also in price range. Thus, a reduction in the creditor's expenses leads to a reduction in the prime cost of the product, which is reflected in interest rates. Depending on the share of digitized services and volume of investments, the interest rate can be reduced by 0.1–0.5% points [9].

3.2 How Innovations will Change the Russian Banking Industry

According to the forecast of international consulting company McKinsey&Company, on horizon till 2030 the Russian banking sector has chances to become the most advanced in the world in the field of business digitalization. Thus, according to analysts of McKinsey&Company, digital technologies significantly reduce the expenses of banks (on average, by 10–15%); technologies of Big Data will allow

banks to reduce risks, providing an opportunity to evaluate the client as accurately as possible at the stage of granting a loan; a significant share of income of banks will fall on non-banking services [15].

Let's consider the basic directions of introduction of innovative technologies in banking activity:

(1) Product innovation. Drivers of innovation in this area will be: Big Data analysis, Computer-Assisted Teaching (CAT), artificial intelligence, robo-advisig, in-depth analytics and blockchains.

Examples of the introduction of technologies into the banking business include the online mortgage service of Tinkoff Bank or client identification by photo when making transfers at Otkritie Bank.

(2) Process innovations. The main benefits of digital transformation for traditional banks are a multiple reduction in costs and acceleration of banking operations. In this regard, small banks will need to focus on point development of certain key technological competences or use platforms of other market participants to outsource certain functionality.
(3) Innovations in business models. This direction of innovations will develop in the following vectors: partnership relations, provision of banking products and services under another's brand, creation of ecosystem and new business directions. In this case, the bank's strategic partners will be the aggregators of user data and information (e.g., telecom operators and social networks) that provide access to external customer data.

In view of the above, the following measures are to be implemented by market participants:

- developing a clear strategy that will include a plan for product, process and business model innovation;
- monitoring the activities of FinTech companies and start-ups on the market, identifying the most promising ones, and then creating strategic partnerships;
- developing missing competences and new skills in digital technology, human resources management and understanding of customer needs;
- transformation of the corporate culture of banks.

3.3 Challenges, Threats and Risks of Digitalization of the Russian Economy and Banking Society

The exponential transition to digital technologies is driven by the need to address a wide range of challenges, including the following:

- established mentality of cautious perception of everything new from the Russian business;
- strong commodity dependence of the Russian economy;

- insufficient investment in fixed assets of the real sector of the economy, including investment in the introduction of new technologies;
- contraction of the venture capital market in Russia due to the tense political and economic situation, as well as unfinished issues related to the support of innovative projects at different stages of their implementation;
- lack of qualified personnel;
- emergence of unscrupulous users of new digital services;
- digital fraud;
- the risks of inadequate legislation and regulatory frameworks that accompany digitalization processes;
- risks of misuse of the technology and the new possibilities associated with digitalization (e.g. unauthorized use of someone else's personal information).

The rapid development of digital technologies also carries certain threats directly to business, such as deteriorating manageability of processes, reduction in the number of jobs, information security risks.

To reduce or eliminate groups of identified risks, both at the business and economic levels, it is necessary to develop programs to manage them. Implementation of such programs at all levels of economic life will allow to take advantage of digitalization and bring the economy and business development to a more effective level.

3.4 Importance and Role of the Banking System in Promoting Digital Financial Technologies

If presented as a percentage of the technologies used in the financial sector, it would look as follows: Big Data—84%; chatbots—60%; OCR—56%; robo-advising—56%; AI—40%; blockchain—32%; VR/AR—16%; IoT—12% [13].

Russian banks fulfill an important social mission in terms of ensuring access to financial services both for citizens and for organizations of all organizational and legal forms of ownership. In this connection, the banking sector is more receptive to the introduction of technologies and is ahead of other sectors of the economy and social life in terms of scale and degree of their application. Banks are the main drivers of digital transformation of the entire industry of financial services and ecosystem creation, which fundamentally change the format and ways the real and financial sectors interact.

4 Conclusion

It is believed that two vectors (scenarios) are possible in the trajectory of future banks development. The first one is the digital bank itself. The second one is the bank-platform. And while the digital bank has limited functionality—payments, currency

exchange, capital management services, the second is a platform on which new products and services are created and offered jointly with non-financial companies.

Thus, the digital reality is gradually becoming a natural environment for Russian banks, and sooner or later traditional banks, depending on their resources and objectives, will choose some combination of these two scenarios, since each bank, in order to remain competitive and continue its activities, will have to change its business model and become digital or digitize certain areas of its business to fully meet the increased needs of its clients.

The digital transformation of the banking business and changes in the business models of banks will not only help to preserve the customer base, but will also contribute to the expansion of the banking business by reducing operating costs, the use of modern distribution channels for products and services, and closer cooperation with customers.

Use of Digital Technologies in Diagnostics of Functional Condition of the Russian National Basketball Team 3 × 3 Players

Raisa I. Andrianova and Marina V. Lenshina

Abstract Currently, innovative technologies are widely used in the world of sports, including computer, digital, smart- and video technologies. The identification of human capabilities at the utmost level is impossible without modern high-tech equipment. On the eve of the 2020 Summer Olympics in Tokyo, digital technologies allow us to accurately analyze the competitive and training process, develop a training algorithm, plan the amount of loads based on the state of the athlete, which is extremely important for timely entry into a sports form and to demonstrate the highest result. The study of the functional state of the players of the female youth team of Russia 3 × 3 basketball on the basis of assessing heart rate variability indicators was carried out to correct and optimally plan physical activity, prevent overtraining of athletes and conduct necessary recovery measures.

Keywords Digital technologies in sports · The youth team of Russia · 3 × 3 basketball · The multispectrum complex · Functional state

JEL Codes I26 · I29

1 Introduction

The men's and women's 3 × 3 basketball teams of Russia have won the right to participate in the Tokyo Summer Olympics on the basis of the ranking performance in major international competitions of the main, youth and junior national teams of Russia.

During the training camp [1], the teams underwent ongoing examinations at the beginning, after separate stages of training microcycles and at the end of the training

camp to assess health and tracking the dynamics of the body's adaptation to training loads in preparation for the main competition—the World Cup stages and its final stage in the Novogorsk training center.

During the sports fees, an express assessment of the functional state was carried out to identify the response of the athlete's body to high loads, timely correction and selection of the optimal exercise regimen [2]. This assessment is based on the method of analyzing heart rate variability recommended in world practice [3–5]. The indicators of which are highly correlated with the medical data of the functional state of the athlete and the results of performance in competitions.

Analysis of heart rate variability (HRV) allows you to determine the prevailing type of autonomic regulation, which is important to consider while planning the training process and correction of loads [6]. Scientists note the individual types of regulation of the vegetative system of the body, as a result of different adaptations to training and competition loads [7].

2 Methodology

The study involved players of the female youth team of Russia (under 23 years old), in the amount of seven people, all athletes are qualified as Master of Sports, average age—21.4 ± 1.2 years, average experience—12 ± 1.4 years. The survey used the universal innovative complex "Multispectrum".

The capabilities of the program-diagnostic complex are very wide. It includes modules, which allow a comprehensive basic assessment of the athlete's condition in a number of medical areas: ECG, electroencephalography, myography, spirography, rheography, and the state of the central nervous system.

The complex is a Russian development of scientists, with the help of it, the state of athletes has been successfully monitored for several Olympic cycles. It should be noted that this diagnostic system is certified and is successfully used in the research of highly qualified athletes of the national teams of the country in various sports. In this case, modern software and digital technologies help the medical coaching staff to solve the problems of effectively preparing athletes for competitions of the highest international level.

Diagnostic testing aimed at assessing the regulatory mechanisms of the body of athletes according to heart rate variability included a background test for 3 min (in the supine position) and an orthostatic test for 4 min. The study took place at the beginning of the retracting microcycle training.

3 Results

In a number of scientific works, the predominant activity of the sympathetic and parasympathetic departments of the nervous system in the regulation of heart

rhythm was distinguished [3], but currently the importance of the autonomous and central contour of physiological functions [4] is emphasized, which is provided by many links of a single regulatory system. The classification of types of heart rate variability provides for four types: with a predominance of the central circuit—moderate (type 1), pronounced (type 2) and with a predominance of the autonomous circuit—moderate (type 3), pronounced (type 4).

Digital technologies make it possible to interpret data on heart rate variability and issue an opinion on a number of indicators of the functional state of the body [8]. Based on the data on the activity of the cardiovascular system, the trainer, together with the doctor, decides on the possibility of further increasing or decreasing the training load [9].

Autonomic balance in the analysis of heart rate variability is determined in the supine position. During the orthostatic test, when moving to a standing position, vegetative reactivity changes, which is an indicator of the adaptive capabilities of the body of athletes. At the same time, heart rate indicators are of an individual nature; a number of scientific papers speak of an "individual portrait" of heart rate variability [4, 6]. Therefore, the averaged indicators in the group don't fully reflect the occurring functional changes in the activity of the heart of each player studied.

The nature of the reaction to an orthostatic test depends on the prevailing type of HRV regulation [10]. As can be seen from the data in Tables 1 and 2, autonomic regulation prevails in basketball players, with an increase in the activity of the parasympathetic department of the autonomic nervous system. In this case, low heart rates are observed at the level of 51–53 bpm and the presence of mainly high-frequency oscillations in the HRV spectrum.

According to TP indices (total spectrum power), high data are observed among the majority of basketball players, reflecting the total effect on the heart rhythm of all levels of regulation. The power of high-frequency waves HF, which indicate the activity of the parasympathetic center, is two times or more, higher than normal for healthy people who are not involved in sports. The power of low-frequency waves, which determine the activity of sympathetic centers according to LF indicators, is also higher than normal for most basketball players.

High rates are also characteristic of the power of very low frequency VLF waves, which represent the activity of central ergotropic and humoral-metabolic mechanisms of heart rate regulation.

After the orthostatic test, a decrease in the power indices of all spectra of TP, HF, LF, VLF waves, especially high-frequency HF waves, or the activity of the parasympathetic center was observed, and the relative LF% increased.

The coefficient of vagosympathetic balance LF/HF is significantly increased in all the studied patients, which indicates activation of the sympathetic nervous system. Also, the stress index IN increases, the requirements for adaptation of the body increase. Such a reaction to an orthostatic test is characteristic of the type of heart rate variability with a predominance of an autonomous circuit.

Only player №7 has a paradoxical character of change of indicators—TP, LF, VLF increase after orthostasis, instead of their decrease.

Note M—arithmetic mean, m—standard deviation

Table 3 The ratio of the activity of the parasympathetic and sympathetic nervous system in the heart rate variability of basketball players

№	Parasympathetic nervous system activity	Activity of the sympathetic nervous system and hormonal regulation mechanisms
1.	Above the average	Below the average
2.	Low	High
3.	Middle	High
4.	High	Middle
5.	Above the average	Below the average
6.	Below the average	High
7.	Above the average	Low

It should be noted that controlling heart rhythm is a complex process [11], which is characterized by individual regulation of the autonomic system of the body (Table 3), as a result of different adaptations to training and competitive loads.

A feature of the Multispectrum hardware-software complex is digital data processing and the ability to present them in the form of integrated assessments of the functional state of the body, understandable for perception and decision-making on the further use of training and competitive loads.

In the study, a computer complex based on calculated indicators produced the following data:

- current functional state, taking into account the category of athlete (FS);
- integral assessment of the functional state (AFS), which is a comprehensive indicator that takes into account the athlete's condition at rest and the reaction to the functional test;
- an assessment of the functional reserves at rest (AFR) reflects the overall activity of the athlete's regulatory systems under relatively favorable conditions, indicates the potential ability of the body to adapt to stress;
- an assessment of the rationality of the expenditure of functional reserves (ARR), shows how economically the body spends reserves in response to the standard load, reflects the stability of regulation to external influences;
- the coefficient of rhythm variability (C 30/15) with an orthostatic test, which indicates adaptation disorders. In the case of its decline, a conclusion is made about moderate or severe overtraining of the athlete. 30/15 shows the activity of the parasympathetic division of the ANS and is one of the criteria for the functional state of the body.

The results of the study at the beginning of the training camp (Table 4) indicate the good functional condition of most athletes and their readiness to perform significant training loads. A training regimen without boosting maximum loads was recommended for athletes №1 and №6.

Table 4 Indicators of the functional state of athletes at the beginning of the training camp

№	FS	AFS	AFR	ARR	C 30/15
1.	Satisfied	2.55	3.85	1.67	Below the average
2.	Good	3.20	2.47	3.37	High
3.	Good	3.13	3.17	2.80	Above the average
4.	Very good	3.63	4.71	1.41	Above the average
5.	Good	3.19	3.96	2.01	Middle
6.	The border	2.27	2.73	2.44	Below the average
7.	Very good	3.70	4.85	3.22	Middle

After the shock microcycle with significant loads, the functional state of the athletes with load correction (№1 and №6) changed in the direction of improvement (Table 4). At the same time, the deterioration of the functional state of other players (№3 and №4) was recorded, which also required timely correction of the load for these athletes in the subsequent microcycle, and the necessary recovery measures.

After gathering together before leaving for important competitions, most players had a good level of functional state, which was taken into account when forming the national team.

4 Conclusion

1. During the study, the heart rate variability indicators of qualified young basketball players at rest and after an orthostatic test were determined, which reflect the individual nature of the regulation of the autonomic system, and as a result, they have different adaptations to training and competitive loads.
2. Multiple monitoring of the functional state on the basis of the Multispectrum software package made it possible to constantly carry out load correction taking into account the state of the athletes, which affected the team's final sports result. So, in many round games and the Super Final of the League of Nations—2019, a competition of the strongest young players in the world, the women's team won first place. The Russian team has silver at the World Cup in the age category up to 23 years. Thus, the youth team made a significant contribution to the rating of the Russian 3 × 3 basketball team, on the basis of which the right to participate in the 2020 Olympics was obtained.
3. The using of modern digital equipment, multifunctional complexes with possible remote access to receive telemedicine consultations, express analysis and interpretation of the obtained data on the athletes' functional state made it possible to optimize the training process, make timely corrections to load planning, restore and further improve the performance of basketball players.

Digital Scouting Technologies in Game Sports

Raisa I. Andrianova and Dmitry V. Fedoseev

Abstract Today's professional sport is impossible to imagine today without a systematic analysis of a large amount of digital data. In game sports, in particular in basketball, Smart technologies are used for selection of basketball players, analysis of game activity, scouting, prediction of results and many other aspects of sports activity. To increase the competitiveness of Russian basketball at the international level, it is necessary to introduce the latest digital technologies and monitor global trends in the application of the capabilities of artificial intelligence to build the training process and scout gaming activities.

Keywords Artificial intelligence methods in game sports · Digitalization in basketball · Scouting · Scout report · Effectiveness of throws in zones · Analysis of statistical data

JEL Codes I26 · I29

1 Introduction

Today, the sport of top achievements is based on the analysis of a large amount of digital data. Preparation for a separate match requires scouting and analysis of statistics of game actions, and each opponent needs an individual approach [1, 2]. The next step in the use of computer technology is the construction of an effective training process for professional teams, which is based on algorithms that are products of processing a huge amount of reliable digital information for various indicators [3, 4].

E. G. Popkova et al. (eds.), *Socio-economic Systems: Paradigms for the Future*,
Studies in Systems, Decision and Control 314,
https://doi.org/10.1007/978-3-030-56433-9_68

In most cases, the collection and processing of digital data by Russian trainers is carried out mainly manually, which is an extremely energy-intensive and time-consuming process.

In the American Basketball League, the NBA is actively using the capabilities of artificial intelligence. In particular, the SportVU program (2013), which is a system of cameras that collect data in real time.

Based on sophisticated software and statistical algorithms, SportVU provides detailed statistical information about the movement of the ball, the location of the players and creates a database with the ability to search for movement diagrams of each player [5]. The Bhostgusters program has become widespread, which considers not a single player on the site, but all the players as a whole.

This allows the coach to designate the attack tactics in a special application and determine the intended form of defense of the opponent.

Since 2017, American coaches have been actively using the improved Second Spectrum program, with which you can track statistics of successful and unsuccessful actions, types of throws for each player in various situations [6, 7].

The creation of such algorithms implies the formation of a technology for analyzing massive digital data in the area of sports, their processing and the rational application of the results in practice [8, 9].

The objectives of this study:

1. To identify the features of scouting women's basketball teams based on the analysis of digital data;
2. To develop an algorithm for assessing the effectiveness of shots in the zones of individual players and the team as a whole;
3. To formulate recommendations for adjusting the training process, depending on the results of scouting and analysis of the effectiveness of throws in zones.

2 Methodology

During the study, the authors used a method for comparing and analyzing qualitative and quantitative indicators, analysis of game protocols, video surveillance, statistical methods, and graphic methods.

3 Results

In the Russian basketball league, several teams actively use artificial intelligence methods. Among them, the Rostov-Don-Southern Federal University basketball club, which plays in the Super League division of the 1 Russian Championship, should be highlighted. The season 2016–2017, when the team took fourth place, can be taken as a reference point. This is due to the fact that starting from the 2017–2018 season, the coaching staff began to actively use statistical analysis of big data in their

work and build their training and competitive activities based on the results obtained. In the last two Russian Super League Championships №1, the Rostov-Don-SFedU team won gold. In the season 2018–2019, it became the winner of the East European Basketball League. In the 2019–2020 seasons, the Rostov-Don-SFU basketball club once again occupies a leading position.

If we analyze the final statistics for the last four seasons, we should note the annual increase in the main game indicators. In the 2019–2020 seasons, basketball players of the Rostov-Don-Yufu club demonstrate record high sales of two points. (48.5%) and free throws (77.6%), an active play on rebounds (49 rebounds per match) (Table 1).

On the example of training the coaching staff of the Super League Rostov-Don-SFU team for a series of matches, we consider one of the game aspects that it's advisable to pay special attention to—the effectiveness of the opponent's throw in the areas of the court. It should be emphasized that the algorithm of actions presented below is used in scouting before each series of matches (Fig. 1).

To obtain adequate information, the attack zone is divided into 14 sectors, where the first sector is a three-point zone in the corner, and 14th sector is a zone under the football ring. The number of attacks made and the number of goals scored is entered in the protocol, then the percentage of throws from each individual sector is calculated.

Table 1 Final statistics for the seasons of the Rostov-Don-SFU basketball team

Season	2 points (%)	Penalty points (%)	Rebounds	Effectiveness
2016–2017	43.00	70.50	39.4	70.4
2017–2018	43.80	71.50	40.9	72.6
2018–2019	42.40	77.10	46.5	78
2019–2020	48.50	77.60	49	84.9

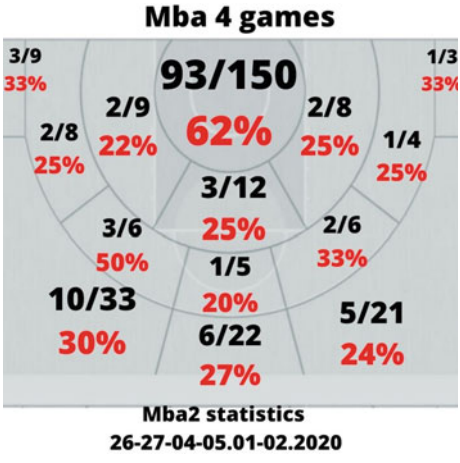

Fig. 1 Team-wide throwing performance on site zones

The result is a schematic drawing that allows you to identify the most dangerous areas of attack of the opponent and those sectors that don't pose a particular threat. This information is extremely important in order to correctly place the emphasis of the defensive actions of the team.

The data array is quite voluminous, because a professional women's team per game makes an average of about 80 throws from the middle and far zone (over 5 thousand throws per season). As a rule, in order to prepare for a specific game, the performance of the opponent's four previous games is analyzed, it's necessary to take into account about 320 throws (the team completed 175 two points, 91 three points and 95 penalty points).

From the figure, we can conclude that the team carries out the bulk of successful attacks from under the ring, with a high percentage of hits. From the middle and far zone throws are less productive. Next, the algorithm of team protective actions is made: (1) protection should be aimed at containing deep passages; (2) difficulty transferring the ball into the area under the ring; 3) cutting off the attacking players after the attack in order to maximize the difficulty of picking up the ball on someone else's shield.

After the main trends for the opposing team have been identified, it's advisable to analyze the performance in the zones of the opposing team leaders.

Based on the analysis of digital data for game statistics in a season, six basketball players were identified in the opposing team who receive the most playing time and are actively involved in the attack (Figs. 2 and 3). For each of the players, all attacks over the past 4 matches are calculated and the results are entered into tables, the performance is determined by the sectors of the site, and individual performance drawings are prepared by zones.

The coach's task is to identify the strengths and weaknesses of the opponent's leaders on the basis of the information received, develop an algorithm for technical and tactical actions in defense and convey it in an accessible form to the players of his team [4].

As a rule, information about the opponent is provided in the form of scout reports. In addition to a graphical representation of the effectiveness of the throws of the

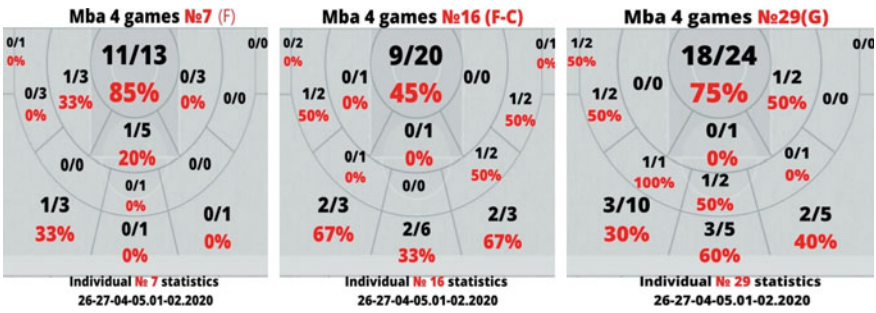

Fig. 2 The effectiveness of the throws in the zones of the site of the leading players

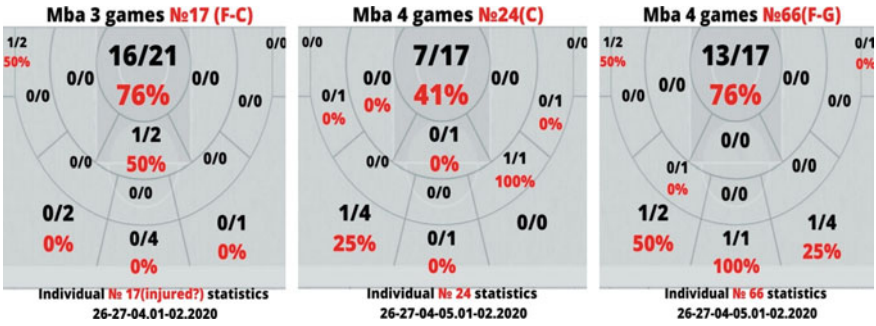

Fig. 3 Efficiency of throws in the zones of the site of the leading players

team leaders in the zones, video cuts with the participation of certain players for visualization and deeper monitoring can be shown (Table 2).

This analysis of performance by sector of the site is relevant not only when analyzing the opponent's team game, but can also be useful for the coach in terms

Table 2 Scout report on individual actions of the opposing team leaders

Player number, role	Strengths	Weaknesses	Defense game algorithm
№7 forward	Pass and attack from under the ring	Long and medium range throws	Play at a distance, close the passage, provoke a medium and long throw
№16 forward	Long and medium range throws	Pass and attack from under the ring	Play tightly, close the possibility of a throw from a distance, direct into the passage
№29 playmaker	Long and medium range throws; Pass and attack from under the ring	Universal game technique, without weaknesses of preparedness	A tight game throughout the court, making it difficult to get the ball
№17 center	Pass and attack from under the ring, beat under the ring	Long and medium range throws	Play at a distance if the player is far from the ring, provoke a medium and long throw, close the passage, make it difficult to get the ball under the ring
№24 forward	Pass and attack from under the ring	Long and medium range throws	Play at a distance, close the passage, provoke a medium and long throw
№66 playmaker	Long and medium range throws, проход и атака из-под кольца, высокая скорость	Universal game technique, without weaknesses of preparedness	A tight game throughout the court, making it difficult to get the ball

of adjusting the training process and increasing the proportion of throwing exercises from areas with a low percentage of hits.

It's advisable for each player to maintain individual tables and build graphs, which reflect the dynamics of points scored per game and the percentage of scoring from the game throughout the season (Figs. 4 and 5). The trend line in the figures allows you to identify the general trend of the analyzed indicators.

The tested player is the member of Rostov-Don-Yufu team, since the beginning of the season he has been demonstrating the growth dynamics of the points scored per game and the percentage of scoring from the game in the 2019–2020 seasons.

In the case of a decrease in the percentage of scoring from the game, an algorithm of actions is make to improve performance to the required level: (1) providing the player with reliable information regarding the current problem; (2) conducting individual throw training; (3) increased control over the attacking actions of the player in the process of team training [10, 11].

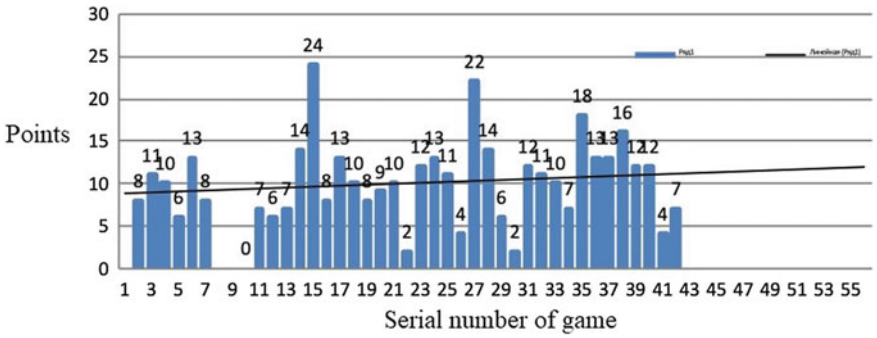

Fig. 4 Dynamics of player points scored in Rostov-Don-Yufu in the 2019–2020 seasons

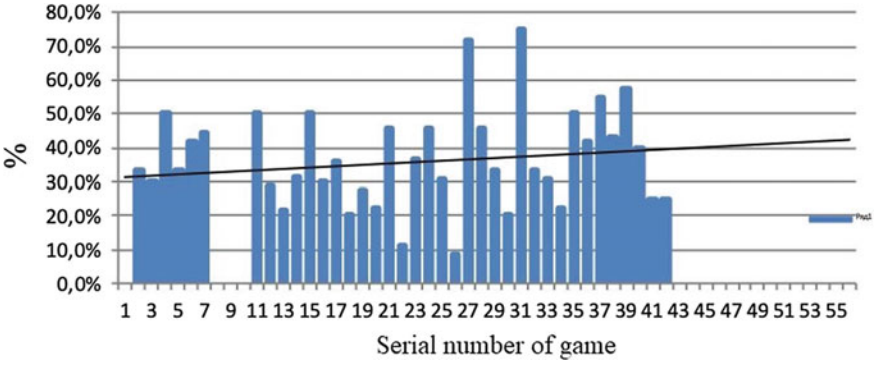

Fig. 5 Dynamics of the percentage of sales throws made by the player Rostov-Don-Yufu in the 2019–2020 seasons

Table 3 Statistics of the player Rostov-Don-Yufu from 2016 to 2020

Season	Number of games	Playing time (min)	2 points (%)	3 points (%)	Penalty throws (%)	Total percentage (%)
2016–2017	43	16.3	31.4	17.6	90.0	26.9
2017–2018	41	15.6	39.1	35.4	87.5	38.2
2018–2019	56	20.9	33.2	28.5	89.6	31.5
2019–2020	41	23.7	41.1	26.4	85.5	36.5

You can track the dynamics of performance by comparing the player's performance by season. The table shows the statistics of the tested player, starting from the 2016 to 2017 seasons to the present. The applied methodology for assessing game activity and the construction of the training process, which is based on deep scouting, has largely contributed to the player achieving the highest percentage of two points in the past four seasons, maintaining the overall percentage of the game at a fairly high level. The player's statistics are presented in Table 3.

4 Conclusion

The effectiveness of zone shots is only one of a large number of analyzed indicators. As practice shows, a good result is greatly facilitated by competent scouting based on monitoring a large number of digital data.

The modern infrastructure of professional sports represent that at all levels, from the organization of the federation and leagues to the specific training session, the digitalization process is permeating ever deeper. Making an increasing number of decisions in the area of sports is carried out on the basis of the analysis of large-scale data, which leads to a need for the application of the capabilities of artificial intelligence.

To increase the competitiveness of Russian basketball at the international level, it's necessary to introduce the latest technologies and monitor global trends in the application of artificial intelligence to make the training process and scout game activity.

Digital Transformation of Government Procurement on the Level of State Governance

Shakizada U. Niyazbekova, Roza Zh. Kurmankulova, Svetlana P. Anzorova, Makka G. Goigova, and Zeinegul K. Yessymkhanova

Abstract The research examines the digitalization of government procurement. We studied the countries' experience, such as Colombia, Peru, Chile, and Ecuador, in the digital transformation of public procurement, which affected the government sector at all levels. Today, to become digital, organizations must compete in a world where both end consumers and business customers expect products and services to meet their needs on demand through channels.

Results:

1. It was found out that adaptation is necessary for development in dynamics.
2. The analysis shows the importance of increasing the influence on half of the organization's expenses by purchasing an organization and improving the efficiency of managing the expenses.
3. Presented artificial intelligence, which is an important monitoring tool for digitalization of government procurement.

JEL Codes O10 · O20 · O30

1 Introduction

Every day the society is faced with the terms "digital economy", "blockchain", "digitalization", "innovation" and understands that all of this is relevant in any activity and work.

Digital procurement automates repetitive tasks to improve efficiency and reduce costs; it provides real-time information and Analytics to stakeholders around the world using artificial intelligence (AI) and easy-to-use online tools; it introduces new and smarter ways to implement data for day-to-day operations and decision-making.

Besides, it transforms the interaction of buyers with suppliers and other third parties, serves as a platform for new levels of cooperation.

Various government procurement authorities test the technologies they use to optimize processes, gain visibility in their data, collaborate with their suppliers, manage categories and contracts, and much more. Government procurement leaders want the best because they are now more cognizant and informed than ever been before. More often they are learning from the transformation of digital procurement in the private sector and paying more attention to technological trends.

2 Background and Methodology

The instrumental and methodological apparatus of the research is based on analysis and synthesis, the method of induction and deduction, analogy, system approach, structural and functional approach, and perspective methods. These methods in their interrelation allowed us to study the subject of this work comprehensively and make objective conclusions and generalizations. The subject of the research is the methods and tools for testing the digitalization of government procurement.

3 Discussion and Results

Currently, abroad there is research in government procurement, such as the "government procurement Review of public establishments" and the "government spending Forum". The government is getting smarter and looking for cloud platforms that could cover all their needs from source to payment to customized for the needs of individual establishments. They understand that to have an impact, solutions must be modern and convenient for all users, including final users, suppliers' purchasing.

Innovation's pace continues to accelerate. The reinterpretation of purchases continues. To realize the potential of the future, you need to start now. As the

digital revolution spreads across all industries, organizations will face unprecedented competitive pressures.

Digitalization creates new channels for interaction with customers and partners, which expands the main business-models and dynamics of the industry. In turn, organizations see their future relevance and viability.

Directors know that their organizations must become more flexible and efficient in order to survive and develop in this competitive world. Therefore organizations seek to use digital broadcasting to transform key business areas. The main tasks were customer-oriented, such as marketing, sales, service, and supply chain functions.

A digital purchasing organization automates repetitive tasks to increase efficiency and potentially reduce costs. It provides stakeholders across the business with real-time access to analytical data and Analytics using artificial intelligence and easy-to-use online tools. It makes new and more clever ways of implementing data models for the enrichment of daily operations and decision-making. And it also changes the way buyers interact with suppliers and other third parties, serving as a platform for new levels and types of collaboration. The digital transformation has affected many sectors and industries, including government procurement.

Today, most discussions focus on the potential of the digital revolution for transforming government procurement into a knowledge-based function. Digitalization and the use of new technologies can utterly change the methods of government procurement.

Government procurement started its journey towards digital transformation with the introduction of electronic government platforms (e-GP). In the early stages of digitization, Procurement 2.0 moved from traditional price-based purchasing to recording data and transactions using e-GP and managing digital processes. Procurement 3.0 went further and e-GP systems began to work and interact with information outside of their data ecosystem, and make business decisions, not through transactions, but intellectual capabilities and content management.

The next step towards the digital frontier is Procurement 4.0: a revolution driven by growing digitalization and the use of technologies such as artificial intelligence, cognitive and automation processes that transform organizations and the purchasing function. This will create a value of using big data analytics for better decisions, drive innovation, and integrate data to improve user interaction and vendor performance.

The transformation process is gradual, and government procurement systems around the world are at different stages of the digitization process. Chile uses artificial intelligence and blockchain, and some states are still implementing transactional platforms or are even on the verge of developing their very first e-GP systems. Continuing their path to digital transformation, in the early stages of implementation countries can now make an exponential leap and use the experience of other countries to take advantage of new technologies. For example, Jamaica with the support of the Islamic Development Bank, the government sector processes contracts within three months.

The digital transformation of government procurement has affected all levels of public administration.

For example, Colombia, Ecuador, and Peru move towards greater administrative decentralization, and local authorities develop and implement more effective policies.

The implementation of breakthrough technologies in procurement can help local governments stimulate growth and support their modernization process. Subnational governments seek to develop a comprehensive strategy for implementing data use, digital processes and tools, and new institutional capacity to harness the digital revolution.

Quality control and monitoring of performance are becoming important for public organizations because they are subjected to close attention and also provide better services to citizens. Effective quality control requires a streamlined supply chain and better visibility of suppliers.

To get a sense of a supplier's performance and risks required large collaboration between agencies or different government structures, and they must be part of a larger transformation strategy to be effective. Government procurement managers should keep in mind a strategy for monitoring and improving the performance of suppliers by several indicators. The following points need to be solved:

1. Is there a place where suppliers can register?
2. Do the supplier's key performance indicators support it?
3. Is it possible to interview suppliers or users?
4. Is it possible to track contractual obligations?

The future of government procurement involves a fundamental transformation of its function. As it gets digital and automated, public procurement officers continue to shift away from routine and administrative tasks. During the process's progress, they need to adapt and focus on strategic thinking and developing technical skills. This is a great opportunity to strengthen the strategic role of government procurement.

The dynamic, complex, and the disruptive context in which Procurement 4.0 operates will require new ways to monitor processes. Blockchain is becoming an excellent ally in the war against corruption, ensuring the integrity and transparency of government procurement transactions. If the data can move freely and transparently, then processing can be done. Applications such as smart-contracts that can execute code in a distributed network allow you to optimize your purchasing processes.

Artificial intelligence is an important monitoring tool, especially in searching for errors in data sets. AI of government procurement can search for discrepancies between costs and prices, quantity, frequency of orders, as well as several other patterns that will help suppliers detect potential fraud/errors and predict purchasing models. The development of AI-based purchasing observatories is becoming more common. Technologies such as drones, tablets, and smart cameras are used remotely to track the status of work and improve project supervision.

Data management is a key component of Procurement 4.0. Machine learning methods, along with statistical algorithms, make it easier to aggregate, process and analyze big data from diverse sources. The result will be useful in understanding current, future relationships and trends. Predictive Analytics can optimize costs and identify cost trends, risks, and opportunities.

4 Conclusions

Thus, the implementation of digitalization is full of challenges and opportunities. Governments and individuals must be prepared to orient on the digital transformation of procurement, change their business models, and develop creative and innovative ways of thinking. A new generation of procurement employees characterized by analytical and creative thinking requires government procurement to be intensively digitized. It is necessary to adapt to develop in a tough and dynamic era. It's also important to increase the influence of the purchasing organization on half of the expenditures and to improve the efficiency of managing these expenditures.

Oil and Gas Investment Opportunities for Companies in Modern Conditions

Shakizada U. Niyazbekova, Olga S. Ivanova, Buldyryk Suleimenova, Saltanat K. Yerzhanova, and Rysty K. Berstembayeva

Abstract The article discusses the company's oil and gas investment opportunities. Abroad, venture capital companies provide opportunities for direct investment in the growing oil and gas industry. With extensive experience in developing horizontal oil and natural gas fields, venture capital firms use long-term industry knowledge to provide their partners with high-yield investment opportunities that allow them to diversify their investment portfolios and ensure a stable cash flow while simultaneously getting the right to benefits and significant tax. Venture companies are constantly working to reduce the risks associated with oil and gas projects by partnering with the best operators in the industry. This article discusses the company's oil and gas investment opportunities. Abroad, venture capital companies provide opportunities for direct investment in the growing oil and gas industry. With extensive experience in developing horizontal oil and natural gas fields, venture capital firms use years of industry knowledge to provide their partners with high-yield investment opportunities that allow them to diversify their investment portfolios and ensure stable cash flow and simultaneously entitle benefits and significant tax. nies constantly working to reduce the risks associated with oil and gas projects by partnering with the best operators in the industry.

Results:

1. Presented analysis of the world's leading oil and gas companies.
2. Shown various ways to invest in oil and gas.

Keywords Financial investments · Investment attractiveness · Investors assessment mechanism · Economic viability

JEL Codes O10 · O20 · O30 · P33 · P47

1 Introduction

The goal of the study is that oil drilling remains an investment opportunity with the greatest potential. The US has a long history of entrepreneurs who found opportunities to invest in oil wells that have resulted in huge dividends. This is a good time to invest in oil wells.

2 Background and Methodology

The instrumental and methodological apparatus of the research is based on analysis and synthesis, the method of induction and deduction, analogy, system approach, structural and functional approach, and perspective methods. These methods in their relationship allowed an in-depth study of the subject of this work and make objective conclusions and generalizations. The subject of the research is the methods and analysis of the development of oil companies. The methodological basis of the research is based on fundamental provisions, concepts, structural approaches, and methodological basis.

3 Discussion and Results

The analysis revealed that the Chinese group Sinopec took the first place in the list of the world's leading oil and gas companies with revenue of 430 billion USD in 2019, ahead of Shell and Saudi Aramco. According to the company's filings, American oil and gas company Exxon Mobil ranked sixth this year with total revenue of about 275 billion USD in 2019.

Triple-digit sales in billions are not uncommon in oil and gas companies in this industry. However, earnings dependent on the price of crude oil on the world market. Sinopec has integrated both as energy and chemical businesses into its operations.

Saudi Arabia's oil company, Saudi Aramco, was the newcomer to the list in 2018, and this year remains the only known, renowned indicator for the company. In April 2019, Saudi Aramco for the first time placed bonds worth about 12 billion USD on the exchange to prepare for the IPO, which was eventually postponed until December. The Saudi Aramco is still largely controlled by the state, it has published financial figures for the first time, previous accounts remained mostly secret because the company was nationalized in the 1970s.

Oil makes the world go round. Oil demand remains high because it is an efficient way to generate both BTU (British thermal units, a measure of energy) and kilowatt-hours. Oil has many implementations in industry, as it is a key component in creating plastics.

Natural gas is a popular source of energy for heating and cooking. This can be converted into diesel fuel and electricity, and it's also important in the production of chemical fertilizers. While crude oil and gasoline prices are relatively high compared to historical norms, with adjusted inflation, natural gas prices were close to a 10-year low at the beginning of 2012. This creates a natural point for purchase if demand for natural gas is increasing—or if supply will fall—it leads to higher prices.

There are different ways to approach investments in oil and gas. For example, you can consider the industry as a collection of companies that provide goods or services to consumers, and other players in the oil and gas industry itself.

You can approach the industry as a product and seek to profit from changes in the price of crude oil, gasoline, diesel, and other products.

1. Mutual funds or ETFs. As an alternative, you can buy shares in several mutual funds focused on oil and gas, or ETFs. This will help you get significant information about the product without taking a direct risk in the wholesale prices of goods and without tying too much of your fortune to the prospects of any company.
2. Large stock of shares or American Depositary Receipts (ADRs).

These are two methods of gaining access to the oil and gas markets, both through exchange-traded companies, the most obvious is Exxon-Mobile (NYSE: XOM), one of the largest companies in the world measured by market capitalization. You can buy shares of British, Chinese, Russian and other oil and gas companies. Each of these companies is engaged in oil exploration and gain direct access to them by purchasing shares or ADRs (American Depositary receipts) from their broker.

3. Futures contract.

Purchasing futures contracts for oil and gasoline; however, this can be risky, because futures contracts can expire with no value.

4. Small or microprocessor-based shares and partnerships with limited liability.

You can take a direct equity position in a small for a company or project, you can think about developing the game down the "food chain" in the oil and gas industry into a small or micro—limited stock, or even a limited partnership that focuses on oil and gas.

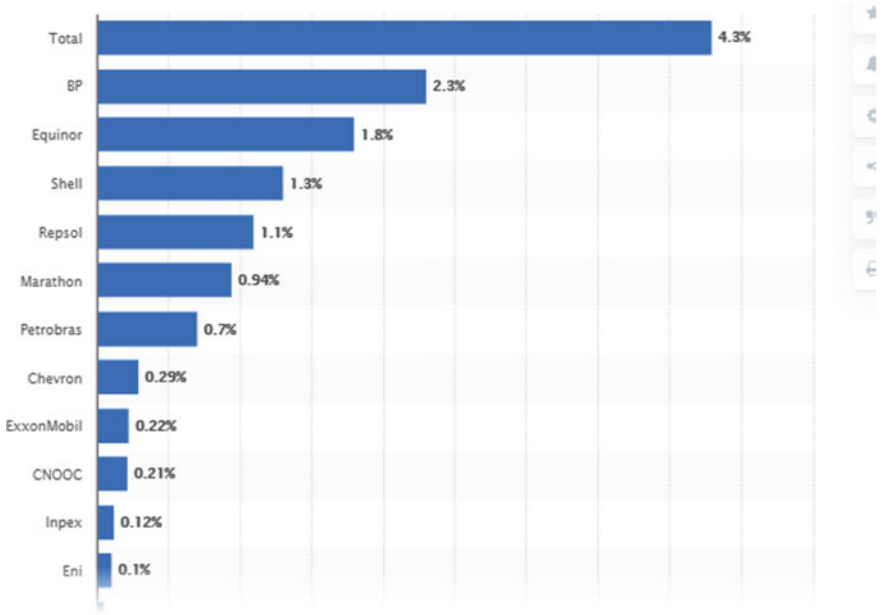

Fig. 1 Low-Carbon investments of leading oil companies world Cup 2010-2018 (share of total capital expenditures). Source: https://www.statista.com/statistics/1085091/low-carbon-investment-oil-companies-worldwide/

It's the more specialized sphere of investment, where you will need to use the services of a broker that specializes in this area. If you have a significant amount of money, then you can invest by contacting the company's management directly for the possibility of a private placement [1–4].

Figure 1 shows the low-carbon investments of the world's leading oil companies between 2010 and 2018 (as a share of total capital expenditures).

Figure 1 shows us that from 2010 to the third quarter of 2018, many large oil companies around the world have invested in renewable/low-carbon technologies. During this period, BP's low-carbon investments accounted for approximately 2.3% of its total capital expenditures.

Figure 2 shows the world's largest oil and gas companies by capital expenditures for development in 2013 Fig. 2 shows that in 2013, the world's largest oil and gas companies sent huge capital expenditures tools. Royal Dutch Shell plc spent on the development of around 26.5 billion USD.

Shell ranked fourth in terms of capital expenditure on development.

Types of oil and gas investments:

1. *Investigation.* Oil companies or projects buy or rent land and invest in drilling. If they produce oil, the investment can pay off 10 times—sometimes much more if the company uses borrowed funds to finance operations. If it's not, they can

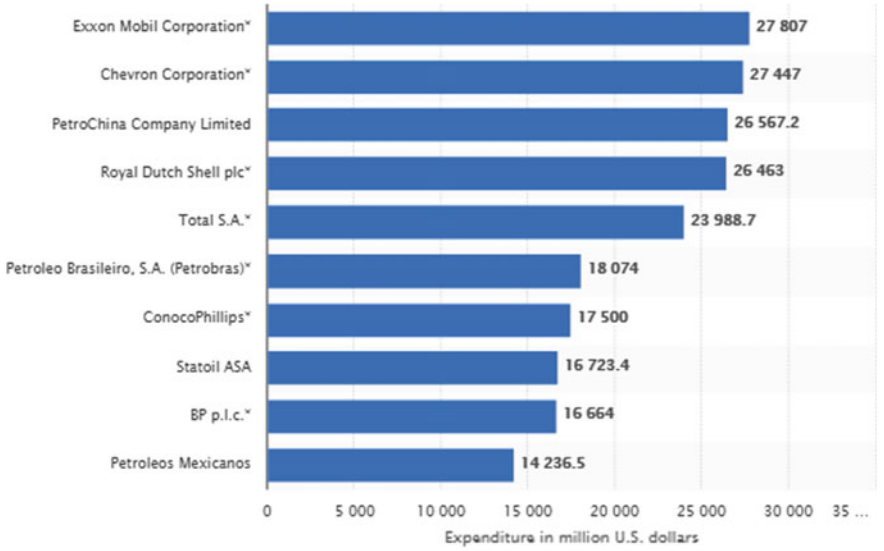

Fig. 2 The world's largest oil and gas companies by capital expenditures for development in 2013 (in millions of USD). Note: developed by the authors based on data https://www.statista.com/statistics/1085091/low-carbon-investment-oil-companies-worldwide/

lose almost everything they've invested in the project. Exploration companies are best suited for those who have very high resistance to investment risk.

2. *Development.* The projects explore close to the explored one's stocks in the hope of getting additional value, but there is no guarantee that their efforts on any piece of land bear fruit.
3. *Revenue.* Projects include the acquisition of land, either by lease or purchase, with proven oil and gas supply and seek to create a steady stream of income over expenses. It is considered as the safest way to take part in drilling and production operations, because of a speculative game. However, the risk is that oil or natural gas will run out faster. These investments are intended for those who are looking for a passive income, but who can take on more risk than those who invest in other traditional sources of income, such as investment-grade bonds and annuities.
4. *Services and support.* Oil companies provide an unlimited menu of support services for the oil and gas industry. For example, transportation, and logistics companies, pipeline companies, construction and rigging companies, manufacturers of equipment and equipment for drilling and processing, processors, and many others.

Investing in companies is similar to investing in any other company that provides B2B services, logistics, technology, etc. Some of these investments do not depend on higher fuel prices to be profitable. For example, pipelines make money by charging for a barrel of transportation. They will be about the same amount regardless of whether fuel prices rise or fall, as long as demand remains constant [5–7].

Let's look at the advantages and disadvantages of oil and gas investments.
Advantages:

1. *Diversification.* Oil and gas investments have historically provided diversification to the economy. When gas prices rise, the economy tends to slow down, which can cause the rest of the inventory and funds to stumble. But when oil and gas prices rise, supply rises with them. Exposure to oil and gas supply can help protect you from the economic downturn caused by oil shocks.
2. *Profit potential*. Investments in small companies and limited partnerships can sometimes pay off. One well can increase its value many times if drillers break through the oil, and the well can pay dividends for many years.
3. *Tax advantage*. There are some tax advantages to investing in oil and gas. For example, it allows companies to deduct for depletion—a method of accounting for the gradual depletion of mineral reserves in a given area. If you purchased stocks of publicly traded shares, this benefit will be invisible to companies, because shares of public corporations do not pass their profits and losses on the shareholders' tax returns [8–10].

Disadvantages:

1. *Volatility.* Oil and gas investments can be subjected to sharp price fluctuations, especially if you're investing in small companies. If you take part in exploration (wild) drilling projects, you can easily lose a large amount of money. Diversification is the key to investing in oil and gas. Losses of 50% or more are not unusual, and you can lose it on any project.
2. *Liquidity*. While it is usually possible to sell stock in larger companies, it is difficult to find a buyer for stocks in smaller companies. Sometimes, you might have to buy out your interest directly from a limited liability company or partner, it's often happening with closed, non-public companies and limited liability partnerships.
3. *Commission.* When you buy a limited liability company or closed Corporation, you usually pay a commission to a broker or intermediary. These commissions are much higher than standard stockbroker commissions and can exceed 20% for illiquid companies.
4. *Complexity*. Interest in oil wells and other oil and gas projects is not for everyone. Abroad, there are special tax rules governing investments in oil, gas, and minerals, and there are rules specific to limited partnerships that may affect the consideration of stocks at the sale.

Thus, oil and gas investments give accredited investors the opportunity to diversify their portfolio and generate large monthly cash flows, while taking advantage of significant tax incentives allowed by the US government. Each investor receives a share in the constant stream of profits generated from their owned wells, also known as a percentage of net income (NRI). In the worst-case scenarios, rarely when exploration hits a dry well, investors can recoup their investment in a 100% write-off of losses [4, 5, 9, 11] (Rudyk,2019, Kurmankulova,2019).

4 Conclusion

Consequently, the importance of oil and gas investment opportunities for companies is important today. As oil and gas drive the global economy, and in the absence of better alternatives, demand is expected to grow exponentially in the coming years. Global oil consumption expected to reach 119 million barrels per day by 2040. Thus, investments in oil and gas allow investors to receive long-term and stable income from their investments.

Investments in oil wells are less susceptible to economic downturns compared to reserves and other liquid investments. Thus, the US Government allows significant tax exemptions on the investments, makes them the most profitable option for accredited investors, which leads to more people with high income and accredited investors turning to the investment channel.

Problems of Digitalization of Fiscal Authority in Passenger Traffic

Anatoliy V. Zubach, Tatyana A. Lakhtina, and Lyubov S. Komovkina

Abstract The introduction of a new procedure for fiscal settlement in the field of public transport is, of course, a necessary tool for more complete accounting of funds and contributes to the transparency of the passenger transport market. However, according to the authors, the current legislation does not allow using most of the modern features, mechanisms and scenarios of passenger service that have already been implemented on public transport, which makes it necessary to analyze the existing problems from a legal point of view. The authors draw conclusions about the problems of legal regulation and law enforcement in the use of digital technologies when using cash registers in the process of passenger transportation and suggest possible ways to resolve them. This article undertakes the attempt to expand the knowledge about legal understanding of such important for the implementation of fiscalization calculations by public transport terms as the calculation date and the time of calculation, influencing the implementation of nonapologetic about application cash register technics, and also offers the best for the enforcers, the order of execution of requirements of the law and is addressed not only to researchers in the field of administrative, financial and information law, but the lawgiver and law-as applied.

E. G. Popkova et al. (eds.), *Socio-economic Systems: Paradigms for the Future*,
Studies in Systems, Decision and Control 314,
https://doi.org/10.1007/978-3-030-56433-9_71

use of cash registers in settlements in the Russian Federation" introduced novels affecting the interests of representatives of various sectors of the economy. Moreover, according to the Federal Tax Service of Russia, giving explanations on the application of the provisions of the law, the goals of Federal Law No. 54-ФЗ are to ensure the interests of citizens and organizations, protect consumer rights, ensure the established procedure for settlements, and ensure that revenue is fully accounted for in organizations and individual entrepreneurs, including for tax purposes and ensuring the established procedure for the circulation of goods.[1]

From July 1, 2018, cash registers included in the relevant register are used on the territory of Russia by all organizations and individual entrepreneurs when they make payments without fail, with the exception of cases established by paragraph 1 of Article 1.2. Federal Law No. 54-FZ.

Starting July 1, 2019, Federal Law dated July 3, 2018 No. 192-ФЗ "On Amending Certain Legislative Acts of the Russian Federation"[2] paragraph 4 of clause 2 of Article 2 is invalidated (*exceptions for the sale of travel documents inside the vehicle*) in the passenger compartment of the vehicle travel documents (tickets) and coupons for travel in public transport should be carried out using cash registers.

Innovations gave rise to a complex of problems caused by the specifics of the operation of public transport related to the implementation of the provisions of the law and the inability to fully ensure its implementation.

So, in the overwhelming majority of the constituent entities of the Russian Federation, there is no stable communication in public transport that can provide an immediate exchange of information during calculations, including for the purpose of fulfilling the requirements for providing a QR code with fiscal data, in connection with which it is time to provide a QR code for the screen of the computer device of the user (carrier) can be up to several minutes, which will lead to an increase in the time of landing passengers and the time the vehicle follows the route.

Lack of communication will also not technically allow the transfer of information about such a settlement to the tax authorities through the fiscal data operator at the time of calculation, and thus will serve as a reason for applying liability measures to the carrier [1–12].

In addition, the need to create a cashier's check in the absence of communication impedes the development of the functionality of modern payment systems, including the usual discounts for a passenger during transfers during a certain time from one route or type of transport to another, as well as the use of a national payment card system as a social card. MIR without recording on these cards special applications and data not provided for in the format of the banking application of MIR cards.

Delays in passenger service and a decrease in the quality of service will result in lower revenues of transport companies and will inevitably lead to higher tariffs and,

[1] See: Letter of the Federal Tax Service of Russia dated 10.12.2019 No. ED-4-20/ 25384 @//reference and legal system "Consultant Plus".

[2] See: Federal Law of 03.07.2018 No. 192-ФЗ "On Amending Certain Legislative Acts of the Russian Federation" Collection of Legislation of the Russian Federation, 07.07.2018, No. 28, Art. 4156.

consequently, costs of municipal and regional budgets, which reimburse carriers the lost revenue from transportation of privileged categories of citizens and losses from economic activities for municipal and state enterprises.

A partial solution to these problems was the so-called cloud fiscalization with the delayed provision of a fiscal check on the website of an authorized organization (fiscal data operator (hereinafter—CRF) or the Federal Tax Service) at the request of the passenger (buyer), for which information is posted on the ticket to identify this fiscal check on the website of an authorized organization. So, introduced by the Federal Law of June 6, 2019 No. 129-FZ "On Amendments to the Federal Law "On the Use of Cash Register Machines in Settlements in the Russian Federation",[3] clause 5.9 of Article 1.2. Federal Law No. 54-FZ, the right of the carrier, when making payments for public transport in the passenger compartment of the vehicle, to fulfill the obligation to send the cashier's receipt to the buyer by providing tickets to the buyer on paper with information sufficient for identification and free receipt by the buyer using information resources of the fiscal data operator or tax authority posted on the Internet, cash receipt (strict reporting form) in electronic form, which must be formed on the day of settlement.

The introduction of this norm allows the carrier to fulfill the requirements of Law No. 54-FZ, while optimizing its costs in comparison with the standard scheme for issuing cash receipts.

However, the implementation of these laws in the field of passenger transport by road causes certain difficulties due to the specifics of the functioning of the transport industry.

1. (a) Payment day. The operational transport day for passenger service does not coincide with the calendar day. The transport day starts later than 0.00 h and ends after 24.00. At this time, passengers are transported, cash is accepted on board vehicles, reporting documents for the shift are prepared, including registers of trips made for settlements. Accounting for this specificity will allow the user (carrier) to generate cashier's checks before the end of the settlement day, in other words, will enable the vehicle to return to the park and unload transport transactions from the terminal equipment for the preparation of cashier's checks. To implement this norm in the field of public transport, it is necessary to determine the transport operating day during the settlement day, during which the carrier accepts funds (settlement) for transportation services. Given the regional specifics, the boundaries of the transport day may vary, so they must be fixed in the contract with the client (passenger) or in the regional transportation rules, as well as the internal regulatory document for the carrier. The establishment of a different settlement day (for example, in accordance with the calendar) will lead to the fact that a significant part of the settlements will be carried out in violation of the requirements of the law, for example, with the planned arrival of the vehicle in the park and unloading transactions for the current day after 24.00 (actually after the end of the settlement calendar day)

[3] "Collection of Legislative Acts of the Russian Federation", 06/10/2019, No. 23, Art. 2912.

(b) The moment of payment. Cashless payments in the field of public transportation differ from standard payments in trade and service enterprises. In case of cashless payment, payment is not authorized at the time the card is attached to the terminal, but later ("suspended" authorization). At the time of applying the card, the terminal records only the fact of the trip, having previously checked the card for absence in the "stop list" loaded in the terminal. In the absence of high-quality online communication and the need to ensure high speed of passenger service, the credit institution checks for the availability of necessary funds later (after uploading by the transaction terminal). A credit institution, having received information about the need for settlement, provided that the client's account opened with a credit institution has sufficient funds or electronic banking funds authorizes (confirms) the settlement or, in case of insufficient funds, refuses to authorize the settlement. Only after that, funds for authorized transactions are sent to carriers.

In this regard, it is possible to guarantee that the carrier receives money for the trip (settlement) only after receiving authorization from the credit institution and the moment of settlement (and accordingly the settlement day) for cashless payments in public transport, it is possible to determine the moment of authorization. This approach will comply with paragraph 3 of Article 16.1 of the Federal Law of February 7, 1992 No. 2300-1 "On the Protection of Consumer Rights",[4] as well as the approach of the Ministry of Finance of the Russian Federation, cited in a letter dated April 6, 2018 No. 03-01-15/22629.[5]

However, to the maximum extent possible, the current practice of settlements in the field of public transport will correspond to the recognition by the moment of calculating the moment of finality of the transfer of funds in accordance with part 9, 10 of Article 5 of Federal Law of June 27, 2011 No. 161-FZ "On the National Payment System",[6] since at present information from the acquirer bank is received by a unified register for all payments for a business day in an automated payment system, after which the carrier is allocated money.

2. Providing a cash receipt to a customer. Federal Law No. 54-FZ makes it possible, for the purpose of providing a cashier's check, to indicate on the ticket information (hereinafter the "Information") sufficient for identification by the buyer (client) and using it free of charge using the information resources of the Fiscal data operator (FDO) or the tax authority posted in the Internet.

Three options for implementing this requirement are possible:

1. The use of ticket details as Information approved by Decree of the Government of the Russian Federation dated February 14, 2009 No. 112 "On the Approval of the Rules for Passenger and Baggage Transportation by Road Transport and Urban Electric Land Transport",[7] which provided for several forms of ticket.

[4] "Collection of Legislative Acts of the Russian Federation", 15/01/1996, No. 3, Art. 140.

[5] Reference and legal system "Consultant Plus".

[6] "Collection of Legislative Acts of the Russian Federation", 04/07/2011, No. 27, Art. 3872.

[7] Collection of Legislative Acts of the Russian Federation", 02/03/2009, No. 9, Art. 1102.

The identifying details of the trip and calculation may be: the ticket, its name, series, number issued by the organization, type of vehicle transporting, ticket price.

Having a ticket and information about the FDO, the passenger on the FDO website by indicating these data is given the opportunity to receive a cash receipt in electronic form.

The disadvantages of this scenario are:

– a complex user scenario—the need for accurate and accurate introduction of a large amount of information (risk of mistake);
– a high degree of integration with the FDO is required (the inclusion of a significant additional amount of information in the transferred fiscal data).

2. The use of a special code indicated on the ticket as the Information that ensures the uniqueness of the calculation information generated by the automated system.

Having a ticket and information about FDO, the passenger on the FDO website by specifying a special code gets the opportunity to receive a cash receipt in electronic form, which greatly simplifies the user scenario.

The disadvantage of this scenario is the lack of support for using traditional ticket roll products.

3. Use as information of standard data necessary for checking a check in the mobile application of the Federal Tax Service of Russia.

The implementation of this scenario also provides for the formation in the automated fare payment system by the terminal when printing a ticket of a unique code for each calculation, containing a link to the website of the automated system, where it is saved along with the calculation information. After the formation of a cash receipt, fiscal data is added in an automated system to a unique code. The client, entering a unique code on the operator's site of the automated system, is redirected to the site of the fiscal data operator that processed this calculation, while the identifier is not a unique code, but ready-made fiscal data, according to which the client will receive a cash receipt in electronic form in the standard manner.

This scenario has the greatest potential for standard use in all regions and its implementation does not require improvements on the side of the FDO or the Federal Tax Service of Russia, as well as special technical integration with FDO.

In view of the requirements of Federal Law No. 54-FZ, which are set out to fulfill the requirements, it is necessary to normatively regulate the concepts of settlement day, settlement moment, and determine methods of sending a cash receipt to a client for their implementation in passenger transportation in the Russian Federation.

Uniform Approximations to Solutions of Singularly Perturbed Systems of Differential Equations with the Eigenvalues Which Have No Zero in the Region Under Consideration

Saly K. Karimov and Guljamal M. Anarbaeva

Abstract This article is reporting study of the solution for a singularly perturbed nonlinear system of differential equations. In this paper, solutions of a singularly perturbed nonlinear system are considered in a particularly critical case. The matrix of a linear system has complex conjugate eigenvalues. The eigenvalues of the matrix of the system under consideration do not have zeros on the boundary of the region under consideration and outside this region, and the imaginary parts of the eigenvalues of the matrix are positive with the exception of boundary points in the considered domain. A uniform approximation was constructed for the solution of the initial Cauchy problem in a particularly critical case with any degree of accuracy. Results were also obtained for a specific task.

Keywords Singularly perturbed system of differential equations · Initial cauchy problem · Solution · Eigenvalues of a matrix · Asymptotic · Critical case · Uniform approximations

1 Introduction

A singularly perturbed differential equation can be defined as an ordinary differential equation in which the highest order derivative is multiplied by a small parameter known as perturbation parameter, for which solution varies rapidly in the regions called as layers which may be apparent in the solution or its derivatives [1].

Previously the existence of a solution defined for all t and possessing a type of boundedness property was established for the perturbed nonlinear system $y = f(t, y) + F(t, y)$ [2]. Singularly perturbed differential algebraic equations have been studied through the asymptotic expansion of outer solutions [3]. An asymptotic

stability of solutions for a linear singularly perturbed system with unbounded delay have been reported, where local Lipschitz initial function was applied for degeneration of the initial value problem for the system [4]. The boundary-value problems (BVPs) for singularly perturbed nonlinear differential equations also reported [5]. One-parameter family of matrices with distinct eigenvalues [6], and the use of Tau-Collocation method for the numerical approximation of eigenvalues [7] were considered for differential equations. Multi-order fractional differential equations transformed into a system of nonlinear algebraic equations in matrix form by the help of Tau-Collocation method have been studied [8].

Here we report uniform approximations to solutions of singularly perturbed systems to differential equations with the eigenvalues which have no zero in the region under consideration.

2 Statement of Problem

The problem under consideration is as follows:

$$\varepsilon x'(t,\varepsilon) = D(t)x(t,\varepsilon) + \varepsilon[f(t) + B(t)x(t,\varepsilon)] + g(t, x(t,\varepsilon)), \tag{1}$$

$$x(t_0,\varepsilon) = x^0(\varepsilon),\ \left\|x^0(\varepsilon)\right\| = O(\varepsilon), \tag{2}$$

where $D(t) = diag(\lambda_1(t), \lambda_2(t))$; $f(t) = colon(f_1(t), f_2(t))$; $B(t) = \left(b_{jk}(t)\right)_1^2$; $g(t, x(t,\varepsilon)) = colon(g_1(t,x), g_2(t,x))$, $g(t,0) \equiv 0$;

$\varepsilon > 0$—small parameter; $[t_0, T_0]$—segment of the real axis, $t_0 < T_0$;

$$H_0 = \{(t_1,t_2) : t_0 \le t_1 \le T_0,\ -\infty < t_2 < +\infty\} \subset S$$
$$= \{(t_1,t_2) : t_0 - \gamma < t_1 < T_0 + \gamma,\ -\infty < t_2 < +\infty,\ 0 < \gamma << 1\};$$
$$\Delta(t,x) = \left\{(t,x) = (t,x_1,x_2) : t \in S;\ \left|x_j\right| < \delta\ (j = 1,2),\ 0 < \delta - const\right\};$$

$\Phi(S)$—space of analytic functions in S.

We seek the solution $x(t,\varepsilon) = colon(x_1(t,\varepsilon), x_2(t,\varepsilon))$ in the class $x_k(t,\varepsilon) \in \Phi(S)$ $(k = 1,2)$ in t.

Let: I. $\lambda_k(t) \in \Phi(S)$; $f_k(t) \in \Phi(S)$; $b_{kj}(t) \in \Phi(S)$; $g_k(t,x) \in \Phi(\Delta(t,x))$ $(k, j = 1,2)$;

In the area $\Delta(t,x)$ takes place $||g(t,x) - g(t,\tilde{x})|| \le M||x - \tilde{x}||\ (\max\{||x|, |\tilde{x}||\})^{\beta}, M > 0, \beta \ge 1$,

II. $\lambda_1(t) = \alpha(t) + i\beta(t)$, $\lambda_2(t) = \alpha(t) - i\beta(t)$, where $\alpha(t)$, $\beta(t)$—real functions, and $\alpha(t) < 0$ at $t_0 \le t < a_0$; $\alpha(t) > 0$ at $a_0 < t \le T_0$, $\alpha(a_0) = 0$, but $\beta(a_0) \ne 0$.

$t = t_1 + it_2$, $\tau = \tau_1 + i\tau_2$, где t_1, t_2, τ_1, τ_2—real variables;

$$u_k(t_1, t_2) = \mathrm{Re} \int_{t_0}^{t} \lambda_k(s)ds (k = 1, 2);$$

$$H_0 = \{(t_1, t_2) : u_k(t_1, t_2) \leq 0,\ k = 1, 2\};$$

$u_1(t_0, t_2) = u_1(T_0, t_2) = 0$ at $-\infty < t_2 < +\infty$.

III. Eigenvalues have no zeros on the boundary of the region and outside the region, and $\mathrm{Im}\lambda_k(t_1, t_2) > 0$ with the exception of the boundary points H_0. We assumed the existence of a line-level $u_1(t_1, t_2) = C \leq 0$ connecting all points of the segment $[t_0, a_0)$ with some segment of $(a_0, T_0]$.

First, the problem (1), (2) was replaced by the following equivalent problem:

$$x(t, \varepsilon) = E(t, t_0, \varepsilon)x^0(\varepsilon) + \int_{t_0}^{t} E(t, \tau, \varepsilon)[B(\tau)x(\tau, \varepsilon) + f(\tau)]d\tau$$

$$+ \frac{1}{\varepsilon} \int_{t_0}^{t} E(t, \tau, \varepsilon)g(\tau, x(\tau, \varepsilon))d\tau, \tag{3}$$

where $E(t, \tau, \varepsilon) = \exp\left(\frac{1}{\varepsilon} \int_{\tau}^{t} D(s)ds\right)$.

According to our previous works, we recursively defined the following functions:

$$x^{(0)}(t, \varepsilon) \equiv 0,\ x^{(1)}(t, \varepsilon) = E(t, t_0, \varepsilon)x^0(\varepsilon) + \int_{t_0}^{t} E(t, \tau, \varepsilon) f(\tau)d\tau;$$

$$x^{(k+1)}(t, \varepsilon) = \int_{t_0}^{t} E(t, \tau, \varepsilon)B(\tau)x^{(k)}(t, \varepsilon)d\tau$$

$$+ \frac{1}{\varepsilon} \int_{t_0}^{t} E(t, \tau, \varepsilon)\left[g(\tau, X^{(k)}(\tau, \varepsilon)) - g(\tau, X^{(k-1)}(\tau, \varepsilon))\right];$$

$$X^{(k)}(\tau, \varepsilon) = \sum_{m=0}^{k} x^{(m)}(t, \varepsilon). \tag{4}$$

Then the solution of problem (1), (2) can be represented as:

$$x(t, \varepsilon) = x^{(1)}(t, \varepsilon) + x^{(2)}(t, \varepsilon) + \cdots + x^{(k)}(t, \varepsilon) + \cdots \tag{5}$$

Here $x^{(1)}(t, \varepsilon)$ is determined as a first approximation of Eq. (3), and $x^{(k)}(t, \varepsilon)$ $(k = 2, 3, \ldots)$ is sequentially determined by Eq. (4).

3 Solution of the Problem

Now the problem is that how to build a majoring series coming down to a series of functions (5) at $0 < \varepsilon \le \varepsilon_0 - const$; $t \in H_0$.

From previous results it follows that $\lim_{t_2 \to -\infty} u_1(t_1, t_2) = 0$ $\left(\lim_{t_2 \to +\infty} u_2(t_1, t_2) = 0\right)$ or $\lim_{t_2 \to +\infty} u_1(t_1, t_2) = 0$ $\left(\lim_{t_2 \to -\infty} u_2(t_1, t_2) = 0\right)$ at a fixed t_1.

Let $\{C_1\}$ $(u_1(t_1, t_2) = C_1)$ connect points, $(t_{01}, 0)$, $(T_1, 0)$, and $\{C_2\}$ $(u_1(t_1, t_2) = C_2)$ points $(t_{02}, 0)$, $(T_2, 0)$ $(t_0 < t_{01} < t_{02} < a_0,\ a_0 < T_2 < T_1 < T_0)$,

We will consider the line P bounded by the curves of the levels $\{C_1\}$ and $\{C_2\}$ and segments of the real axis $[t_{01}, t_{02}]$, $[T_2, T_1]$..On the line P we will consider the equations

$$u_1(t_1, t_2) = at_1 + b, \text{ где } a = \frac{C_2 - C_1}{T_2 - t_{01}}, \mathrm{b} = \frac{C_1 T_2 - C_2 t_{01}}{T_2 - t_{01}}. \tag{6}$$

The main lemma: If level lines $u_1(t_1, t_2) = C$ $(C_2 \le C \le C_1)$ completely cover line P and an arbitrary point (t_1, t_2) line P belongs to a single line-level $\{C\}$, $Jm\lambda_1(t) \ne 0$, then equations (6) in the line P defines valued continuously differentiable function $t_2 = \varphi(t_1)$ with the region of existing of $(t_{01} \le t_1 \le T_2)$ and the curve segment (K_0), defined by this function, connects points $(t_{01}, 0)$, $(T_2, 0)$, and at this $\mathrm{u}_1(t_1, \varphi(t_1))$ is decreasing on $[t_{01}, T_2]$.

The main lemma was proved with an original method. Another proof is available in our papers.

Let $\alpha(\varepsilon)$ be defined, continuously and monotonically decreasing on the interval $0 \le \varepsilon \le \varepsilon_0$, and at $\alpha(0) = 0$.

Then from the equality $u_1(t_1^*, 0) = \alpha(\varepsilon)$ (7) in a neighbourhood of the point $(t_1^* = t_0, \varepsilon = 0)$ is uniquely determined $t_1^* = t_0 + \gamma(\varepsilon)$, and, $\lim\limits_{\varepsilon \to 0} \gamma(\varepsilon) = 0$, where $\gamma(\varepsilon) \ge 0$ continuous function from ε at $0 \le \varepsilon \le \varepsilon_0$. Similarly, from (7) in a neighbourhood of $(t_1^* = T_0, \varepsilon = 0)$ is uniquely determined $t_1^* = T_0 - \tilde{\gamma}(\varepsilon)$, where $\tilde{\gamma}(\varepsilon) \ge 0$ is a continuous function from ε at $0 \le \varepsilon \le \varepsilon_0$, and $\lim\limits_{\varepsilon \to 0} \tilde{\gamma}(\varepsilon) = 0$. Let's take the curve (K_0^*) symmetrical to (K_0). Area bounded (K_0) and (K_0^*) we will mark by $H \subset H_0$. $\tilde{H} = \Delta \cup H$, where $\Delta = \{(t_1, t_2) : t_0 \le t_1 \le t_{01}, t_2 = 0\}$. And now we will value $x_1^{(n)}(t, \varepsilon)$ $(n = 1, 2, \ldots)$ for $\forall t \in \tilde{\mathrm{H}}$.

For all functions $x_1^{(n)}(t, \varepsilon)(n = 1, 2, \ldots)$ the path of integration of l will be constant. There is also the path of integration of l that is determined depending on which set the point belongs (t_1, t_2). If $(t_1, t_2) \in \Delta(t = t_1, t_2 = 0)$, then l consists of one segment of linear segment, connecting the point $(t_0, 0)$ with the point $(t_1, 0)$ $(t_0 \le t_1 \le t_{01})$. In this case $\mathrm{Re}\ \lambda_k(t) \le -\alpha, \alpha > 0 - \mathrm{const}$.

Let $(t_1, t_2) \in H$. Then $l = \bigcup_{k=1}^{3} l_k$, where l_1—linear segment, connecting the points $(t_0, 0)$ with the point $(t_{01}, 0)$; l_2—curve segment (K_0), connecting the points $(t_{01}, 0)$ with the point (t_1, t_2^*); l_3—linear segment, connecting the points (t_1, t_2^*), with the point (t_1, t_2). We will note that if $(t_1, t_2) \in H$, then the vertical line passing

through the point (t_1, t_2) intersects the curve (K_0) at the single point (t_1, t_2^*). Further the path of integration of l is determined as here.

For $x_2^{(n)}(t, \varepsilon)$ $(n \geq 1)$ the path of integration of l^* is symmetrical for l in respect to the real axis.

If $C_1 = -\delta_0, C_2 = -2\delta_0, \delta_0 - const,\ 0 < \delta_0 << 1$, then

$$\left| \int_l \exp \frac{1}{\varepsilon}[u_1(t_1, t_2) - u_1(\tau_1, \tau_2)]\, |d\tau| \right| = \mathrm{O}(\varepsilon). \tag{7}$$

The curve (K_0) connects the points $(t_0 + \beta, 0), (T_0 - \tilde{\beta}, 0)$ where $\beta > 0$ $(\tilde{\beta} > 0) - const$.

In this case the area bounded (K_0) and (K_0^*) we will mark by H_c and $\tilde{H}_c = \tilde{\Delta} \cup H_c$, where $\tilde{\Delta} = \{(t_1, t_2) :\ t_0 \leq t_1 \leq t_0 + \beta,\ t_2 = 0\}$.

If $C_1 = -\sqrt{\varepsilon}, C_2 = -2\sqrt{\varepsilon}$, than the curve (K_0) connects the points $(t_0 + \gamma_1(\varepsilon), 0)$, $(T_0 - \tilde{\gamma}_1(\varepsilon), 0)$. In this case the area bounded (K_0) and $\left(\mathrm{K}_0^*\right)$ we will mark by H_ε and $\tilde{H}_\varepsilon = \Delta_\varepsilon \cup H_\varepsilon$, where $\Delta_\varepsilon = \{(t_1, t_2) : t_0 \leq t_1 \leq t_0 + \gamma_1(\varepsilon);\ t_2 = 0\}$.

If $C_1 = \delta(\varepsilon),\ C_2 = 2\delta(\varepsilon), (\delta(\varepsilon) = \varepsilon \ln \varepsilon\ \ npu\ \ 0 < \varepsilon << \varepsilon_0 - const,\ \delta(0) = 0)$ than the curve (K_0) connects the points $(t_0 + \gamma_2(\varepsilon), 0), (T_0 - \tilde{\gamma}_2(\varepsilon), 0)$. In this case the area bounded (K_0) and $\left(\mathrm{K}_0^*\right)$ we will mark by K_ε and $\tilde{K}_\varepsilon = \tilde{\Delta}_\varepsilon \cup K_\varepsilon$, where $\tilde{\Delta}_\varepsilon = \{(t_1, t_2) :\ t_0 \leq t_1 \leq t_0 + \gamma_2(\varepsilon),\ t_2 = 0\}$

Here $\gamma_k(\varepsilon),\ \tilde{\gamma}_k(\varepsilon)$ $(k = 1, 2)$ have the same properties as the $\gamma(\varepsilon),\ \tilde{\gamma}(\varepsilon)$.

$$\text{The following estimates}(j = 1, 2; n = 1, 2, \ldots) : \left| x_j^{(n)}(t, \varepsilon) \right| \leq (c\varepsilon)^n \text{ at } (\mathrm{t}_1, \mathrm{t}_2) \in \tilde{H}_c \text{ and at } \beta \geq 1; \tag{8}$$

$$\left| x_j^{(n)}(t, \varepsilon) \right| \leq \left(c\sqrt{\varepsilon}\right)^n \text{at } (\mathrm{t}_1, \mathrm{t}_2) \in \tilde{H}_c \text{ and at } \beta \geq 2; \tag{9}$$

$$\left| x_j^{(1)}(t, \varepsilon) \right| = O\left(\frac{1}{|\ln \varepsilon|}\right) \text{ at } (\mathrm{t}_1, \mathrm{t}_2) \in \tilde{K}_\varepsilon, \tag{10}$$

where the constant c depends neither on n, nor on ε.

4 Main Results

Theorem Let conditions I, II, and III be completed. Then for the problem (1), (2) at $\tilde{H}_\varepsilon$ there is the only solution and the value is correct for it: (8) at $\tilde{H}_c$; (9) at $\tilde{H}_\varepsilon$.

5 Conclusions

As a result of this work, uniform approximations were constructed for the solution of a singularly perturbed system of differential equations in the especially critical case when the eigenvalues do not have zeros on the considered domain.

Digital Transformation of the Financial Services Market in Russia

Viktoria G. Makeeva, Sergey A. Nikitin, and Daria A. Elkina

Abstract The effectiveness of the digital transformation of the Russian economy is largely determined by its financial sector. In turn, in modern research, the issue of the influence of digitalization of the financial system on the entire value chain of financial services remains insufficiently studied, while at the same time facilitating the intensification and deepening of relations with customers. The article explores the features of digitalization of financial services associated with its intangible nature, heterogeneity of estimates. The methodological base of the study includes the theoretical principles of the digital economy and the concept of business models taking into account the specifics of the activities of financial organizations. Retrospective and prognostic research methods made it possible to identify the main tools for digital transformation of the financial services market: virtual banks; financial and technical companies; international and national electronic money systems; digital currency; online loans; payment services of IT platforms; crowdfunding and crowdinvesting; "End-to-end" digital technologies"; external electronic document management services. Based on the results of the study, a generalized conclusion was made about the existence of serious problems of a technical, economic and social nature, their dominance in the financial services market was noted along with existing economic problems. Recommendations have been developed to improve the regulatory framework that protects the interests of agents involved in creating the value of financial services. Scientific novelty is reflected by the proposed conceptual business model of digitalization of financial and credit institutions, the management areas of which may include: improving operational efficiency, introducing innovations (smart technologies), managing customer relationships, and ensuring structural flexibility ("bank as a network"). The theoretical and practical significance of the study lies in the fact

1 Introduction

Today, the formation of a new social order is associated with the development of the digital economy, which in the context of globalization of socio-economic processes contributes to the competitiveness of the country. This is one of the most important tasks of any state [1].

The digital economy, based on the digitization of information and the corresponding information and communication infrastructure, implies the emergence of not only technological, but also structural and process challenges and opportunities. This new type of economic relationship implies the emergence of technological, structural and process challenges and opportunities. Thus, the digital transformation of society is a complex process, one of the elements of which is the digitalization of the financial services market.

The digital transformation should be seen as..: "…something much more than just understanding and implementing new technologies. It stimulates a wave of innovations in business models, products, services and internal business processes that can threaten the survival of an organization. In addition to the use of new technologies, this requires new ways of thinking and doing business, new roles and skills, new organizational structures and operating models, and adapting to the much faster pace of change" [2].

The effectiveness of the functioning of digitalization processes, as well as of all sectors of the Russian economy and society, depends on the state of the financial system. The market of financial services promotes economic growth and innovation, and stimulates the introduction of science and technology to accelerate social reproduction.

Digitalization [3–6] of the financial system affects the entire value chain of goods, works and services, and the competitive position of the company [7]. This is confirmed by the data on revenue per employee (RPE) of such companies as Visa, Mastercard, PayPal (Fig. 1), where it is $1062 million, $906 million, $599 million respectively.

The importance of digital transformation of the financial sector is also demonstrated by the documents adopted by the Central Bank of Russia, in particular, "Action plan (road map) for implementing the Guidelines for the Development of the Russian Financial Market in 2019-2021" (approved by the Bank of Russia Board of Directors on 26 May 2018). According to analysts of the Accounts Chamber, the action

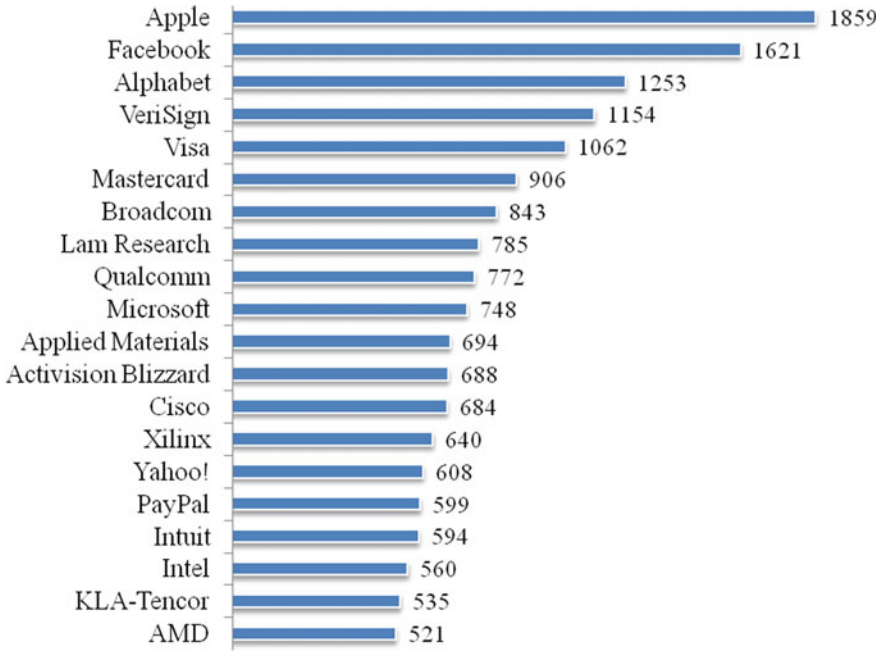

Fig. 1 Revenue per employee, in million USD. *Source* Compiled by the authors based on data [8]

plan ("road map") for the period 2016-2018 is fulfilled by 97.8% (Sawatjgin 2020). In addition, experts point to the subjective nature of a number of key performance indicators of measures set by the Central Bank of Russia (Sawatjgin 2020).

In this regard, the study of the specifics of digital transformation of the financial services market is an urgent task. The findings will help to formulate more clearly the problems of the process of digitalization of the financial sector and adjust, if necessary, the key performance indicators of measures to develop the financial market of Russia. In addition, this will provide the basis for monitoring the development of digital transformation of the financial sector, improving the management system of structural-digital institutions [1].

Besides, there are no assessment indicators specific to this sphere in the world practice. There are a number of international indices existing at the moment (Digital Opportunity Index, DOI; ICT Development Index; Networked Readiness Index, NRI; The UN Global E-Government Development Index; The Web Index (Internet Development); The Global Innovation Index; Information and communication technologies Development Index, IDI), which are primarily aimed at assessing the degree of digitalization of the economy as a whole [9].

The purpose of this study is to study the features of digitalization of financial services. The complexity of evaluation of digital transformation of financial market is connected with the peculiarities of financial service: intangible nature, heterogeneity

of evaluation, inseparable nature of production and consumption process, perishable nature. This is the concept of IHIP (intangibility, heterogeneity, inseparability, perishability), which is used in the sphere of services marketing [10–12].

2 Background and Methodology

The research methodology is based on classical methods of analysis and synthesis, induction and deduction, which allowed to reveal features and trends of financial services market development, to generalize empirical data on the state of development of the Russian financial market in the epoch of digital transformation.

The information base of the research was provided by the primary sources: statistical data of the World Bank and the Central Bank of the Russian Federation for the period from 2015 to 2019, materials of the Federal State Statistics Service (Rosstat), specialized reference legal system (database "ConsultantPlus"), official Internet resources of the state authorities (gov.ru). These sources were correlated with secondary information resources: case studies of leading scientists, materials from symposiums and scientific conferences. It allowed to increase completeness and representativeness of the data used for analysis, as well as to formulate problems of digital transformation of financial system.

3 Discussion and Results

Modern digital technologies allow to qualitatively increase realization of financial services among all subjects of financial sector.

The digital transformation of the financial services market is primarily manifested in such mechanisms and instruments as:

- virtual banks (Internet banking, E—banking);
- FinTech companies (FinTex);
- international and national electronic money systems (PayPal, M-Pesa);
- digital currency market (Bitcoin, Namecoin, PPCoin);
- online loans (Smartcredit, Moneza);
- payment services of IT platforms (X-Plat, PayU);
- crowdfunding and crowd investing (AngelList, EquityNet);
- end-to-end digital technologies;
- services of external electronic document circulation.

The intensity of digital transformation of the financial services market depends on the necessary and sufficient conditions of this process [9]. Consider some of these conditions in more detail.

Digitalization of financial services concerns forms of interaction of market participants with each other: personal contact gives way to remote electronic interaction.

For example, despite the reduction in the number of credit and insurance institutions in the market, they actively use the capabilities of the Internet to provide various services.

As can be seen from Fig. 2, post offices were actively involved in a number of banking operations, the growth rate of which was 103.9% compared to 2017. This success is primarily due to the introduction of modern IT systems [13]. In 2018, compared to 2017, the number of ATMs with the function of cash acceptance using payment cards (their details) increased by 1.4%; the number of electronic terminals (POS-terminals) increased by 18.3% (Fig. 3).

As for the subjects of insurance business (insurance organizations, insurance brokers), according to Expert RA rating agency, only 5% of respondents do not use Internet solutions when concluding insurance contracts (Skuratova and Yanin 2019). The types of insurance services provided in digital form are shown in Fig. 4.

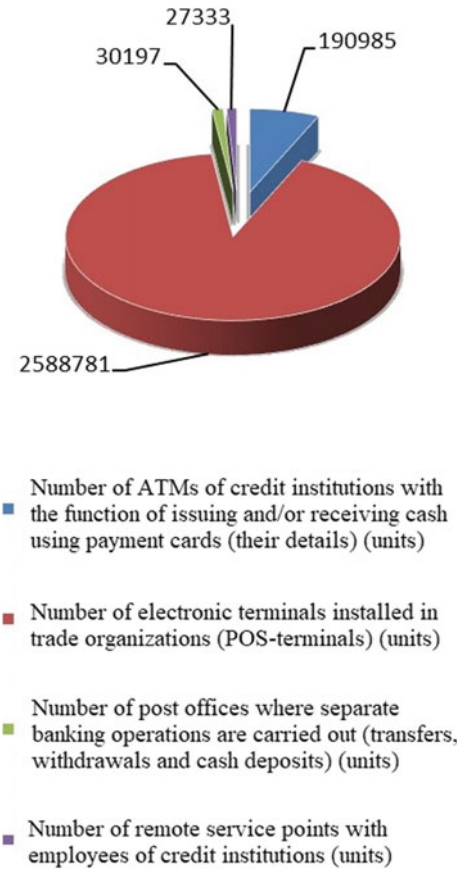

Fig. 2 Financial services availability indicators as of 1.01.2019. *Source* Compiled by the authors based on data from the Central Bank of Russia

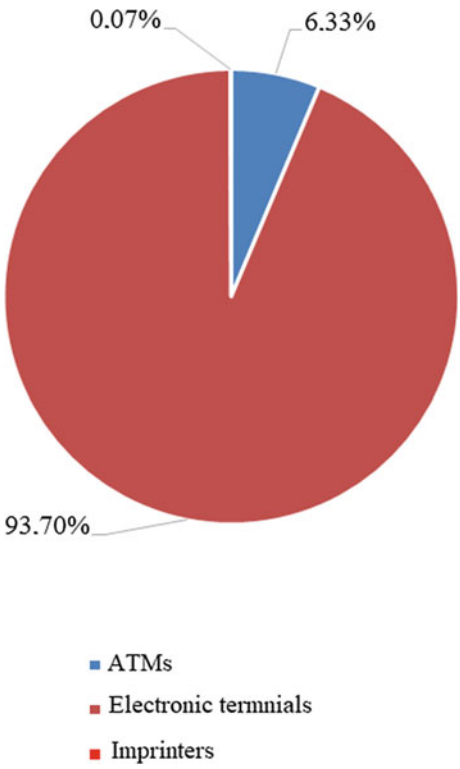

Fig. 3 Payment card reception equipment structure, 2018. *Source* Compiled by the authors based on data from the Central Bank of Russia

The infrastructure of the financial services market consists also of hardware and software. Figure 5 shows data on the use of ICT technologies in organizations by type of economic activity.

Analysis of the data in Fig. 5 shows that the share of companies in financial, insurance and educational activities is quite high in terms of usage: website on the Internet—66.7% and 87.9%; cloud services—30.1% and 43.8%; LAN (local area networks)—73.8% and 90.6%; personal computers—94.9% and 98.4% respectively.

It should be emphasized that sufficient conditions for digital transformation of the financial services market ensure their effective provision.

For example, the use of modern software by financial market companies increases the quality of provided services and expands their diversity. In 2012, the crowdfunding platforms Planeta.ru and Boomstarter were created in Russia.

In 2018, Planeta.ru implemented 2985 projects, 33% of which were successful, and the average check was 1.2 thousand rubles. In the same period, 787 projects were implemented on the Boomstarter platform, 49% of which are successful, and the average check amounted to 2000 rubles.

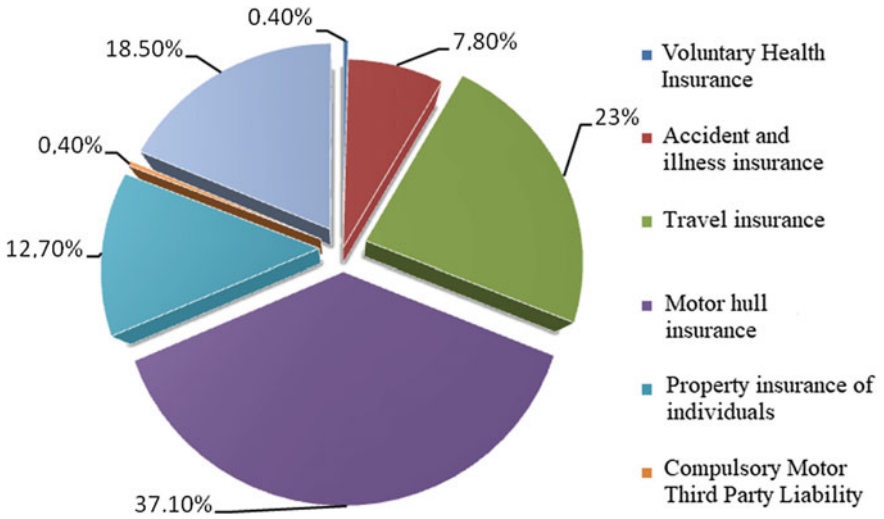

Fig. 4 Structure of electronic insurance by types without CMTPL insurance, 2018. *Source* Expert RA, according to the data of companies

In Russia, the mechanism of biometric remote identification has been used since June 2018. Registration in the Unified Biometric System allows for the storage and processing of biometric data for the implementation of remote identification of citizens, which is now available at 3,250 points of banking services in 61 banks and outside offices in all regions of the Russian Federation (courier model).

Development of the Russian financial services market is characterized by strengthening of supervising functions of the Bank of Russia, high competition in the relevant market segments and consolidation of participants. These factors change the number of participants in the financial and microfinance market.

From 2015 to 2020, there has been a decrease in the number of all categories of participants in the financial market: by 53.5%—credit organizations; 45.1%—insurance entities (insurers, insurance brokers). The number of consumer credit cooperatives and microfinance organizations dominating the market also decreased: from 3,226 to 1,525 credit unions and from 3,992 to 1,774 microfinance organizations. Non-State pension funds, the number of which stood at 120 in 2015, reached 47 in 2020. An exception to this trend is collection agencies, the number of which increased from 177 to 294 in the period from 2018-2020.

At the same time, new participants appear on the financial services market: investment advisors, forex dealers and operators of investment platforms. As of 10.01.2020, the unified register of the Bank of Russia includes 69 investment advisors, 4 companies have a license of a forex dealer.

Thus, it's unlikely that any other industry will encounter such persistent digitalization challenges as the financial industry. The model presented in Fig. 6 is proposed

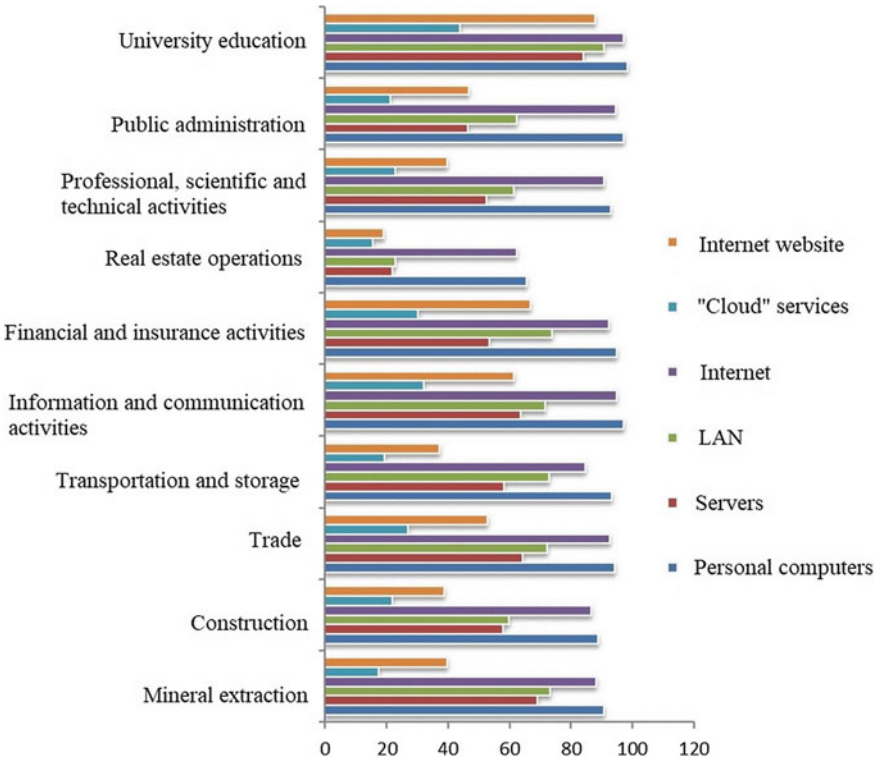

Fig. 5 Share of ICT companies (as of 2017). *Source* Compiled by the authors on the basis of data from the Federal State Statistics Service

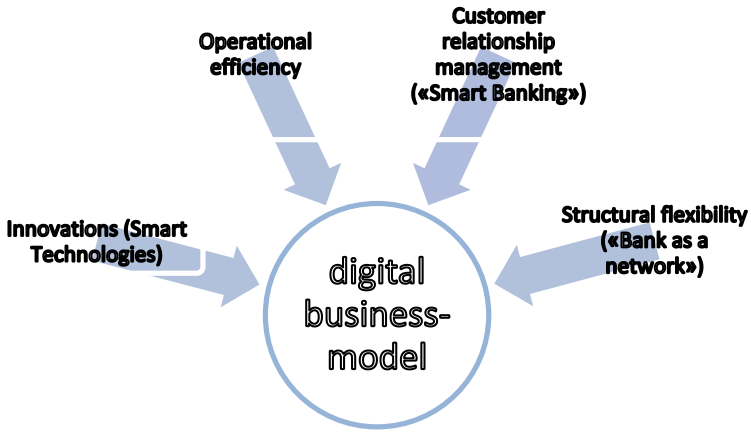

Fig. 6 Model of a financial institution standard 4.0. *Source* Compiled By the authors

to adapt existing business models to the requirements of the digital transformation of the financial services market.

The presented business model includes the key factors affecting digitalization in the banking business of the future and the requirements arising from these processes for the technological infrastructure of the financial sector.

The digital model of a financial institution includes the following areas of management:

- operational efficiency (digitization of work processes; acceleration of key processes through the use of Front office/back office; automation of functional efficiency (Controlling, Reporting, Risk Management), to increase which there are provide a flexible and scalable IT infrastructure, replacing obsolete systems with modular basic banking systems; use of cloud architectures, SaaS, PaaS; integration of ERP, BPM, DMS through standardized APIs; use of DLT (Distributed ledger technology)/Blockchain;
- customer relationship management (development of Omni-channel concepts and individual products; Customer Profiling und Tracking; Customer Life Cycle Management; Corporate & Investment Banking), the effectiveness of which provides for a service-oriented architecture (SOA), solutions for mobile banking (applications for wallets, personal finance tools, Robo Advisors), predictive analytics/business analytics (social networking tools, artificial intelligence, data science, virtual/augmented reality), use of DLT/Blockchain;
- innovations (innovative products/services, for example, instant payments, Robo Advisory, Smart Securities, Smart Credit; applications for Trade Finance, syndicated loans; reducing the time to market for new financial products; simple integration of third-party applications), the implementation of which involves the using of the platform for blockchain solutions/distributed registries; smart contracts; solutions for high-performance computing (LDCs), the using of data science, artificial intelligence, machine learning for new investment strategies, loan portfolio management, market risk management;
- structural flexibility (reduction of value added by focusing on core activities (outsourcing, offshoring), the using of networks with partners in sales and production to create value), which can be achieved through a flexible, scalable, open system architecture to unite new customers, service providers (Fintechs), improved regulatory compliance (RegTech), simplified networking and cloud-based networking, and the using of DLT/Blockchain.

The discussion on digitalization in banks often comes down to automating processes and the associated cost reduction or efficiency gains. The real challenges for digital banks will be to provide customers with innovative, personalized and intelligent services and, thus, transform traditional customer relationship management into an intelligent banking approach in the medium and long term.

The successful implementation of digitalization processes in Russian society depends not least of all on legislative and regulatory aspects of this issue. In the program “Digital Economy of the Russian Federation” approved by the Order of the Government of the Russian Federation from 28.07.2017 No. 1632-r for the period up

to 2025, special attention is paid, inter alia, to legal issues of digital transformation as a necessary condition for digitalization of the financial services market.

Introduction of innovative financial technologies and services is ahead of the system of their legal regulation, in particular, protection of rights of people developing and using digital technologies is not effective. According to experts, "in 2014–2018 the courts considered 148 such cases. Of those, 45% were related to the performance of obligations under smart contracts, as well as the recognition of the cryptocurrency as an object of civil circulation. At the same time, not a single case was resolved in favor of the plaintiff." [14]

From a legal point of view, it's necessary to revise those legislative norms that currently regulate the circulation of digital contributions. A detailed study of all aspects of the currently relevant movement of finance from the sponsor to the author, developer or initiator is required.

4 Conclusions

Necessary and sufficient conditions should be taken into account in indicators for monitoring the process of digitalization of the financial sector and also in the construction of a system for managing structural and digital institutions [15]. An analysis of national and foreign experience has shown that the creation of digital innovations is stimulated by the banking sector and its development trends. In particular, the main trend in the development of the financial sector today is the creation of virtual banks and the Internet banking service.

It should be noted that digitalization processes in many areas of financial services aren't optimal. The legal framework often can't provide a solid foundation for the full functioning of the digitalization of financial services.

In this context, the restructuring of the business model is an excellent opportunity to ensure the effective transformation of not only the business of a single company, but the entire financial industry as a whole, and also to open up completely new areas of growth and sources of income.

Sustainable Development of Economic and Social Systems: Future Prospects for the Digital Economy

Participation of Transnational Companies in the Formation of National Environmental Policy

Olga G. Charykova, Tatyana N. Gogoleva, Salimjon A. Nasriddinov, Alexey V. Shulgin, and Vita I. Kostyleva

Abstract Consideration of the correlation between transnational companies activities and national economic policies. Special features of environmental policies formation of transnational companies were defined. The analysis of the indexes of the rigidity of environmental policy, environmental democracy and environmental performance was performed. The relationship between the level of development of the country and the rigidity of environmental policy was revealed. The environmental activities of the largest Russian companies representing the transport, oil and gas, metallurgical and mining sectors of the economy were analyzed. The tendency of expenses increases for environmental protection, including investment expenses in fixed capital, aimed to protect environment and rational use of natural sources was discovered. Consideration of priority areas of environmental activities for transnational companies. The conclusion about the significant positive impact of TNC activities on the formation of the country's environmental policy was made.

1 Introduction

In the second half of the 20th century, the environmental problem became very urgent due to the rapid development of the market. Companies all around the world annually increase their production, aiming to satisfy the demanding modern consumer, which is followed by a tremendous burden on the environment. Nowadays, humanity has almost overstepped the limit of nature restoration. Future generations that are not consumers at the moment might face the consequences of the irrational use of the natural wealth which current generations are responsible for. Thus, further consumers may become a part suffering damage. The situation when the interests of persons not participating in the transaction, but experiencing the consequences, are not taken into account, economists call "external effects" [1]. The most common example of external effects is environmental pollution. Pollution of soil, water, atmosphere is considered as environmental pollution. The production activity of companies is followed by a negative impact on the environment, and therefore needs environmental regulation. More than half of global industrial production belongs to transnational companies. In modern realities, transnational companies have become the basis for the globalization. The development of transnational companies is explained by the need of production costs reduction in order to gain advantages over competitors. Companies prefer to locate their production in the countries with the cheapest labor and the most lenient legal regulations. Transnational companies are not only the largest producers, but also they make the strongest negative impact on the environment, external effects and consumers of natural resources. To reduce costs and bypass tough environmental requirements, transnational companies relocate production to developing countries which do not have strict environmental legislation.

Thus, TNCs save on investments in environmental protection and harm the ecology of developing countries. However, environmental pollution is a global problem [2]. Developed country emissions will affect neighboring developed countries. It does not matter which country emits CO2, the main thing is that it will aggravate the common for all countries problem of the greenhouse effect [3]. Environmental regulation aimed to reduce the negative external effects of production activities, involves the use of a number of tools. Moreover, priority is given to incentive instruments, such as emissions tax, subsidies for companies engaged in research in the field of "green" technologies, traded emissions permits [4]. Modern consumers have been able To force the market to take into account the external effects of production activities, to internalise them, which demonstrates the decline in demand for non-environmentally friendly products. At present, not only consumer properties of the product are important for the consumer, but also the way this product and materials for it were produced [5]. In this regard, transnational companies began to use the environmental factor as a competitive advantage. In order to create a positive image at the consumer, transnational companies reveal environmentally significant information.

According to the OECD Environmental Policy Severity Index, the countries with the most stringent environmental requirements are Denmark, the Netherlands, Finland, Norway and Switzerland [6]. BRICS countries such as China, India, Indonesia, Brazil, South Africa and Russia have less stringent requirements. Despite the fact that the environmental policy rigidity index has almost doubled over the last decade, China and India have low rankings among all of the countries according to on the Environmental Performance Index. They are on 122 and 170 places respectively. The current situation can be explained by the transition to the best environmental practices which is a long-term process. For developing countries, the weakening of environmental legislation creates a possibility to attract direct foreign investment. Foreign direct investments have a positive impact on the economy of hosting, thus, countries refuse to improve environmental legislation on purpose. The index of ecological democracy illustrates this behaviour of countries. Environmental democracy refers to the right of free access to information on the environment quality, the right to monitor compliance with environmental legislation and the right to compensation for harm, the right to participate in decision-making [7]. The values of the index of ecological democracy (EDI) and the values of the index of ecological efficiency (EPI) are given in the table (table 1) [7, 8].

The average EDI value is 1.42. The average EPI value is 57.4. The data in the table indicates that countries having the most rigid environmental policies, implement principles of ecological democracy, which implies a "transparency" of environmental policies, the publication of environmental performance indicators of companies, the active participation of the society and companies in solving the problem of environmental conservation. Countries that have the lowest rating in list according to the index of environmental democracy, free public access to environmental information is impossible, society cannot participate in solving environmental issues.

Table 1 Country rating by environmental democracy and ecological efficiency indexes

Placeinrating	EDI	Country	EPI	Placeinrating
1	2.39	Lithuania	69.33	29
2	2.31	Latvia	69.12	37
3	2.16	USA	71.19	27
4	2.16	South Africa	44.73	142
8	2.06	Russia	63.79	52
15	1.80	Brazil	60.70	69
17	1.80	Indonesia	46.92	133
20	1.75	India	30.57	177
52	1.10	Bangladesh	29.56	179
55	0.97	Madagascar	33.73	175
59	0.86	Pakistan	37.50	169
70	0.51	Haiti	33.74	174

Such conditions allow companies to save on meeting the requirements of environmental legislation, to reduce the cost of developing or acquiring "clean" technologies. However, it should be borne in mind that such behaviour is practiced by the least developed countries, because these countries have no other opportunities to attract foreign direct investment and improve the economic situation [9].

Bangladesh, Haiti, Cambodia, Madagascar occupy the lowest positions in the presented ratings, and are forced to accept the "dirty" production of transnational companies to maintain their environmental policies.

It should be noted that if TNCs adhere to a single corporate standard that is stricter than the requirements of the national environmental policy, the host country has a positive effect [10].

The environmental policy of transnational companies becomes the "engine" of the national environmental policy. First, the management of transnational companies recognizes that environmental investment has a long payback period, and forms its environmental strategy for 5–10 years, trying to predict the future tightening of environmental legislation requirements. Secondly, transnational companies accept and aim to harmonize various social interests, given the scale of their activities. In a competitive market, they seek to create a positive image among various categories of consumers. The emergence of transnational companies on the national market "provokes" the environmentally responsible behavior of national producers. Finally, transnational companies are ready to contribute to the prevention of possible environmental disasters, the consequences of which will affect their activities.

Table 2 presents the environmental costs of the ten largest Russian companies that are transnational and operate in the oil and gas, metallurgical and mining sectors, as well as in the transport sector of the economy [11–20]. The data presented in the table reflects the environmentally responsible behaviour of transnational companies. Share that companies have spent in 2017 on environmental activities vary from

Table 2 Costs of the largest companies of Russia on environmental protection in 2017

Company	Sector	Environmental costs, billion rubles	The share of expenditure on environmental activities in the total costs of the company, %
Gazprom	Oil and gas	70.82	1.23
Lukoil	Oil and gas	42.41	0.84
Rosneft	Oil and gas	101.7	2.15
Surgutneftegas	Oil and gas	23.9	2.5
Novatek	Oil and gas	2.07	0.5
RZD	Oil and gas	5.0	0.24
Aeroflot	Oil and gas	0.065	0.013
NLMK	Metals and mining	28.8	5.74
NorilskNickel	Metals and mining	26.76	6.56
Severstal	Metals and mining	5.46	1.75

0.013% (Aeroflot) to 6.56% (Norilsk Nickel). Compared to 2016, the expenses of companies increased by 39.3%, which occurred simultaneously with a decrease in payments for the negative impact on the environment in all the companies listed in the table. This indicates a reduction in negative impact. In general, the cost of environmental protection in Russia in 2017 increased compared to 2016. By 11.2% and amounted to 657 billion rubles.

Investments in fixed assets aimed for environmental protection and rational use of natural resources in Russia amounted to 154 billion rubles and exceeded the 2016 level by 6.3%. Investment growth of some of the companies under review exceeded 40%.

It should be noted that each of these ten companies complies with the requirements of the international standard ISO 14001, moreover, it imposes strict requirements on companies cooperating with it. It also provides a reduction of emissions, arranges waste disposal areas to reduce the anthropogenic impact on the environment, and prevents pollution (for example, when transporting goods by sea). Strives for the rational use of natural resources and contributes to the preservation of biodiversity in the regions where it carries out production activities.

The activities of transnational companies have a significant impact on the national environmental policy, contributes to a more rational use of natural resources. Transnational companies are involved in the development of environmentally friendly technologies that cannot be financed exclusively from the state budget, stimulate other market participants to comply with environmental requirements. The strategies of companies serve as a guide for the formation of a national environmental policy.

Selection of Innovative Projects for Technical and Technological Development within Network Management Structure Environment at Industrial Enterprises

Elena Yu. Rebiy, Olga A. Boris, and Elena N. Lepyahova

Abstract Purpose of this chapter is to develop regulations for selection of projects in technical and technological development area, taking in consideration context of network management structure in industrial enterprises. Research methodology is based on evolutionary conception, which implies emergence of new technologies in the process of niche experiments at micro level, followed by selections and consolidation at me so and macro levels; that implies assessment of innovative projects and their implementation results not only for one business unit but also at the same business network. Research and comparison of conditions and implementation methods reveals underlying problems of technological development in business network structure. Those provide for development of optimal set of provisions and models, ensuring most efficient selection of innovative projects. In simple terms, the model includes preliminary selection of projects based on thematic priorities; integrated assessment of selected projects based on innovation criteria; assessment of networking opportunities when selecting and implementing projects; investment appraisal and final project selection. During the study, the authors identified conditions and specific models that determine reliable project evaluation in the context of industrial structures network. Those are applicable when project results are reflected in both: project initiator's performance and its business partners' achievement of goals: Analytic Hierarchy Process, AHP, Rank Inclusion in Criteria Hierarchies (RICH), Robust Portfolio Modelling (RPM). The work includes description of difficulties related to selection process of innovative technological development projects, awareness of which helps to figure out appropriate models for each particular case.

1 Introduction

Timely character of the scrutinized issue on innovative projects selection to ensure technical and technological development is associated with problems of vertical and horizontal coordination between main bodies of industrial enterprise management in the environment of network structure. Technical and technological development represents multi-level management process, which focuses on the issues of sources and components for technological growth, and whether interaction between those leads to generation of significant innovative products.

Growing scientific influence on economic and technological growth, as well as systemic nature of innovative projects, leads to significant importance of coordination and interrelation of various types of knowledge and knowledge generators, both in different disciplines and in various areas of basic and practical research.

Process modelling for project management in technical and technological development area, which includes evaluation and selection of innovative ideas and projects, is based on the theory of systems and applies object-oriented modelling, where selection, explanation and description of complex systems is carried out by means of standard solutions. Hierarchical systems include numerous components (subsystems and elements) that interconnect in one or the other way, so the main task in system modelling is to simplify researched object by means of abstraction.

This adopted modularity simplifies comparison of specific processes results (implemented according to mutually shared methodology) and leads to economies of scale effect (can be repeated and reach lower cost). However, introduction of modular process requires identification of general criterion to ensure comparability of value chains and their interaction, although allows for introduction of new necessary modules.

Purpose of this chapter is to develop conditions, criteria and models for selection of projects in technical and technological development area considering new network management structure in industrial enterprises.

2 Materials and Method

Essence of technical and technological development is described in publications [1–3]. Multi-level management process that focuses at sources and technological growth

components has specific strategic characteristics and issues, as reflected in following works of [4–7].

Specifics of evaluation and selection methods for innovative solutions and technological development projects are defined in works of [8–13].

Specifics of network structure in industrial complex management are reviewed in works of [4, 12, 14–17].

Content analysis of existing scientific literature revealed that approaches proposed by modern scientists to selection of technical and technological development projects do not provide clear understanding of the process in the environment of network management structure at industrial complex enterprises. This makes some comparison models inapplicable and blurs criteria; selection appears as non-essential procedure, which is completely unacceptable and requires model update, the latter determined relevance of this study.

3 Results

Early stages of innovative products selection and mastering reveal essential duties of managerial procedures during implementation of innovation strategies, which are identification and selection of the most attractive innovative ideas and projects to be implemented along with the company's existing project portfolio. Innovative ideas selection practice at this stage is aimed at involving maximum number of stakeholders into joint scientific and technological activities and elaboration of initially different views on future development to more consistent provisions. This stage is carried out with consistent involvement of experts. Systematic character of expertise methods centers around one of expert assessment methods considered as system, and individual stages of expert assessment represent its elements. Since industrial complex structures its internal innovation process in accordance with specific consumers' needs, receipt of adequate and accurate information about new markets sizes, new consumers and their real and unseen needs and preferences become foundational for expert assessment and decision making when choosing projects (ideas).

However, final list of projects should be shortened down and sorted priority-wise; projects' strategic importance for a whole network structure also should be stipulated.

Process of project evaluation and selection is a key element of strategic innovation management in industrial complexes to ensure the latter technological development. Approaches to the issue of priority-wise project selection can be presented generally in four stages:

awareness of need (possibility) for decision making;
articulation of alternative activity options;
evaluation of options according to their attractiveness;
selection of option (s) for implementation.

Selection of projects in accordance to traditional theory of capital investment applies only two of the last stages, as for decision-making- projects evaluation

according to goals and development strategies of an enterprise prevails. Market environment demands consideration of commodity-market projects, and sequence of their evaluation conforms to all four stages.

Selection of innovative projects is quite unique since all alternative variants should be known by the point of decision making, at the same time valid options for new projects may emerge over a given (planned, long-term) period on the ground of innovation practices.

Those may represent innovative proposals formed within industrial complex, new attractive offers in the market environment, and "weak signals" about possible areas of expansion, etc.

Innovative enterprises operate in conditions of uncertainty, it should be considered at the point of criteria system selection for evaluation and selection of innovative projects according to life cycle stages of innovative products. Demand for attractive innovation projects and their evaluation in the context of incomplete information become compulsory. It is also necessary to consider that strategic innovative solutions are usually related to long-term projects.

Selection challenges also arise in determining advantages of one project over another, since decision making includes combination of qualitative and quantitative characteristics, as well as potential cost-sharing effect and unique characteristics of innovation project in case if it is implemented along with existing projects in an enterprise or complex.

Therefore, traditional project selection methodology based on investment evaluation claims for changes and improvements, as well as search for new strategic innovative solutions in uncertainty environment and diversity of choices.

Diversity is primarily necessary for overcoming limitations within developing innovative industrial complex that are associated with previously chosen course of technological development. Traditional restrictions include defined standards, concepts and practices of enterprises, focused mainly on profit growth, which make behavior of individual entities more predictable. They narrow technical and technological capabilities choice variety as well as visions and values, thereby limiting long-term innovative potential.

Most importantly these restrictions regulate selection of innovative ideas at various levels of innovation system: at the levels of individual enterprises, complexes, and further at industrial, regional, and national levels. Therefore, main activities aimed at both strengthening capacity and increasing activity of innovation system are associated with diversity.

Diversity is a critical factor, primarily at early stages of innovation cycle, where direct consideration of various techno-institutional development aspects is crucial, and further during periods of radical technological change, which change components or entire systems, make former competencies irrelevant and promote new values [18].

Therefore, selection of alternative ideas, their prioritization during evaluation and identification of innovative projects require consideration of diversity, which is revealed via range of different possibilities during determination of priorities.

Of course, it seems more appropriate to select alternative ideas while evaluating and selecting projects, giving preference to those that contain promising innovations,

rather than to poor general ideas about the future. I. Ansoff pointed out importance of brief descriptions of vital topics along with associated risks and opportunities [19]. In essence, this represents creation of unique mini-scenarios reflecting alternative vectors of future development, which enhance quality of decisions making.

European practice of innovative project programs preparation suggests readymade universal multi-criteria methods for priority defining, which make it possible to create systems for regular analysis of future opportunities and their use in evaluation processes of potential innovative projects. Main advantage of such tools is creation of a system for regular analysis of future opportunities and its application for evaluation of potential research projects [2, 20–22].

Development of procedural schemes for evaluation and selection of innovative projects when exploiting and implementing innovation strategy requires solving a set of hierarchically interrelated tasks.

Most well-known methods for determining project priorities include: Analytic Hierarchy Process (AHP) [17], Rank Inclusion in Criteria Hierarchies, RICH [12], Robust Portfolio Modeling, (RPM) [23].

Special attention should be given to the method based on robust portfolio modeling including multi-criteria estimation methods. It permits to a greater extent take into account promising viewpoints and innovative ideas, which are put forward both in external and internal environment. In this respect it meets necessary requirements of the present study.

Portfolio modeling includes portfolio analysis (methodology) for generating preliminary lists of project priorities, (ideas) of the required scope, development tendencies, and etc., since trends for innovative technological development ideas should be specified in sound portfolios. Specified priorities are required to ensure efficiency of complex performance in the environment of increasing investments flow into new innovative inventions and shorter product life cycle.

For example, well-known 3 M production corporation (Minnesota Mining and Manufacturing), which operates in innovative markets, accurately tracks composition of products in the corporation's portfolio, which does not exceed 1/3 of new developments in assortment volume of products. Optimal ratio between products with short and long life cycle is also maintained.

Exploitation of multi-criteria evaluation methods for prioritization of scientific and technology projects ensures openness and consistency in creation and implementation of innovation strategy.

Necessary conditions for portfolio selection and evaluation of projects become:

- trends for perspective development of industrial complex;
- industrial complex objectives;
- innovation development strategy trends;
- existing industrial complex performance and existing development projects;
- available bank of back up projects suspended due to lack of resources;
- probability of efficient innovation projects occurrence during budget period;
- degree of probabilistic evaluation of reviewed projects, etc.

Creation of selection criteria system at the stage of identification and selection of ideas is also required.

Product manufacture period criterion is specifically important for innovation activity noted as “rapid transformation” and “at any price” which is accessible for producer with limited resources. Such statement is not always admissible and rational for innovative enterprises; however, in critical situations it can become quite appropriate.

Selection of project portfolios in the environment of limited resources and—occasionally—incomplete information about the relative importance of evaluation criteria and projects functionality according to specified criteria is possible if robust portfolio modeling approach is applied. Robust simulation implies specific innovative ideas as “projects”, and their blocks accordingly form “project portfolios”. Portfolio means a subset of suggested research topics. Therefore, one of the key characteristics of robust portfolio modeling method is possibility to assess attractiveness of certain ideas by analysis at portfolio level.

It is also important to consider practices of inventive projects as semi-structured open networks, which engage increasing number of participants. But since network interactions are not strictly regulated, this experience cannot be applied effectively at selection of criteria for innovative projects and identification of alternative ideas for these projects. But it can be applied for creation of temporary teams seeking for certain associates in optimal ratio for successful completion of specific task; for example, achieving specified technical and technological levels. Due to certain complexity of such projects, they are more suitable for targeted innovation programs than for inventive projects, and require generation of results by means of well-structured interconnections and cooperation networks.

Therewith, analysis of high-tech product development processes, as well as analysis of managing processes over research and development in Russian and foreign companies, showed that increasing complexity of innovative products, along with growing importance of development time shrink disables traditional management processes in the area of innovative developments, where they delay enrolment into the markets and, consequently, increase unexpected costs [10, 11].

Main disadvantages include: low percentage of conceptual management decisions during early stages of innovative products creation life cycle; delayed inclusion of external developers and suppliers at respective stages of innovative products creation life cycle; poor contribution of external sources into research and technology; exclusively local specification for consumer requests, etc.

Networking between developers, manufacturing enterprises, suppliers, higher educational institutions and others takes place in isolation from selection of priority innovative programs and projects. These issues are considered much later, at further stages of innovation project life cycle. Very often the need to consider numerous horizontal and vertical links, both within innovation system and reaching out external environment, increases project implementation period and, consequently, decreases its implementation efficiency.

Identification of possible network connections that (along with development company) are capable to carry out innovative projects from initial design stage was

not sufficiently supported methodologically until recently. Modeling for network collaboration at innovation programs' early stages is complicated with issues related to identification of potential interest among network collaboration participants to be engaged in research and development, and most importantly to evaluation of their capabilities and competencies.

Method of portfolio modelling (robust portfolio modelling) applied for selection of projects allows considering resource related and other constraints during evaluation and selection of innovative projects, and includes network cooperation at early stages of innovative programs.

Application of portfolio modeling method also reveals promising innovative research areas and supports creation of possible interaction arrangements (structures) within network; all of that is aimed at improving efficiency of innovation system via technology transfer upgrade and related to it training processes, it may also contribute to new innovations emerge.

Such interactions in networks are especially relevant to large innovative projects implemented by representatives of scientific institutions and industry, which are invested from different sources and ensure broad involvement. For example, technology platforms and ERA-NET initiatives [7] act as innovation policy instruments to create European Research Area (ERA).

Evaluation of projects as of their assistance to scientific and industrial enterprises is important for project's investment attraction, since such cooperation demonstrates future industry and consumers' demand. It also points at essential interest of scientific organizations, which have status and competencies for successful implementation of innovation project tasks.

So rather than disconnect processes for determining thematic priorities and building cooperative networks in planning and implementation of innovative projects, it is advisable to merge them. That ensures concentration on such ideas that stir up possible generation of new research networks.

Portfolio modeling method was expanded by means of additional criteria that include among other degree of researchers' (organizations') readiness take part in project at the stage of considering and reviewing idea, their level of competence, and etc.

Value of such criteria was estimated by means of optimization algorithm that associates researchers with relevant topics (Fig. 1) and sums up levels of interest expressed by the researchers to this topic.

This way, according to several criteria, portfolio value is understood as weighted total of values related to ideas contained in portfolio, whereas network value represents aggregated level of researchers' interests, which most favourably correlate with ideas in portfolio.

Main provisions of robust portfolio modeling method applied for selection of portfolios remain as the first step in decision making and are further complemented during network modeling.

Considering above listed features of management procedural schemes for evaluation and selection of innovative projects for innovation strategy implementation at industrial enterprises, it is suggested that model system for management procedural

Fig. 1 Network management structure interconnections scheme

schemes for evaluation and selection of projects should be created with inclusion of network management architecture related to the stages of innovative products creation:

– preliminary projects' selection by thematic priorities;
– integrated evaluation of selected projects by innovation criteria;
– assessment of network interactions during projects selection;
– project's investment and risk assessments;
– final selection of innovation project (projects).

Proposed approach to portfolio modeling and project selection for innovation strategy implementation that consider network management architecture at industrial enterprises creates procedure for selection and implementation of technologies for implementing projects for industrial development and efficiency improvement in innovation production systems.

4 Conclusions

So, with reference to increasing dynamism of environmental and network interactions of innovation and investment process participants, difficulties arise in comparison and selection of technological development projects, since this refers to a complicated combination of qualitative and quantitative characteristics as well as effect of merging costs and unique characteristics of a new project with already ongoing implementation of industrial complex projects.

As a result, traditional project selection methodology by means of investment evaluation requires improvement with regards to uncertainty and diversity of choice.

Development of procedure for evaluation and selection of innovative projects also requires solving a set of hierarchically interrelated tasks and selecting project priority areas. Network cooperation at early stages of innovation programs is complicated with difficulties related to identification of potential interest among network collaboration participants to be engaged in research and development, and most importantly to evaluation of their capabilities and competencies.

Robust portfolio modeling method that attracts multi-criteria evaluation methods in conditions of limited resources and incomplete information about relative importance of evaluation criteria significantly increases possibilities to incorporate different viewpoints at selection of promising innovative ideas that are put forward from both external and internal environment of industrial complex. This method allows inclusion of cooperation networks creation during scheduling and implementing innovative researches at early stages of project selection, which merges processes of innovative ideas prioritization and cooperation networks creation during planning and implementing technological development projects.

Current approach suggested in this research refers to portfolio modeling and selection of innovation strategy implementation projects, it takes into account network management structure in industrial enterprises, creates procedure for selection

and application of technologies to manage implementation of innovation strategy and areas for developing capabilities and improving performance of innovation production systems.

Formation of an Effective Strategy of Nature Protection Activities in a Region in the Conditions of the Digital Economy's Development

Alexander A. Fomin, Yuriy A. Tsypkin, Roman A. Kamaev, and Natalya V. Kozlova

Abstract Purpose: The purpose of the paper is to offer scientific and practical recommendations for formation of an effective strategy of nature protection activities in a region in the conditions of the digital economy's development. Design/methodology/approach: Correlation analysis is used for determining the consequences of the digital economy's development for the nature protection activities. The research is performed by the example of top 10 regions of Russia by the level of digitization in 2019. Findings: Cross correlation of the ecological index with digitization, innovations, and "green" investments shows that digitization—as a direction of innovative development of modern regions' economy—could cause ecological risk. A very low return from "green" investments shows that they cannot be a sufficient measure of nature protection activities in regions of modern Russia and require additional supporting measures. Two alternative strategies of nature protection activities in a region from the positions of their effectivenes in the conditions of the digital economy's development are distinguished, and their comparative analysis is performed. Originality/value: It is shown—by the example of top 10 regions of Russia by the level of digitization—that modern regions use the strategy of commercialized digitization, which causes high ecological risks that cannot be overcome even by means of "green" investments. For solving this problem, an alternative, more perspective, strategy of responsible digitization is developed; it allows for high

1 Introduction

In the process of development, modern regions use global initiatives, which are formed under the influence of globalization. 2015 saw the adoption of the global goals of sustainable development, which led to increase of the role of nature protection activities at the regional level. 2015–2018 saw the growth of society and business's attention to the issues of environment protection, which was reflected in publication of ecological reports—especially, among large entrepreneurship.

Then, a new initiative was implemented at the global level—development and dissemination of digital technologies. Under the influence of this initiative, regions began implementing measures in the sphere of modernization and digitization. Transformation of the conditions of regions' competition took place; at first they competed for favorable conditions for human life, and then began competing for the level of business's technology. Though the national and regional programs of digital development were implemented since 2012, they were rather scattered—institutionalization of the practices of building the digital economy in regions started only in 2019.

Having become a new growth vector of the regional economy, digitization formally supplemented the goals of sustainable development—but, as a matter of fact, it ousted them. Publication of ecological reports became a less popular practice, while reports in the sphere of digital development are published more actively. Combination of deregulation and "market gap" in the sphere of environment protection causes a critical level of emergence of an ecological crisis, which prevention is an important scientific and practical problem.

Thus, the purpose of this paper is to offer the scientific and practical recommendations for formation of an effective strategy of nature protection activities in a region in the conditions of the digital economy's development.

2 Materials and Method

Literature overview shows that the set problem has been studied fragmentarily. One block of research comprises the works on nature protection activities based on corporate responsibility, circular economy, and sustainable development: Morozova et al. [1], Inshakov et al. [2], Frolov et al. [3], Popkova et al. [4], Pozdnyakova et al. [5], Popkova et al. [6, 7], Sergi et al. [8, 9], and Zavyalova et al. [10]. Special attention in these works is paid to the specifics of regional economy.

Another block of research comprises the works on the issues of formation and development of the digital economy: Andronova et al. [11], Shulus et al. [12], Ragulina [13], Ragulina et al. [14], Belik et al. [15], Stolyarov et al. [16], Popkova [17], Popkova and Gulzat [18, 19], Popkova and Zmiyak [20], Popkova and Sergi [21, 22], Sergi et al. [8, 9], and Sergi [23].

A systemic vision of the nature protection activities in a region in the conditions of the digital economy's development has not been formed—which is a gap in the existing scientific knowledge. Correlation analysis is used in this paper for determining the consequences of the digital economy's development for the nature protection activities. The research is performed by the example of top 10 regions of Russia by the level of digitization in 2019. The selection of statistical data for the research is shown in Table 1.

3 Results

Based on the data from Table 1, cross correlation is calculated (Fig. 1).

As is shown in Fig. 1, correlation of the ecological index with digitization (8.459%) and environment protection expenditures (6.062%) is low, and with investments in fixed capital is negative (−0.267%). This means that digitization—as a direction of innovative development of modern regions' economy—causes ecological risk. Low return from "green" investments means that they cannot be a sufficient measure of nature protection activities in regions of modern Russia and require additional supporting measures.

Two alternative strategies of nature protection activities in region from the positions of their effectiveness in the conditions of the digital economy's development are distinguished. Their comparative analysis is given in Table 2.

As shown in Table 2, the strategy of commercialized digitization, which is implemented in regions of modern Russia, envisages that the priority of digitization is maximization of commercial profit. The dominating ecological consequences of digitization are growth of energy consumption, depletion of natural resources, and increase of production and consumption waste. Environment protection is to overcome the negative ecological consequences of digitization.

The condition of implementation (investment attractiveness) of the "green" digital technologies is high expected return from investments (potential commercial profit).

Table 1 Statistics of the ecological index, digitization, innovations, and "green" investments in top 10 regions of Russia by the level of digitization in 2019

Top 10 regions of Russia by the level of digitization (in the decreasing order)	Digitization level, points 1–100	Investments in fixed capital per capita, RUB	Environment protection expenditures, % of GRP	Ecological index, points 1–100
Arkhangelsk Oblast (without the autonomous okrug)	100.00	96,483.57	1.51	57
Republic of Tatarstan	68.63	163,668.39	1.28	57
Khanty-Mansi Autonmous Okrug	68.56	653,534.11	1.27	48
Yamalo-Nenets Autonomous Okrug	66.69	1,966,299.23	0.22	56
Moscow Oblast	66.27	312,550.96	0.32	47
Tyumen Oblast	66.09	724,038.17	1.07	61
Republic of Bashkortostan	65.73	34,925.90	1.72	54
Belgorod Oblast	65.16	84,274.23	1.08	68
Tula Oblast	65.02	108,897.91	1.07	48
Lipetsk Oblast	63.22	146,347.56	2.93	54

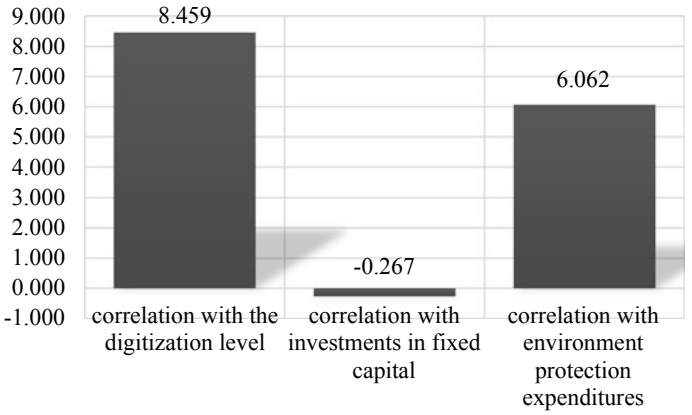

Fig. 1 Cross correlation of the ecological index with digitization, innovations, and "green" investments, % *Source* Calculated and compiled by the authors

Table 2 Comparative analysis of the alternative strategies of nature protection activities in region from the positions of their effectiveness in the conditions of the digital economy's development

Criterion of comparison	Strategy of commercialized digitization	Strategy of responsible digitization
Priority of digitization	Maximization of commercial profit	Creation of public advantages
Dominating ecological consequences of digitization	Growth of energy consumption, depletion of natural resources, increase of production and consumption waste	Creation of "smart" cities, which ensure rational nature use and nature protection activities
Approach to environment protection	For overcoming the negative ecological consequences of digitization	Digitization is a tool of ecological development
Condition of implementation (investment attractiveness) of "green" digital technologies	In case of high expected return from investments (potential commercial profit)	In case of society's large need for them—as a manifestation of corporate responsibility
Market landmark of entrepreneurship's digitization	Increase of profit by means of hi-tech products, despite their ecological consequences	Increase of profit by means of increase of loyalty to ecologically responsible business
Consequences of digitization for "green" investment and innovation initiatives	Digitization becomes the key vector of economy's growth' "green" initiatives go to the background and are implemented by the "leftover principle"	Digitization is combined with "green" investment and innovation initiatives and stimulates their active implementation

Source Developed and compiled by the authors

The market landmark of digitization of entrepreneurship is increase of profit by means of hi-tech products, despite the ecological consequences. The consequences of digitization for "green" investment and innovation initiatives are negative: digitization becomes the key growth vector of economy, and the "green" initiatives go to the background, being implemented by the "leftover principle".

A more preferable alternative is the strategy of responsible digitization, which priority is creation of public advantages. The dominating ecological consequences of digitization include creation of "smart" cities, which ensures rational nature use and nature protection activities. Digitization is a tool of ecological development, and the condition of implementation (investment attractiveness) of the "green" digital technologies is society's high need for them (manifestation of corporate responsibility).

The market landmark of entrepreneurship's digitization is increase of profit by means of increase of loyalty to ecologically responsible business. The consequences of digitization for "green" investment and innovation initiatives are positive: digitization is combined with "green" investment and innovation initiatives and stimulates their implementation. A perspective strategy of nature protection activities in a

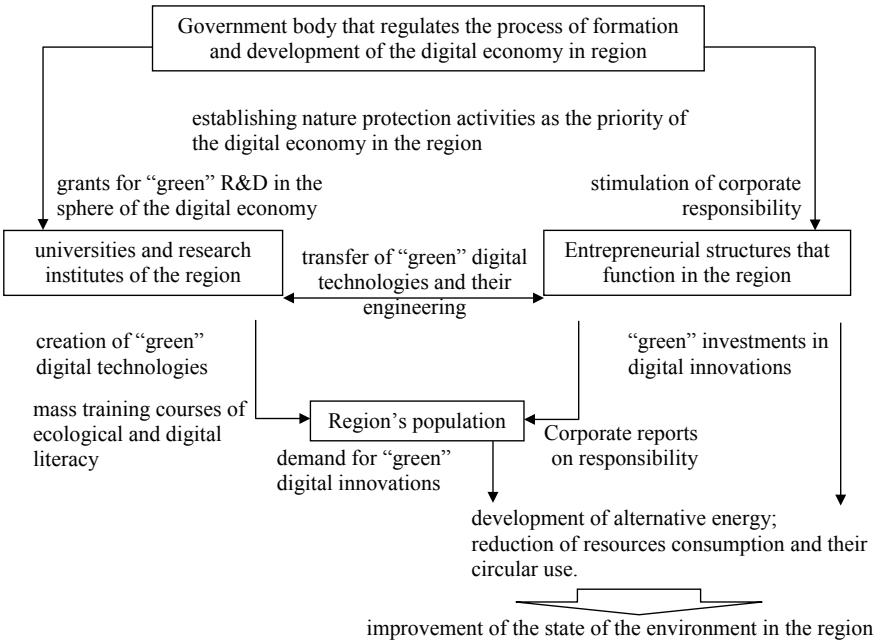

Fig. 2 The perspective strategy of nature protection activities in the region in the conditions of the digital economy's development based on responsible digitization *Source* Developed and compiled by the authors

region in the conditions of the digital economy's development based on responsible digitization is shown in Fig. 2.

As is shown in Fig. 2, in the offered strategy a government body that regulates the process of formation and development of the digital economy in the region conducts active regulation (refusal from deregulation is achieved), which is implemented in two directions simultaneously: sustainable development and digitization. This body establishes nature protection activities as the priority of the digital economy in the region. It provides universities and research institutes of the region with grants for "green" R&D in the sphere of the digital economy and stimulates corporate responsibility of entrepreneurial structures that function in the region.

Mass training courses of ecological and digital literacy stimulate demand for "green" digital innovations, which stimulates "green" investments in digital innovations and publication of corporate reports on responsibility. Thus, responsible production and consumption allow achieving the development of alternative energy, reduction of consumption of resources, and their circular (wasteless) use. All this leads to improvement of the state of the region's environment.

4 Conclusion

Thus, it has been shown—by the example of top 10 regions of Russia by the level of digitization—that modern regions use the strategy of commercialized digitization, which could lead to high ecological risks, which cannot be overcome even by means of "green" investments. For solving this problem, an alternative—more perspective—strategy of responsible digitization is offered—it allows for effective digitization and sustainable development of the region. The scientific and practical recommendations for implementing this strategy are offered. It has been proved that formation of an effective strategy of nature protection activities in a region in the conditions of the digital economy's development should be based on the concept of "green" digitization. It should be studied and elaborated in further studies.

The Concept Interpretation of Sustainable Development Mechanism in the Conditions of Technological Transformation of Industrial Enterprises

Elena P. Kozlova, Svetlana N. Kuznetsova, Ekaterina P. Garina, Elena V. Romanovskaya, and Natalia S. Andryashina

Abstract Modern production in a globalized economy requires a change in approaches in terms of increasing competitiveness, which directly depends on the ability of enterprises to adapt to constant changes in the external and internal environment. A solution to this problem is possible when forming an effective mechanism for sustainable development based on technological transformation, which is especially relevant for the current stage of development of the Russian economy. The purpose of this study is to analyze the basic concepts included in the category "mechanism of sustainable development of an industrial enterprise", as well as improve this terminology based on a matrix approach. The methodology includes theoretical and cognitive (formalization, ascent from the abstract to the concrete) and general logical (analysis and synthesis) methods. As a result of the study on the basis of the works of domestic authors, the concepts of "mechanism", "development", "sustainability" were allocated, which formed the basis necessary for formation of categorical matrix. The most accurate and specific wording of the "mechanism for the sustainable development of industrial enterprises" is formulated. This is typical for industrial organizations in the conditions of technological transformation and contributes to the rational adoption of managerial decisions. The need for a new approach to clarify the essence and content of the concept of "mechanism of sustainable development of industrial enterprises" is due to the lack of a holistic approach in this category. We should also find a simple and understandable practical way to

analyze the state and formation of the mechanism of sustainable development, which suggests the dedication of this study selection of solutions to the above problems. Based on the foregoing, taking into account the specifics of industrial enterprises and using mathematical methods of modeling, a categorical matrix of the concept "mechanism of sustainable development of industrial enterprises" is compiled in our article.

Keywords Sustainable development · Categorical matrix · Methods of mathematical modeling · Mechanism · Industrial enterprise

1 Introduction

Analysis of modern tendencies of development of the human community, it can be noted its large-scale transformation under the influence of scientific, technical and social progress, which covered almost all spheres of human activity. New trends have significantly strengthened the role of technological change in the process of socio-economic development. These positions are based on strengthening the possible impact of scientific and technological achievements on various areas of society. In accordance with this there is a change in the set of basic factors and sources of economic growth [1] .

Sustainable development is one of the priority areas contributing to the growth of competitiveness. The audit company PwC examined the corporate reporting of 729 companies from 21 countries for 2018. The study involved companies from 6 industries: 25%—companies that manufacture industrial goods; 19% - companies that provide financial services; 17% —enterprises that work in the field of media, telecommunications and technology; 17%—retailers and companies that produce consumer goods; 8% are transport and logistics companies. In Russia, 41 companies took part in the study.

The study showed that most companies are still not completely confident in the methods of integrating sustainable development into their strategy. And 72% of companies surveyed in the world and 43% in Russia mention goals in their reports. Only half of the participating research organizations identified priority areas for sustainable development, only 27% included mention of it in their strategy [2].

The reason for not being ready to integrate sustainable development goals is the lack of culture and tools for their implementation. Existing mechanisms are quite extensive for their implementation within one company. In these conditions, to ensure the sustainable development of the enterprise, there is a need to develop such a mechanism that will take into account characteristics of a particular enterprise, as well as their technological transformations. All this makes the problems of disclosing the content of the mechanism of sustainable development more relevant, which allows for more efficient organization of production activities.

In the works of scientists related to the formation of the mechanism of sustainable development, various interpretations of this concept are proposed:

– "This is the ability of organizations operating in the industry to successfully compete in the internal and external markets on the basis of favorable environmental conditions, developing in the system of intercompany cooperation, and the presence of effective market institutions within the industry" [3];

"This is a specific system: targeted management system; a system of forms, methods, norms, rules that control the state of the organization; organizational system, which is a set of units; a system based on organizational and economic relations" [4];

"This is a complex of elements of the production process, ways of organizing the relationships between elements, forms of organization, methods, tools that help a company to sustainably develop activities in the economic sphere using innovative procedures" [5].

Despite the presence in the scientific literature of many interpretations of "sustainable development mechanism", all of them are not fully adapted to industrial enterprises that are experiencing the impact of technological transformation processes as part of their business activities. This necessitates the disclosure of this economic concept in accordance with the existing prospects and features of development of industrial production in the modern economy. At present, there is no terminology focused on the industry. Contribution of technological transformations to the process of establishing the enterprise on the path of sustainable development is poorly taken into account. Under the conditions of this trend, technology is being modified into the main resource of society, gaining new economic content, as well as the transformation of technological methods of production and technological structures. This process can conditionally be called technological transformation.

In this regard, it is necessary to clarify and supplement the terminology that will determine the mechanism of sustainable development of an industrial enterprise in terms of transformations in the field of science and technology. The ability of enterprises to renew production together with scientific and technological development will have a significant impact on the effective development and investment attractiveness of the industry as a whole.

When studying the problem of forming the management mechanism of industrial enterprises, it is necessary to clarify in the economic meaning such a category as "mechanism of sustainable development of industrial enterprises".

The need for a new approach to clarify the essence and the concept of "mechanism of sustainable development of industrial enterprises" is due to the lack of a holistic approach to this category. We should also find a simple and understandable way to analyze the state and the formation of the mechanism of sustainable development. It is tempting to think of initiation of this study for solution of above problems [6].

2 Methodology

Based on the foregoing, taking into account the specifics of industrial enterprises and using mathematical methods of modeling, a categorical matrix of the concept of "sustainable development mechanism" is put together in the article.

The matrix is an object of mathematical research written in the form of a rectangular table of numbers (in our case, instead of numbers, we will insert concepts related to a particular category of words). We will compose a square matrix of the category "Sustainable Development Mechanism" (SDM) [7].

The study examined the following categories: "Mechanism", "sustainability", and "development". We single out the basic components of the concept included in the category of "sustainable development mechanism" and present them in the form of Table 1.

Based on the above definitions, we compose a matrix of SDM, in which each row will correspond to one of the concepts "mechanism", "stability", "development", and from this definition we will choose three main categories:

$$\mathrm{SDM} = \begin{pmatrix} \text{set of system elements} & \text{functioning} & \text{definite result} \\ \text{system ability} & \text{state of equilibrium} & \text{influence of factors} \\ \text{irreversible changes} & \text{influence of factors} & \text{quantitative and qualitative transformations} \end{pmatrix}$$

In order to set the direction of a vector in this matrix, we multiply it by the category "industrial enterprise", which will be a vector $\vec{\Pi}$ that sets the direction to the whole definition.

Table 1 The conceptual apparatus of the sustainable development mechanism

No.	Category	Definition	Basic components
1	Mechanism	A complex of interconnected elements of the system, which is allowing to ensure its vital activity and leading to a specific result [8]	– Set of system elements – Functioning – Specific result
2	Sustainability	Ability of the system to return to an equilibrium state, which has the most favorable effect for the system to perform its functions after the influence of various external factors [9]	– System ability – State of equilibrium – Influence of factors
3	Development	Irreversible process directed and logical changes occurring under the influence of factors leading to quantitative and qualitative transformations [10]	– Irreversible changes – Influence of factors – Quantitative and qualitative transformations

Since the vector $\overrightarrow{\Pi}$ sets the direction of the entire category, it is necessary to identify the specific features of modern industrial enterprises that are experiencing, as part of their business, with the impact of technological transformation processes. It is worth noting that any industrial enterprise, depending on the industry, type and size, also has a number of its own specific features, but in this study we considered only general ones. These include:

– Close relationship with the external and internal environment. Industrial enterprises can adapt within certain limits to both internal and external influences, although the rate of change depends on the complexity of a produced product. This feature should be taken into account in the sustainable development of the organization. It is necessary to determine possible external and internal factors affecting the enterprise, and to develop a number of measures to maintain stability in all kinds of conditions, including technological modification processes [11].
– The unity of production and technological processes. It manifests itself in the common goal and the union of all structural units related to it during implementation of the production program. A high variety of production processes and management taking place at the enterprise entail the formulation of a whole complex of tasks. Sustainable development of the enterprise as a whole will depend on the successful work of each unit, because it is a single system [12].
– Economic independence. An industrial enterprise carries out its activities on the basis of an annual program. At same time observing the regime of economics and economic accounting, while being positioned as an independent economic unit. Current trends must be taken into account and implemented;

1. Implementation as part of its change of technological means. In the Russian Federation, a series of programs has been developed regarding technological modernization, including the draft state program "Scientific and technological development of the Russian Federation for 2018–2025", as well as the "Program for the development of the digital economy until 2035" [13], which reflects technological trends in the digital transformation of industry, some of which can now be applied by industrial enterprises;

– Presence of highly qualified personnel. A very important feature of any modern industrial enterprise is the personnel and their qualifications, as well as the ability of employees to adapt to transformations in the technological process. Only an experienced and qualified employee can create a quality and competitive product. Only with a truly high-quality product we can talk about further sustainable development [14].

Depending on the industry, type and size of any industrial enterprise also has a number of its own specific features, but in this study, we considered only general ones.

By an industrial enterprise we mean an organization that creates industrial products and which is usually a specific object: plant, factory, mine, quarry, plant, etc. [6].

3 Results

Based on the definition of an industrial enterprise and the identified features, we offer the following type of vector $\overrightarrow{\Pi}$:

$$\overrightarrow{\Pi} = \left(\text{organization industrial products feature}\right)$$

Multiplication of a matrix by a vector is performed according to the rule "row by column. To get the next element with coordinates (M is the row number, N is the column number) of the result matrix. It is necessary to add results of the M row elements of the first matrix by the elements of the N column in the second matrix. In literal terms, it looks like this:

$$SDM \times \overrightarrow{\Pi} = \begin{pmatrix} a_{11}\ a_{12}\ a_{13} \\ a_{21}\ a_{22}\ a_{23} \\ a_{31}\ a_{32}\ a_{33} \end{pmatrix} \times \begin{pmatrix} b_1 \\ b_2 \\ b_3 \end{pmatrix}$$

$a_{11}, a_{12}, a_{13}, a_{21}, a_{22} u\, m.\partial.$—these are the concepts corresponding to one or another category of words: "Mechanism", "sustainability", "development".

b_1, b_2, b_3—these are concepts corresponding to the category "industrial enterprise"

$$\text{SDM} \times \overrightarrow{\Pi} = \begin{pmatrix} a_{11}\ a_{12}\ a_{13} \\ a_{21}\ a_{22}\ a_{23} \\ a_{31}\ a_{32}\ a_{33} \end{pmatrix} \times \begin{pmatrix} b_1 \\ b_2 \\ b_3 \end{pmatrix} = \begin{pmatrix} a_{11} \cdot b_1 + a_{12\cdot} \cdot b_2 + a_{13} \cdot b_3 \\ a_{21} \cdot b_1 + a_{22} \cdot b_2 + a_{23} \cdot b_3 \cdot \\ a_{31} \cdot b_1 \quad + a_{32} \cdot b_2\ a_{33} \cdot b_3 \end{pmatrix}$$

$$= \begin{pmatrix} c_1 \\ c_2 \\ c_3 \end{pmatrix}$$

c_1, c_2, c_3—these are the components of a new definition of the category "mechanism of sustainable development of an industrial enterprise.

Thus, using this algorithm, and multiplying SDM matrix and a vector $\overrightarrow{\Pi}$, we obtain the following expression:

$SDM \times \overrightarrow{\Pi}$ = (a set of elements of the organization + the possibility of promoting + irreversible changes in the facility;

functioning of the organization + achievement of equilibrium + impact of factors on the object;

a definite result in development of the organization + influence of factors on the result of creating products + quantitative and qualitative transformations of the object.)

4 Conclusion

A different approach to clarifying the essence and content of the concept of "the mechanism of sustainable development of industrial enterprises", based on the use of mathematical modeling methods. Allowed us to define this category as a set of elements of the organization system that contribute to the functioning, promotion and development of the enterprise using a change of technological means of production, leading to formation of quantitative, and qualitative transformations in order to achieve a state of equilibrium and pre-identified results.

An improved definition will help in the further search for a simple and affordable practical way of analyzing the state and improving the mechanism of sustainable development in the conditions of technological transformation. Moreover, a more accurate and concrete definition of the "mechanism for the sustainable development of industrial enterprises" characteristic of industrial enterprises contributes to the rational adoption of managerial decisions.

Digitalization of the Economy as a Factor of Sustainable Development in the Regions of Russia and Belarus

Larisa V. Narkevich, Alexey F. Rogachev, and Pavel V. Terelianskiy

Abstract The purpose of the study is to justify the prerequisites and priority lines for the transformation of regional cooperation between countries in the context of global digitalization. The objective of the study is to assess the foreign economic potential in the system of integration cooperation between the regions of Russia and Belarus, on which the contribution of the digital technologies to be introduced in small and medium-sized enterprises (SMEs) to the macroeconomic parameters of the national economy, including the scope and nature of diffusion of SMEs foreign economic activity, is contingent. Economic and statistical studies were conducted in the composed information-analytical environment, mainly using the example of the Mogilev region. Studies have found out that the introduction of digital technologies in business processes is a driver of the performance of SME's foreign economic activity amidst the regional integration of the Russian Federation (RF) and the Republic of Belarus (RB). It has been established that both information communication tools under use (electronic document flow management, application of e-commerce platforms to gain access to international markets), and the very concept of arranging a foreign economic activity need changes. The study revealed a low involvement of the region in the foreign trade turnover of the republic; inertia and geographical imbalances in the foreign economic turnover and its commodity composition; underutilization of potentials of cross-border cooperation, including SME, organizations of free economic zone "Mogilev" (enterprises of machine engineering, construction, wood-processing, highway transport industries). The foreign economic activity of SME in the Mogilev region is distinguished by a prudent approach to the product range structure of export and import turnover with a high share of intermediate and

1 Introduction

One of the priority areas of the digital economy is the composition of an information-analytical environment for the management of the foreign economic activity of countries. A coordinated digital policy of the Republic of Belarus and the Russian Federation will help to avoid the emergence of digital barriers in the relations between SMEs of different countries [1]. The current importance of digitalization in the segment of interregional cooperation between economies hinges on cross-country barriers to be overcome and the conditions for small businesses and consumer welfare to be improved [2].

Digitalization in inter-regional cooperation of countries reduces transaction and supply costs; facilitates the solution of multivariate problems of choosing a supplier and consumer; improves the range of export-import operations; establish conditions for high-speed document flow management and paperless trade with an account of optimized stocks of raw materials and finished products, which ultimately contributes to the attainment of the recommended proportions, receivables and payables, positive and negative cash flows [3]. The urgency of creating a digital environment for regional economic relations is explained by the need to implement strategies on the support of sustainable regional development, leaping globalization processes, as well as sanctions in the global economy [4].

The system of digital integration at the state level, including the Russian Federation and the Republic of Belarus, has created new opportunities and premises for the development of international trade cooperation [5].

2 Methodology

Statistical data during the research was taken from the Federal State Statistics Services of the Russian Federation and the Republic of Belarus. The legal and statutory regulation of procedures for the development of the digital environment is stipulated within the National List of Indicators, the Sustainable Development Strategy of the Mogilev Region and the High-Tech Park Development Strategy (HTP), approved

by the Decree No. 8 of President of the Republic of Belarus "On the Development of the Digital Economy" on December 21, 2017 [6]. Regional nuances of economic activities were evaluated through statistical and economic-mathematical simulation.

3 Findings

The potential of inter-regional cooperation of the Mogilev region within integration between Russia and Belarus has some features identified in the study of the foreign economic potential of the Mogilev region in the system of inter-regional cooperation of Russia and Belarus: negative trend and a low share of the Mogilev region in the macroeconomic indicators of the international trade turnover of the Republic of Belarus; growing proportion of export turnover relative to GRP under a value close to the level of Belarus; the concentration of exports of the Mogilev region across 5 regions of the Russian Federation in 2018 made up 87.53%, which matches a high level of market risks; ambiguous assessment of the level of economic ties between the regions of Russian-Belarusian integration (in particular, the largest volumes of foreign trade turnover of the Mogilev region accrue to Moscow, Central, Volga and North-West federal districts; a high percentage of SMEs in macroeconomic indicators of foreign trade activity of the region under research; commodity pattern of foreign trade turnover of the Mogilev region is prevailed by intermediate food products, at the same time a low share of investment high-tech products; lagging development of foreign trade at the border of Russia and Belarus; underutilization by SMEs of the infrastructural capabilities of digitalization provided by free economic zones the Mogilev region; unavailable large-scale SME development projects at the territories near the border of Russia and Belarus [5].

A high-potential platform for the introduction of digital technologies is the foreign economic activity of small and medium-sized enterprises [7]. SMEs make a sizeable contribution to the growth of macroeconomic parameters of foreign trade cooperation between Belarus and the Russian Federation in the system of sustainable development indicators of the national economy and regions. The export of goods by SMEs in the republic amounted to $ 17.1 billion as of 2018, which is 24.8% higher against 2017; in the Mogilev region, the above parameter is estimated at $ 0.678 billion (a 3.96% share in the regional export) and 10.6% increase (Fig. 1). The import of goods by SMEs across the republic did not change and showed a slightly positive balance of foreign economic turnover at $ 19 million; in terms of the Mogilev region: $ 0.566 billion (share in the import pattern 3.31%); the positive balance of $ 0.112 billion.

A positive trend was discovered in the volumes of export and import of goods by SMEs. The average annual growth rate made up 105.9 and 103.5% respectively, which corresponds to a positive foreign trade balance.

Structural imbalances in the growth of foreign economic development parameters of the Mogilev region by SMEs incorporation forms have been highlighted (Fig. 2). The proportion of medium-sized enterprises in the foreign trade turnover of the Mogilev region is found at 14.6%, micro and small enterprises—at 21.9%.

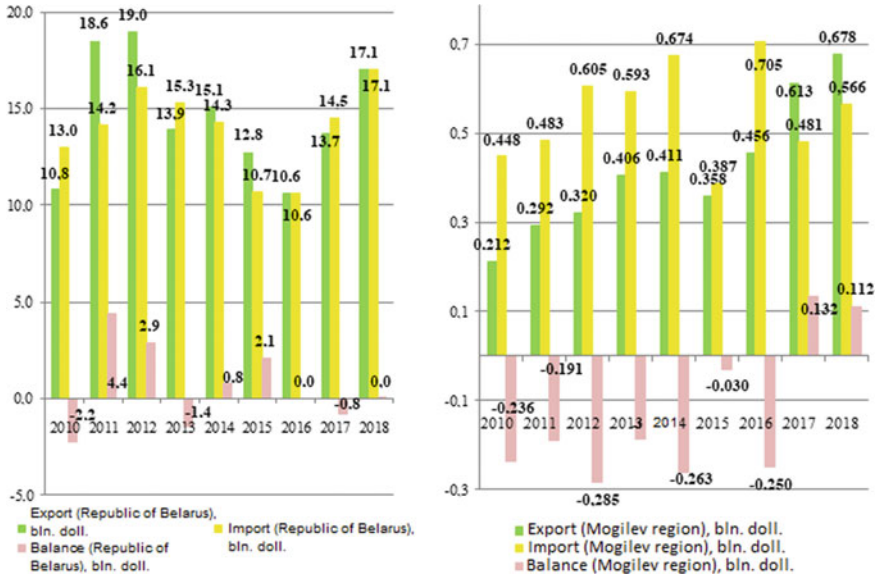

Fig. 1 The volume of foreign trade in goods of micro, small and medium-sized enterprises, billion dollars. *Source* [17]

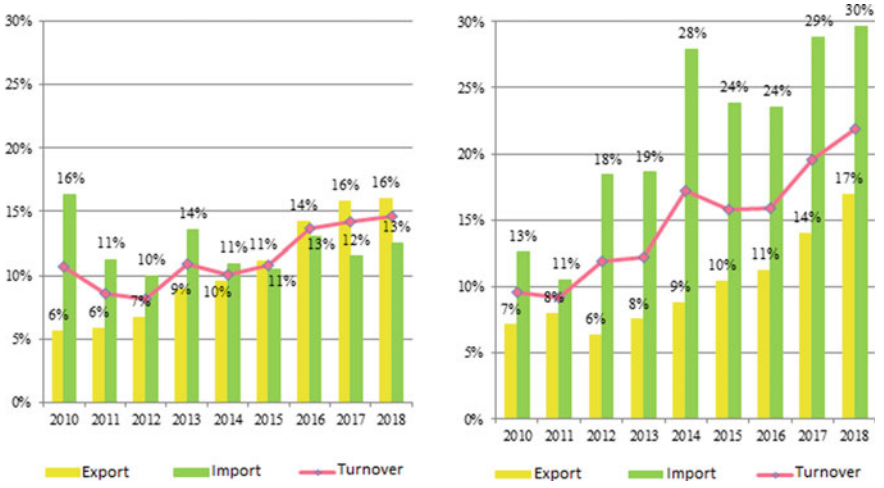

a) the share of medium-sized enterprises

b) the share of micro and small-sizedenterprises

Fig. 2 The dynamic pattern of SMEs' share in the foreign trade of the Mogilev region over 2010–2018, percent. *Source* [8]

The exports of medium-sized enterprises demonstrate a positive trend (basic increase in the share of 10.4 p.p.; chain increase—0.2 p.p.), micro and small enterprises (basic increase in the share of 9.8 p.p.; chain—2.9 p.p.).

As for medium-sized enterprises, imports overrun exports and shaped a negative balance up to 2015; the subsequent core indicator marked a positive balance of export-import operations in this segment of SMEs. The outstripping growth of micro and small enterprises in the turnover of imports of goods in relation to the export trend provided a negative balance of foreign trade in this sector of SMEs. In 2018, the import-export pattern of the Mogilev region was mainly represented by the chemical industry, agricultural raw materials, and processed products, as well as industrial equipment.

Foreign trade turnover of micro, small and medium-sized enterprises of the Mogilev region was mentioned in many segments of the regional cooperation of the Russian Federation. SMEs of the region were marked by large amounts of foreign trade turnover in many regions of Russia. For instance, in 2018, the Mogilev region supported trade relations with 77 Russian regions, in 47 of them export deliveries increased [5]. In 2018 within the concluded Agreements the region aggressively cooperated both with the neighboring regions like Smolensk (export growth rate of 121.8%) and Bryansk regions (114.9%), as well as Moscow (93.1%), St. Petersburg (136.4%), Moscow (111.2%), Leningrad (86.1%), Rostov regions (104.5%) [8]. The findings of statistical analysis showed a significant proportion of the foreign trade turnover of SMEs with the republics of Tatarstan and Bashkortostan, the Nizhny Novgorod and Samara regions [5].

At the district level, the largest volumes of foreign trade accrue to Mogilev and Bobruisk; Mogilev district; Kostyukovichskiy district; Goretskiy district; Osipovichskiy district; Kirovskiy district, Bobruisk district [8].

The product range structure of SME's foreign trade turnover with the Russian Federation is relatively stable. The products of chemical industries, machine and instrument engineering, metallurgical industry, as well as the light and food industries (including dairy, meat, and processed meat products), construction and woodworking industries. Vertical analysis of the commodity pattern of the foreign trade turnover of the Mogilev region and Russia exhibits the low turnover of investment goods and high-tech products [5].

In the field of the digital economy, the regions cooperate within the following directions [9].

Information penetration in local government and self-government bodies of the Mogilev region of Belarus within e-government services. The information space of local government and self-government bodies of the above region is shaped as a corporate information network of local government and self-government bodies with 70 local computing networks of all regional executive authorities and 179 local Councils of Deputies, including 155 rural Councils of Deputies, connected.

At the regional level, information communication is provided by five licensed regional information services operating based on a server cluster located in the switching center: corporate mail; regional Intranet portal; a regional system of

unified communications; a departmental system of electronic document management; regional server of the automated information system "Local Councils of Deputies".

The regional Intranet portal created 114 nodes of regional executive committee divisions and other collective workgroups for 900 users with information collection systems at the executive level of the Mogilev region of the Republic of Belarus, the city of Mogilev, and the Mogilev district automatically generating summary reports.

The departmental system of electronic document management "Electronic Business" implemented with one access point in the switching center of the corporate network has 836 client places. Under Decree of the President of the Republic of Belarus No. 157 on April 4, 2010, the document management system is integrated with the same interdepartmental system of state bodies.

The site of the Mogilev regional executive committee of the Republic of Belarus is the largest and most often used information resource of the region (over 90 thousand unique visitors, over 290 thousand views per month).

In addition to keeping the main information sections of the site attached to the structural divisions of the regional executive committee up-to-date, the portal annually publishes over 200 news pieces (more than 70% of them are copyright) and 120 author's photos (on the life of Mogilev and the region) and weekly presents videonews. Most news articles are used by local newspapers, radio, and television for making up their newscasts. The site is closely integrated with social networks (own youtube and twitter channel), which allows sharing news and photos with others in a couple of clicks.

In 2018, electronic administrative procedures in relation to SMEs reached 75% of the total number; blocks of open data of state bodies and organizations accounted for 100 units.

Digitalization of SME business processes in the foreign trade: the feature set of Web site "Unified State Register" (http://egr.gov.by) has been expanded with some electronic procedures (for example, a notification on a change of location, manager (another person) authorized to act on behalf of the organization); checking the data contained in the USR on the business entity of interest; drawing up an application for submission in person or by mail.

SMEs are enabled to send documents for liquidation (termination of activity) through the USR web site.

Implementation of projects by HTP residents in the Mogilev region, expansion of the activities of IT companies and Mogilev Regional Development Agency OAO. The Agency is accomplishing a project on the establishment of IT parks, teaching language programming, and integrating IT student and scientific developments in the SME economy (more than 10 projects for 2018).

Historically, most organizations have applied IT to reduce costs through the conversion of paper-based processes to cheaper digital ones [10]. SMEs are developing thanks to information transformation, which provides a high awareness and prompt trade and intermediary operations and in turn, dramatically reduces the

production and transaction costs of inter-regional trade. But now SME organizations are keen on finding new sources of income by using digital processes, such as technology parks.

A promising line in the development of regional foreign economic activity is the design of a unified digital platform for inter-regional cooperation based on SME digitalization space services [11]. The digital platform will allow for direct communication between partners within joint SMEs. Therewith, common standards, infrastructure management, and development of digital transport corridors are deemed as the prerequisites for integration of digital infrastructure in the regions of Russia and Belarus [12].

In this block of digitalization of the SMEs economy in the Mogilev region of Belarus, the establishment of some joint ventures (productions) are recognized the high-profile projects:

– enterprises manufacturing professional sports equipment in the free economic zone "Mogilev" (Foreign Production Unitary Enterprise "FORMAN Products");
– enterprises producing biofuels and organic compounds in the free economic zone "Mogilev";
– upgrade of the existing production of pre-insulated pipes and fittings and arrangement of new productions in the free economic zone "Mogilev" (Polymer Pipe Plant ZAO).

Besides, there are two ongoing investment projects with the participation of Russian capital in Mogilev region in the framework of the concluded investment agreements with the Republic of Belarus:

– UNIMILK Invest SOO ("set of organizational and technical measures aimed at the development of the milk processing industry…" in the city of Shklov of Mogilev region;
– Omsk Carbon Mogilev IOOO (launch of production of carbon black in the free economic zone "Mogilev" (the founder is group company Omsktekhuglerod OOO).

In the system of SME's foreign economic activity, digitalization ensures the execution of customs processes and speeds up the movement of goods and services, which reduces their cost. Relevant projects on paperless trade and traceability of goods.

Coordinating digitalization is a key factor for enhancement of the competitiveness of the regions in Russia and Belarus from the perspective of opportunities for inter-regional cooperation within EAEU acting as a large-scale platform for digitalization of SMEs foreign trade operations to take advantage of the integration [13].

The EAEU assumes the digital transformation of SME business processes on the back of Eurasian technology platforms to bolster the competitiveness of small and medium-sized businesses and efficient use of regional economic potential. Prospects for joint innovation and investment projects lay down a single platform for the growth of the regional scientific and technical potential of the countries. The entrenchment of digitalization tools in the mechanisms of SME's inter-regional cooperation patterns will ensure the sustainable development of the regions to a large extent [14].

The applications of digital economy tools are the development of SMEs integration in the service sector, improvement of the business climate, and elevation of investment attractiveness (Malinetskiy 2017). In 2018, 43 service sectors were included in a single market. The services of digitalization institutions are available to all regional SMEs of the Russian Federation and the Republic of Belarus on the terms of the trust to the staff's expertise.

Economic digitalization is aimed at four principles such as facilitation, acceleration, convenience, cheapening of business processes. There are negative points in the organization of SME digitalization. For example, legislative coercion into a contract with a sole service provider (see Article 2 and Article 391 of the Civil Code of the Republic of Belarus), unreasonably high price of these services, and their low quality. The cost of electronic document management services "WEB SMDO" is more than 10 (or even 21) times higher than the cost of alternative methods of communication delivery: (connection to WEB SDMO is 684.3 rubles; maintenance is 99 rubles per month; + communication channel is 12.5 rubles monthly).

The number of e-mails is up to 300 per year (25 per month, including incoming and outgoing). With that, resending an e-mail via an ordinary mail service (for example, Google) using the Internet is free. SMDO propounded by National Center for Electronic Services is inconvenient, non-alternative, cost-inefficient, and compulsory.

4 Conclusions

Small and medium-sized enterprises are important structural elements shaping the foreign economic potential of Russia and Belarus, countries' regions, which foregrounds the introduction of tools for economic digitalization tools in this sector and field of activity. The footing of SME's foreign economic activity is the inter-regional cooperation of the Mogilev region with the partner regions of the Russian Federation. The positive growth rates of the foreign economic turnover of micro, small and medium-sized enterprises and their higher share in the foreign trade turnover of the Mogilev region with a commitment to a positive balance are considered as prerequisites for transfer of business processes into digital space.

The profile of macroeconomic parameters has changed. The average annual growth rate of foreign trade in SMEs across the Republic of Belarus and the Mogilev region amounted to 5.89 and 3.45% respectively under a positive balance. The export potential of both medium-sized enterprises (16% share in the volume of exports for 2018, which exceeds the 2010 figures by 10 p.p., as well as micro and small ones (17% share, 10 p.p. basic increase in the share) is noticeable. Micro and small enterprises are highly active in the import of the Republic of Belarus. In 2018, their share reached 30% (accretion in the share over 2010–2018 is 17 p.p.).

The foreign economic activity of SME in the Mogilev region is distinguished by a prudent approach to the product range structure of export and import turnover with

a high share of intermediate and food products and a low proportion of investment and high-tech goods.

All the negative points constraining foreign economic activity in the system of sustainable development of the regions can be largely overcome by a single digital platform for regional cooperation of the Russian Federation and the Republic of Belarus [15].

The following lines for the transformation of regional cooperation between countries in the context of global digitalization are prioritized:

- development of the information space of local government and self-government bodies of the Mogilev region;
- facilitation of document management and regional commodity turnover due to common standards, infrastructure administration, the establishment of digital transport corridors;
- the employment of digital and ICT technologies relying on HTP in the Mogilev region to increase the performance of SMEs foreign economic activity;
- simplification of customs procedures within electronic (digital) customs;
- development of infrastructure for digitalization of SMEs interregional activities [16];
- more efficient engagement of SME's foreign economic potential in neighboring regions on the back of free economic zone digitalization.

Trends in the Formation of the Digital Educational Environment of Universities

Nataliya V. Kokoreva, Marina V. Orlova, and Svetlana A. Silina

Abstract The rapidly expanding digital economy requires a quick response of the education system to the changing demands of citizens, society, the state, and business. In this regard, there is a need to create a digital educational environment of the university, as one of the main areas that ensure its competitiveness in modern realities. The aim of the study is to identify the main directions of the formation of a competitive digital educational environment of the university. In this regard, a review of legislative documents was carried out, an analysis of scientific publications in the context of the digital transformation of education, an analysis of the results of our own research, which, together, was the methodological basis of this work. The creation of a digital educational environment is considered in the article from the perspective of a marketing approach, carried out with a focus on the market- its trends, opportunities and strategic development prospects; to the requests of various target groups, considering the joint creation of value in achieving the goals of self-development and self-education of students. In solving the tasks, the authors investigated the trends of modern education in the context of the digital economy; identified the problems that need to be addressed to remove obstacles to the effective use of the digital educational environment of the university; priority tasks are formulated that need to be addressed. The novelty of the study lies in determining the directions for the formation of a competitive digital educational environment based on a systematic integrated approach to solving priority problems in the process of its transformation. The results can be used both by higher educational institutions and other educational institutions.

1 Introduction

The modern world is characterized by the rapid development of digital technology. Robotization, information visualization, artificial intelligence, cloud computing, digital services, virtual reality technologies, blockchain and other innovations bring changes to all areas of socio-economic activity, open a window for opportunities and focus on fundamental changes in the world of skills, qualifications, and professions.

Given the high pace of work of any skilled worker, the increasing complexity of production and business processes, the labor market puts forward new requirements for professional qualities, for mastering new types of activities and, first of all, for competencies: universal, so-called soft, hard and digital skills.

Russia, which has an intellectual and scientific base, has enormous potential to accelerate the pace of digitalization, the purpose of which is to improve the quality of life of citizens, economic growth, competitiveness and national security of the country.

The system of higher education is called upon to ensure a confident transition to the digital age for society. The restructuring of the educational infrastructure to new requirements is necessary, because today, the competitiveness of organizations, including universities, is determined by their digitalization level. This requires, first of all, human, financial resources, competent management decisions. The primary task is the creation and development of a competitive digital educational environment of the university.

2 Background and Methodology

An analysis of studies of the development of the digital environment of educational institutions, including universities conducted by domestic scientists, shows the lack of demand or the limited use of modern educational technologies, digital tools, educational Internet services with the potential to create a comfortable environment for cooperation and interaction among all subjects of the educational process. In this regard, the formation of the university's digital educational environment is an urgent task of modernizing Russian education.

Based on this, the aim of the study is to substantiate the need for the formation of a digital educational environment of the university and determine the main directions

of its creation, taking into account current trends in the development of the education system in the digital economy and resource capabilities.

The methodological basis is a review of modern scientific publications on various aspects of the formation of the digital environment of educational institutions, including higher education (Akimova O., Babin E., Blinov V., Dvoretskaya I., Dulinov M., Esenina E., Karakozov S., Kushnir M., Sergeev I., Tarasov S., Maron A., Meng T., Uvarov A., Frumin I., Shcherbin M., Bowen U. and others) [1–12], legislative documents on these issues; own research results.

The study applies marketing, process, system, integrated, situational approaches; methods of logical, systemic, statistical and comparative analysis.

3 Discussion and Results

Under the digital educational environment [13], we consider "the totality of information systems, digital devices, sources, tools and services that are created and developed to ensure the operation of educational institutions and to solve problems arising during the preparation and implementation of the educational process" [14].

For its formation, it is necessary to understand students' requests, their requirements for educational services. In addition, knowledge of modern trends in the world and domestic markets, the requirements of society and the state for the competencies of a modern person as an active participant in public life in a digital economy are necessary. As well as consideration of already existing digital technologies, the experience of their application and the possibilities of introducing higher education into the educational process.

According to research conducted by McKinsey, Netology [15]; Research of the Russian Market of Online Education and Educational Technologies, [16], the following trends are observed in the global educational space:

- Increased demand for mass opens online courses with a simultaneous movement towards the globalization of online education using machine translation and speech recognition technologies;
- The struggle for leadership in the global ecosystem of educational technologies of IT giants: Apple, Amazon, Google, Microsoft, integrating their products into the activities of higher education institutions;
- Strengthening the role of video content- webinars, on-demand video in online education;
- Active use in the educational process by students of their own gadgets and other technical means—the concept of BYOD (bring your own device);
- Virtualization of training, primarily in the segment of applied specialties, using technologies of virtual, augmented, mixed reality (VR/AR/MR); use of technologies of virtual simulation of objects;

– Implementation of such educational models as: training based on project work (project-based learning); blended learning in higher education, combining traditional classroom, distance-digital; adaptive learning; gamification, training with entertainment, especially in demand in the business segment in corporate training; "Micro-learning", which is based on the development of educational material in "small portions"; ongoing learning (life-long learning).

Thus, today we are witnessing global processes of deep penetration of modern digital technologies, IT products in the field of education, changing approaches and requirements for the educational process.

The creation and development of digital educational space in our country today is also given great attention at the state level. Several documents regulate this field of activity:

– Federal Law "On Education in the Russian Federation" No. 273-FZ dated December 29, 2012 as amended in 2019;
– Decree of the President of the Russian Federation dated 09.05.2017 No. 203 "On the Strategy for the Development of the Information Society in the Russian Federation for 2017–2030" aims to create conditions in order to increase the availability of high-quality educational services using technology platforms for distance learning";
– Decree of the Government of the Russian Federation of December 26, 2017 N 1642 (as amended on March 29, 2019) "On approval of the state program of the Russian Federation "Development of education"(as amended and supplemented, entered into force on April 12, 2019), in which of the federal project "Digital educational environment" is the creation of conditions for the introduction by 2024 of a modern and secure digital educational environment that would ensure the formation of value for self-development and self-education among students of educational institutions of all types and levels by updating information and communication infrastructure, training, the establishment of the federal digital platform.

Thus, normative state documents focus on ensuring competitiveness and improving the quality of Russian education through the development of the digital environment of educational institutions.

Russian universities are actively involved in the formation of a digital educational space; Massive Open Online Courses is developing, the purpose of which is to make education open, flexible, convenient. About 400 online courses of Russian universities (HSE, Moscow Institute of Physics and Technology, St. Petersburg State University, Tomsk State University, Moscow Engineering Physics Institute, Moscow State University, St. Petersburg State University, Moscow State Institute of International Relations, Moscow State University, ITMO, Ural Federal University, NUST MISIS) are posted on the two largest international open educational platforms Coursera and edX.

Currently, there are more than 50 sites for online courses in Russian, the largest of them are the National Open Education Portal (465 courses, 16 developing universities), Stepik Platform (700 open online courses), and the educational project "Universarium" (199 courses), non-profit educational project "Lectorium" and others (data for February 2020).

From a marketing point of view, the placement of online courses by universities on such sites contributes to the achievement of various goals: increasing the visibility of the university, strengthening its brand and attracting new students; as well as improving the effectiveness of education due to the ability to integrate online courses in the educational process.

Another trend is new university models. Mail.ru, using the approaches of leading US training centers, founded Geek University online university. The specificity of the university is the deep development of modern professions and the guarantee of employment of graduates upon its successful completion.

There is a tendency to create collaborations with business partners in order to jointly solve scientific and practical problems in the development, testing of research and practice-oriented projects. For example, at the State University of Management at the Institute of Marketing, the "LabBee" laboratory was created in conjunction with "Vympelcom" (Beeline brand). The result of students' project activities is the development of original digital products, which also contribute to solving the problems of the development of the digital economy.

As a result, differentiated, individualized and personalized learning models based on the principles of the dominance of the learning process, accessibility, flexibility, and continuity of education for all categories of citizens become quite achievable, given that today, at the individual level, participants in the educational process are no longer satisfied with the old approaches. The low level of individualization in the educational system reduces the motivation and interest of students.

The new federal state educational standard sets the task for each student—to form the ability to manage their own teachings. Thus, the educational environment of higher education should meet the objectives of a digital society—to create conditions and the opportunity to develop along an individual educational path.

Universities are still quite fragmented in introducing digital educational technologies. The main problems are the lack of digital literacy of students and staff of the institution, including the faculty; in the absence of the necessary infrastructure and financial resources, especially in the regions.

In order to determine the level of awareness and attitudes of students towards digital tools, tools, educational technologies, a qualitative study was conducted in which students of the State University of Management 1–4 full-time students took part. Of the 200 students who took part in the survey to the question: "What educational platforms that host online courses are known to you", 11% of respondents said they did not know about such platforms.

The largest percentage of respondents are aware of the presence of platforms such as Lectorium (35%); Universarium (27%); the national portal "Open Education" (27%) and UNIWEB (20%). The same percentage was obtained in response to the question: "What educational platforms do you use for self-education?"

To the question: "What additional resources do you use for self-education?", 60% of the respondents named YouTube, 27%—the Internet encyclopedia with free content "Wikipedia", 10%—Instagram, 5%—"Yandex Zen".

According to the results of the study, students consider blended learning (a combination of online and offline learning) to be the best format for including online courses in the educational process of a university.

At the same time, when asked about the most preferred role of the teacher in the educational process, the guys noted that they would like to see the teacher as a mentor (50%), curator (40%), consultant (5%) on issues related to both with training and with "life issues."

The results showed that the developed digital environment of the university, which makes it possible to use digital technologies in the educational process, will, in the students' opinion, contribute to a better assimilation of the taught material (67%), an increase in interest in the discipline and activities (80%), and broadening the horizons (48%), time saving (22%).

Summarizing, we note that the guys are not sufficiently aware of the existing open educational platforms and online courses hosted on them. At the same time, they believe that classes using digital technologies are more interesting, high-quality, save time and expand their horizons. In addition, students would like to see in the teacher not only a translator of knowledge, but also a person who would help in life and difficult circumstances and inform on time about the possibility of training or retraining using digital and educational technologies.

As a result of the analysis and systematization of scientific works devoted to the studied problems [14], taking into account current trends in education, we have formulated priority tasks that need to be addressed, and, based on this, the main directions of development of the digital educational environment of the university are determined (Table 1).

The digital educational environment of the university is managed and dynamically developing. In its formation, it is necessary to understand the feasibility and possibilities of the most complete use of digital technologies in the educational process, their productive use in solving problems of increasing the effectiveness and quality of education.

4 Conclusions

In the conditions of the digital economy, the key to the effectiveness and competitiveness of higher education institutions is the creation of a digital educational environment of the university, which should be formed considering the principles of accessibility, flexibility, mobility, partnership, openness - go beyond the university.

The development of the university's digital educational environment should lead to qualitative changes: changes in the content, methods and organizational forms of working with students, and increase the effectiveness and quality of the educational

Table 1 Areas of activity for creating a digital educational environment of a university

Ways for the formation of the digital educational environment of the university	Solved tasks
University digital infrastructure development	– Effective management of an educational organization; – Providing access to modern digital technologies – Organization of affordable, mobile communication between participants in the educational process; – Posting the results of educational activities of students; – Organization and provision of timely feedback with students – Prompt decision of administrative issues; – Simplification of the interaction of participants in the educational process; – Providing access to an almost unlimited amount of digital educational and methodological materials
Development of digital educational and methodological complexes and new educational tools	Updating the methods and forms of educational work in order to increase its effectiveness and quality
Digital Assessment Development	Rapid assessment of the dynamics of the formation of the required competencies.
Implementation of educational technologies (learning with entertainment—gamification, distance learning, project-based learning, blended learning and other models	– Personalization of the educational process, implementation of the principles of flexibility, individualization, continuity of education; – Increasing effectiveness and efficiency of educational activities
Formation of digital literacy and digital culture	Building the ability to design and use digital technologies and tools in the educational process; – The formation of a culture of working with information, including information security
Formation of a network educational ecosystem (collaboration, business partnership)	– Formation of a continuing education platform; – Interaction of the educational organization with other organizations and business partners in the joint creation of innovative products in the implementation of projects of various kinds

process in accordance with the requirements of all interested parties (state, society, employers, citizens and other participants).

At the same time, in our opinion, the formed digital educational environment of the university will be a modern marketing tool - it will increase the demand for educational services, attract applicants for educational programs of undergraduate,

graduate and additional professional programs; It will contribute to creating a favorable image of the educational institution and will be associated with innovativeness, manufacturability, and the quality of the provision of educational services.

Based on the results of the study, the authors identified the following areas of formation of a competitive digital educational environment of a university:

- development of the institution's digital infrastructure, including the development of information services, the creation of information management systems, the development of network communication services, etc..;
- development of digital educational and methodological complexes and new educational work tools;
- implementation of relevant educational technologies (training with entertainment, distance learning, project-based learning, blended learning and other models).
- development of digital assessment;
- the formation of the participants of the educational process of digital literacy and digital culture;
- Formation of a network educational ecosystem (collaboration, business partnership).

The results can be used by higher education institutions in the formation of a digital educational environment and as areas for further research into the search for competitive advantages in the context of digitalization of society.

Digital Insurance as an Industry in the Digital Economy

Oksana A. Revzon, Maxim P. Pochekutov, and Alexey E. Barabanov

Abstract This article analyses the current state and directions of development of digital insurance as one of the branches of modern economy of the Russian Federation. Attention is paid to the increasing risks of cybercrime, the assessment of the amount of damage to such crimes is given, the protection of information data is considered. The most perspective branches of development of digital insurance are marked. At the same time, a view was expressed on the future of insurance as an autonomous industry. Risks are presented, including those related to the active creation of ecosystems by banks, which allow insurance operations to be carried out by banks' clients on their own, which, on the other hand, is a serious incentive for insurance development. The advantages of digital transformation and integration of insurance companies and services into the global digital ecosystem are described. New challenges that insurers may face in the transition to digital format are presented. Attention is paid not only to the need to make technological changes in insurance, but also to modernize relationships with customers. The potential of the Russian insurance market has been identified and tools for its implementation have been offered. There is a suggestion to expand the range of complex services provided. The main problems on the way of digital insurance development and possible steps for their solution have been identified.

1 Introduction

Speaking about digital insurance, first of all it is necessary to distinguish two directions in which its world development naturally proceeds: emergence of the new risks connected with information technologies and demanding comparable decisions, and also digitalization of insurance instruments directly, similar to other financial institutions.

According to the 9th annual Allianz Risk Barometer survey, published in 2020, about 39% of respondents (2718 experts from 102 countries and 22 industrial sectors) recognized data protection incidents as the main risk for doing business. Compared to 2013, when this type of risk was ranked 15th with 6% of votes, there has been a significant increase in concerns about cyberattacks and the financial losses caused by them in a short time. According to Joachim Mueller, CEO of AGCS, "cyber risk and climate change are two exceptional challenges that companies should address in the new decade" [1].

We are not only talking about single hacker attacks on private companies, but also about the work of entire organizations operating at the state level. In this regard, new types of risks arise and are replicated, ranging from simple failures of IT systems, data vulnerability to direct and indirect financial losses caused by fines and legal proceedings due to distortion of information.

2 Methodology

Today, the systematically arising risks that are the object of insurance are the following: failure in the system of online services, the existence of responsibility for errors that do not occur through the fault of the performer, and related to system failures, the risk of loss of reputation, third-party interference in the form of spamming content, or hacking and deliberate damage by hackers of user services.

According to experts' estimates, if five years ago losses from database violations were in the tens of thousands of dollars, now we should talk about the amounts at least twice as high. For example, the average amount of losses from cybercrime in the US in 2018 was $27.37 million [7]. Not surprisingly, many companies have begun to change their attitude toward such attacks and look for solutions to protect themselves.

V. Mikhnevich, one of the insurance directors of Allianz Insurance Company, for the Forbes website, referring to the data of Kaspersky Lab, claims that the average losses from cyberattacks are measured in tens of millions for quite large companies and about 2 million rubles are losses for representatives of small and medium businesses. And Russia accounts for about 9% of all recorded global cyberattacks, which brings our country to the 4th place in this kind of anti-rating [12].

In its review of the insurance market in Russia in 2019, KPMG offers individuals' property insurance (67% of votes) and cyber risks insurance (42% of votes) as the

most promising types of insurance in addition to life insurance with growth potential of more than 10% [5].

Therefore, it is far from groundless that, out of the six federal projects, "Information Security" takes its place with the budget of 30.2 billion rubles within the national program "Digital Economy of the Russian Federation" [8].

Another incentive for the development of digital insurance is the pressure from competing financial institutions—primarily banking groups. By collecting statistics on their customers, banks can easily generate a beautiful presentation for everyone: how much money they spent on food, shopping, filling up cars, which restaurants they visited and how many times they went to the cinema last year.

Having such information, banks are able to form targeted offers for a particular consumer of services in accordance with their personal preferences. And for such offers to reach their addressee digital technologies are needed.

Today, with the help of online banking you can not only execute a loan or open a deposit, but also make investments or issue insurance policies. Going abroad, it is no longer a problem to pay for insurance coverage at the same time as buying tickets.

Arseniy Poyarkov, a researcher at Forbes, believes that with the further development of digital economy, insurance as a separate area may lose its relevance. Insurers will have to prove their relevance by becoming part of the digital space and part of the interconnected ecosystems [10].

At the same time, insurance as a sector of the economy certainly cannot lose its relevance and great importance, especially in the digital economy. However, the question is being asked: is insurance useful by itself or should it be more logical and convenient to use it as a related service? Obviously, insurance companies can no longer remain as they existed. Insurers will have to either develop their own services to meet growing customer needs or integrate into global digital ecosystems.

Why are we gradually moving from a conventional economy to a digital one? In the first case, we can determine for ourselves the final costs of each direction, create patterns of behavior, establish causal relationships. Digitalization promises to minimize costs and a large number of connections, which is associated with the speed of change in business structures. In this aspect, one of the main advantages of digitalization is being implemented.

The digital transformation will undoubtedly expand the scope of insurance services, attracting the masses of population to insurance. Modern insurance will provide an opportunity not only to effectively compensate for losses at the onset of insurance events, but also significantly improve the quality of risk management. All these factors will have an extremely favorable impact on the development of the economy as a whole, and on improving the availability and quality of insurance services for users, and minimizing expenses of insurance companies.

Moreover, the active introduction of digital technologies, both existing and under development, will provide the insurance market with the possibility of uninterrupted risk insurance even in case of business chain breakage.

3 Results

Today, all industries are moving to digital standards. The volume of resources allocated for the full implementation of "Big Data", "blockchain" and other technologies has increased significantly. According to a report by Huawei and Oxford Economics [11], the estimate of return on investment in digital technology is almost 7 times higher than that on investment in non-digital technology over the past 30 years.

Digitalization of insurance should not be considered as a means of technological modernization as such, through the use of digital technologies insurance companies should solve new tasks in business. For example, the fact that digital currencies are no longer even in the near future, but in the present, clearly indicates the automatic emergence of a risk group associated with their use. The work on hedging and insurance of such risks can and should be carried out by insurers even against the interests of the banking industry. The potential of the insurance industry is very large, it is a real instrument of growth of capitalization of the country's economy.

The evolution of insurance into digital places the insured in the epicenter of the insurance system as a whole, thus contributing to the reduction of his risks, primarily due to the fact that the reserves of insurance companies are spent directly on operations and activities that level the risks. Digital insurance, above all, allows the policyholder (the insurance company's client) to build up their expenses, manage and plan their insurance expenses. The client can always reduce costs by taking certain measures to reduce the probability of an insured event. It is always possible to install an additional fire protection system to your home or office, conclude a contract with an outside property protection guard, etc.

Traditionally, the insurance company tries to increase the efficiency of resource allocation in all aspects and directions of its activity by all means: to reduce expenses in the field of document circulation, in the part of loss settlement, logistics, first of all, at the expense of optimization of organizational work which can be achieved by digital technologies. One way or another, all business processes of insurers are subject to digital upgrade, the purpose of which is directly aimed at improving the efficiency of the company. The transition to digital management allows companies operating in the insurance industry to apply a radically new technological toolkit to their work. The world-renowned international consulting company Ernst & Young conducted a study [3], which identified and systematized a number of new digital technologies designed to significantly simplify and improve the efficiency of business processing of insurers in general.

Below are some of the most important goals and objectives of insurance companies that optimize their operations through digitalization:

- the speed of interaction with the market,
- underwriting efficiency,
- sales productivity,
- cost reduction,
- the effectiveness of loss adjustment,
- customer experience management.

The following digital technologies of this functionality have a significant impact on all presented components [3]:

- voice biometrics,
- communication with the client through different channels of information exchange,
- using drones and satellites,
- working with "Big Data" analytics and "blockchain",
- the active use of the "Internet of Things".

According to the management of many insurers, digital, or as they are called, "cloud" technologies, artificial Intelligence, as well as technologies such as "blockchain", in the next few years will be crucial for companies that consider themselves modern [9].

The study by McKinsey [6] says that in no more than 10–12 years it is artificial intelligence and related technologies that will determine the future portrait of the insurer, determine the product line of insurance products and services. Above all, digitalization should speed up processes, make them more transparent and reliable. The time for formation and preparation of insurance policies will be counted in seconds, and this is taking into account the analysis of even more data about the policyholder than today. Blockchain will allow the authorization of payments to be carried out at lightning speed. Interaction between insurers and insurance companies will be carried out without the participation of insurance agents, brokers and other intermediaries and will be performed through the insurer's digital platform, which will allow underwriting the client in seconds. A separate conversation is the process of loss adjustment by the insurer, it is here that the main breakthrough should be made by means of the digital. Loss analysis, the time allocated for loss adjustment will decrease significantly. This will be facilitated by technologies for data collection and analysis: Internet of Things and drones will replace today's methods.

However, digital transformation does not only mean technological changes in existing business processes. It should be a new approach in understanding what, who and why the insurance company (insurer) should be for the client (insurer).

The conversion of traditional insurance into digital insurance should lead not so much to helping the client to plan and even minimize the cost of insurance, as to help minimize the risks as such. Obviously, policyholders themselves often do not fully understand the risks to which they, their family or their business are exposed. It is the insurers who are able to assess them qualitatively and quantitatively, including in terms of value for the client. Certainly, it is also necessary to take a set of measures for preventive minimization of these risks with assessment and calculation of probable insurance premium [4].

Digital insurance is first and foremost insurance for the client.

Two main aspects of the future insurer's activity can be described as follows: the first is the client with their risks, fears and needs; the second is the quality of service for this client. All that the client cares about, and most importantly, what they do not realize, but what potentially touches them based on their lifestyle, profession, business and individual preferences, behavior in the home and among colleagues

and much more. All this should be analyzed through numerous analytical systems and databases, including those based on artificial intelligence technologies. In this case, the service provided to the policyholder should be unobtrusive and accurately focused on the potential client. Obviously, it is not necessary to offer a person to insure a car or a country house if they do not have such property. But if a person has a country house and a snowmobile in the garage, they should be strongly advised to take out accident insurance, even if they assure that they use the vehicle only a couple of times a year. Because accident statistics on such vehicles may not be available to the average person, and insurers have this information and realize the risk.

Research by Ernst & Young suggests that 4/5 of the total number of policyholders already today would like to more actively use digital telecommunication channels with insurance companies, such as Internet bots in mobile applications, chat rooms, SMS-notifications, etc. Findings clearly show that communication between insurance companies and their customers should be concentrated on-line [2].

According to McKinsey, by 2025 digital ecosystems will generate up to sixty trillion dollars in total, which corresponds to thirty percent of global income. Already today, about 70% of the largest companies by capitalization are exclusively digital ecosystems (Facebook, Apple, Microsoft, Alibaba, Alphabet, Amazon, etc.) [6].

The largest ecosystem in Russia is definitely the Sberbank of Russia. It is its dominant role on the market that threatens its competitors in the banking sector in terms of apparent monopolization. Obviously, the insurance market is also directly in its sphere of interest, which the largest, so far, insurance market players should not forget about.

Insurance should not "be sidelined" on the way leading to the general digitalization of the country's economy, but should become part of this way and play a major role in the unified ecosystem of the modern digital state.

According to KPMG research, individual projects using new technologies are already bearing fruit and proving to be effective. For example, of those companies that use these technologies in the field of billing and underwriting, more than three-quarters confirm positive results. In the short term, most insurance companies agree to continue research and dissemination of new technologies. They expect that such investments should pay off in no more than five years [5].

4 Conclusion

Tax benefits will help to promote insurance services, in particular, life insurance—the possibility of a five-year policy to receive a 13% deduction annually from the amount of 120 thousand rubles. However, this benefit is not decisive yet. Firstly, it appeared relatively recently and not everyone knows about it, and secondly, the "compensable" limit of 120 thousand life insurance is divided with other social expenses of Russians (on healthcare, education, etc.).

Many experts believe that the Russian insurance market is underdeveloped and has a great potential, which at present remains underutilized.

In the short term, we can expect the following changes in the work of insurance companies:

1. Greater customer focus: the main indicator of the result will be the degree of satisfaction of policyholders. For this purpose, many companies will have to restructure the existing business model, including "cultural" restructuring and focusing from product to user.
2. In this regard, the satisfaction of requests and claims is assumed to be the priority and most important elements to maintain customer interest. Quick resolution of all issues creates a positive experience.
3. The insurance business should leave the existing models in the past to bring the service in line with current needs.
4. The main directions of insurance will be based on fully or almost fully automated insurance platforms. The experience of using CRM systems for more adequate management of customer relationships will be useful here.
5. Information and data, become the most important resource, so to speak, of the circulatory insurance system. The lack of accurate data can make it much more difficult and less effective not only for digital insurance, but also for insurance as a whole.

However, against the background of the general trend of digital economy development, domestic insurers themselves are quite optimistic in their assessments of their development and believe that their level of digitalization is quite in line with today's needs: more than a third of companies estimate this level to be around 30%. This was stated by A. Tsiganov (Head of the Department of Insurance and Social Sphere Economy of the Finance University under the Government of the Russian Federation) at the second all-Russian scientific-practical conference "First results and drivers of further development of digitalization of the insurance market in the Russian Federation". According to his words, the overwhelming number of insurers in their daily activities are now using Internet technologies to implement business processes (over 90% of votes). More than half of insurance companies' representatives vote for the use of Big Data technologies and just under half use the latest production technologies. 40% are already widely using wireless communication, 30% are using so-called artificial intelligence [13].

Alexander Tsiganov noted that the high share of internet sales of insurance services, especially in the segment of MTPL insurance, as well as the professional belonging of the majority of the insurers' representatives, who fill out the questionnaires, to the IT departments, could have influenced the high assessment of the level of digitalization of their own activities.

It would also be interesting to note from Tsiganov's speech that the low prevalence and applicability of digital programs in insurance is primarily due to the low level of digitalization of the country's economy as a whole. As the country develops in general, it will be possible to observe a natural demand for digital services in insurance as well. Problems with the availability of appropriate highly qualified specialists-developers of programs, as well as possible lack of attention on the part of insurers in terms of interaction with professional companies specializing in such

developments, their fairly high price at the initial stages, which require significant investment—all this is to be solved over time [13].

New digital technologies, as A. Tsiganov noted, are used by insurance companies in the sales of insurance services to the greatest extent, which is defined both by legislative norms and allows to quickly assess the economic efficiency of the implemented technologies. Also, a high share of new digital technologies is used in the process of communication with policyholders and in business settlement processes.

As a conclusion, it should be mentioned that despite the noted problems and restraining factors the potential for growth of digital insurance in Russia is huge, and the level of penetration of insurance services in Russia is gradually increasing. Diversification of supply, along with digitalization, also contributes to this. Many players focus on additional services. For example, accumulative life insurance policies these days often include the services of a tax consultant to help clients receive a tax deduction, or an educational concierge to quickly resolve any emerging issues in the field of education and development of children. In addition, medical services embedded in VHI and life insurance, such as comprehensive high-tech diagnostics based on the results of examination and tests, are being actively distributed. Interaction of people with insurance companies is no longer limited to receiving payment in case of emergency—insurers are increasingly trying on the role of a permanent assistant in solving a variety of everyday issues of clients. Many factors can accelerate the growth of the insurance market: the increase in financial literacy of both adults and children, the introduction of digital technologies, and further diversification of services, and strong marketing aimed at changing public opinion, awareness and recognition of a particular brand.

Digitalization of Distributed Technology Interest Clubs in Framework of the Agile Technique

Viktoriya V. Degtyareva and Anatoliy Yu. Korablev

Abstract The article has estimated the possible introduction of agile technique for management of interest club activities in arranging technology clubs as part of the National Technology Initiative in the digital economy. The authors have revealed the opportunities of interest club management against conventional forms. The advantages of using digital approaches in agile techniques for interest club management have been found and recommendations on the introduction of digital solutions in the technology club management have been developed.

Keywords Digital economy · Digitalization · Agile · Interest club activities · Innovation · Management

JEL Codes O10 · O30 · O32

1 Introduction

The club movement has historically been one of the technological drivers. Since the early twentieth century, many breakthrough ideas have been conceived within such clubs. A striking historical example is the establishment of the Central Aerohydrodynamic Institute on the basis of the Zhukovskiy club in 1918, which gave rise to Soviet aviation [1].

Nowadays, the club movement has gained a new purpose thanks to involvement as an independent movement in the National Technological Initiative (NTI). The goal of the STI clubs is to create an ecosystem in Russia to unite the innovators in the most promising technologies, large companies, and state corporations [2]. Thus, the club movement is an integrator of education, science, and business.

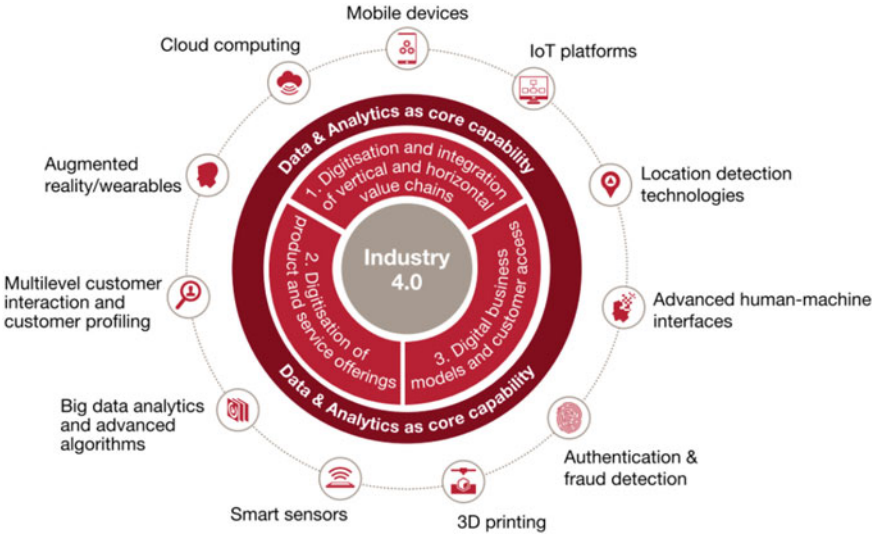

Fig. 1 Digital economy technologies [4]

In the understanding of the national technological initiative, the development of modern clubs is impossible without integration with the digital economy processes. The technologies referred to the "Digital Economy" [3] are associated with the key markets of the National Technology Initiative (Fig. 1).

At the same time, the management processes of technology clubs are often arranged without taking into account of digital economy peculiarities. If the club is headed by a technology innovator, the managerial processes that are essential for the establishment of a wide-scale and sustainable community of a particular club are often fall out of sight. If the club is commercial and its manager is profit-seeking, a strong contradiction arises between the goals of the NTI club movement and ones pursued by a particular commercial club.

1. Modern club activities can be based on a distributed principle. Remote communications technologies allow the club members to work at one project on a distant basis. In particular, this form of club activity makes it possible to pull together a multi-disciplinary team for the execution of innovative projects of real customers in the face of a shortage of school and university students' competences within the same educational institution or city [5].

The idea of club activities is concluded in the implementation of unique projects for the real sector of the economy. As understood by the National Technology Initiative, the result of the technology club performance is in the generation of innovative projects that can be useful to the real sector of the economy, or customized projects for club partners. Thus, the task of club management concerning the substance of the tasks to be solved is reduced to the innovative project management task.

Innovative projects can be efficiently managed with the help of an agile technique. The latter is built on 12 principles designed to manage small teams for the agile

development of innovative products [6]. One of the most popular agile techniques is SCRUM based on immediate feedback, continuous product improvement, and quick adaptation to changes [7].

The efficiency of agile project management techniques in the innovative design is proved by the example of the program "Participant of the Youth Scientific and Innovative Competition" ("UMNIK") of the SCRUM Foundation for the Promotion of Innovation and Project Management Technique [8]. According to the study, the development of innovative projects submitted to the UMNIK has become more efficient (by 30% on average) using the SCRUM technique.

The SCRUM-based projects "Information Technology" that have become number one in the UMNIK program succeeded in the medicine-related [9] and sports digitalization projects [10]. The authors of both projects underline a decisive role of agile technique for their projects.

Thus, the use of agile project management techniques allows raising the performance of project teams in the development of innovative projects [11].

At the same time, distributed teams working under the same project deal with some critical problems that negatively affect the success of project result generation. All problems can be classified depending on the causes of their occurrence [12]:

1. Strategic (problems concerning the utilization of existing resources; it often appears that the solutions under use are proprietary);
2. Project and process management (troubles in reconciling remote team members with each other);
3. Communications (challenges of developing efficient communication patterns);
4. Cultural (behavior, processes and technology contradictions);
5. Technical (an incompatibility of the data lay-outs and standards under application);
6. Security issues (remote transmission of information to be protected).

The above-listed groups of problems can hinder the representation of a distributed club model and, consequently, lower the potential complexity of the tasks to be solved by the club for the real sector of the economy.

The solution to each of these problems lies in the different branches of knowledge. In this paper, the authors suggest a possible method of solving the problem of project management of club activities through the digitalization of the club management processes.

2 Methodology

In the course of the study, the authors have employed universal scientific methods, including idealization and formalization, as well as observation, simulation, comparison, and abstraction.

The data source is three studies conducted by the Russian Venture Company jointly with Intel Russia [13]. The first study, "Makerism as a Socio-Economic

Phenomenon," reveals the content of technology innovator communities. The second one called "Technical creativity is a hobby or an industry. A study of innovator and technogeek communities" makes it possible to review the statistics of the most common problems that innovators face when arranging club activities. The third study "Maker communities of schoolchildren in Russia. Infrastructure and members, forms and topics" allow investigating infrastructure problems of clubs within the digital economy and developing effective solutions.

The experimental research platform was the Autonomous Non-Profit Organization for the Support of Project Activities "Youth Innovations" (ANpO "Youth Innovations"). The purpose of the above organization under articles of association is to provide services in design and innovation activities, in particular educational services for children and adults. Also, "Youth Innovations" holds technology clubs on neural networks and big data, mobile development. The topic of clubs is in line with the cross-cutting technologies of the National Technology Initiative.

Using ANpO "Youth Innovations" as an experimental site made it possible to win the audience of the clubs with the highly interested school and university students, to conduct experiments on the introduction of agile management techniques in club activities, as well as estimate the performance of distributed clubs using suggested approaches to management processes digitalization.

One of the problems of club performance is the lack of preferential tenancy conditions, as well as difficulties concerning the search for the partners who are aware of the opportunities and economic benefit of cooperation with the club communities [14]. Therefore, holding club activities in a distributed form, when the clubs mostly operate on a distant basis, is one of the solutions.

The research methodology assumed the launch of two clubs and each of them involved two streams. The topic of the first club covered such fields as artificial neural networks, pattern recognition, and machine learning. The topic of the second club was aimed at solving the current tasks of mobile application development. Each stream used the principles of a distributed club:

1. Clubs members gathered in person no more than one time every two weeks to discuss completed tasks and set new ones;
2. All the activities of club members were carried out on a remote principle, the tasks were independently solved by members on their equipment and with individual time management techniques.

In fact, under this approach SCRUM agile project management technique has been used. The sprint took two weeks. The sprint was planned and a retrospective was carried out in person at the general meeting of all club members. In the first stream of the clubs, no additional SCRUM process digitalization techniques hadn't been applied, the members of the project teams have independently determined the methods of communication, synchronization, and time management. The club manager did not tell the members about working techniques within SCRUM. When communicating with the first streams, the manager monitored the progress of tasks and answered the questions raised.

In the second stream of two circles, the manager worked with the groups in a different way. A special lesson was held with each of the project groups to inform of the main methods of work and communication within the SCRUM agile project management technique.

Also, for the second streams, a digital environment was developed to support all SCRUM processes. This environment included three key tools, such as Slack corporate messenger, Asana project management system, and a GitHub-based service repository for source code collaboration.

The application of a specialized Slack messenger has several reasons. A separate messenger for the club working tasks reduces distraction during communications against popular instant messengers or social networks as a platform for communication.

The Slack messenger supports the distribution of communications into topic-based channels, as well as the use of hashtags. This approach allows for the pattering of information and a quick search for the necessary facts when working on the project.

The quick integration of bots into Slack messenger enabled the introduction of gamification elements of working on the project within club activities. In particular, a slack bot, which gave the rewards to the members depending on their activity has been launched in the framework of the specified clubs. If the member did not take part in the club for a long time, then the balance of the bonus account declined. Upon completion of the project, an auction where the members could win various prizes and souvenirs from club managers was held. The gamification is important from the standpoint of holding the audience, since the introduction of game elements, especially for school and university students, allows increasing their incentives for participation in the club activities [15] and preserving their loyalty to a particular club community.

Using GitHub as a tool for collaborative software development allowed members to avoid common problems concerning distributed software development. Among these problems are complicated synchronization of software versions, a version system arrangement, and a single interface for the interconnection of various components of a software product under development.

To evaluate the performance of technology club management digitalization, we compared various steams of club activities carried out without and with the use of digital tools.

There are several models for the evaluation of management performance. As for innovative enterprises, there is an opportunity to make a separate evaluation of innovative and technological capacity [16]. However, the clubs mostly pursue social goals, i.e. getting an educational result for the members, therefore, we didn't evaluate the economic performances of clubs with different approaches to digitalization.

The comparison was made in accordance with criteria typical for technology clubs:

1. The completion degree of the product result;
2. The volume of the knowledge base accumulated by project teams after working on the project;

3. The establishment of a sustainable project team ready to solve practical tasks.

Evaluation in terms of the completion degree relied on the estimates by experts who represent the club's industrial partners. Working on the project, the members should make up their knowledge base, a collection of new data to generate a product result. The sustainability of the project team was assessed by the feedback of club members and their willingness to work gain within this project team.

3 Findings

For assessment of the completion degree of the product result, we engaged the experts among the partners of the ANpO "Youth Innovations" and asked them to evaluate the projects by three criteria:

1. The practicability of the final product in real tasks;
2. Application of technologies corresponding to key areas of the National Technology Initiative;
3. The completion of the tasks posed.

Each criterion was evaluated on a ten-point scale. We have employed digitalization methods only in stream 2.

The evaluation outcomes of two streams referring to club "Artificial Neural Networks" are presented in Table 1.

The evaluation outcomes of two streams referring to the Mobile Development club are shown in Table 2.

After experts have evaluated the completion of the product result, we can see several dependencies:

Table 1 Expert estimates of the Artificial Neural Networks club

	Expert 1			Expert 2			Expert 3			Total		
Criterion number	1	2	3	1	2	3	1	2	3	1	2	3
Stream 1	3	8	5	7	10	6	2	7	4	12	25	15
Stream 2	6	8	6	9	10	7	6	8	7	21	26	20

Table 2 Expert estimates of mobile development club

	Expert 1			Expert 2			Expert 3			Total		
Criterion number	1	2	3	1	2	3	1	2	3	1	2	3
Stream 1	8	5	7	8	6	9	7	4	8	23	15	24
Stream 2	9	5	8	9	7	10	8	3	9	26	15	27

1. Stream 2 (using digitalization methods) in both clubs achieved the best results in terms of practicability of the final product in real activities and completeness of the tasks posed.
2. The application of digital technologies or their rejection does not affect the choice of technologies that have been used by different streams.
3. The difference between the stream taking to digitalization and the stream rejecting it is stronger in the club "Artificial Neural Networks", which indicates that digitalization is more pronounced when it concerns more sophisticated technologies.

When working on projects, the club members have been supposed to fill in their tabular knowledge base with three fields (challenge, solution, and the source of information). Each stream of the clubs filled in its knowledge base. After work on the projects was finished, the club managers evaluated the volume and quality of knowledge bases (presented in Table 3).

Relying on the evaluation outcomes of the final knowledge bases, we can conclude that the quality of the knowledge base appeared to be higher in the second streams

Table 3 The quality assurance of the knowledge base by club managers

Interest club	Stream	Number of solutions described	Comment of the club manager
Topic "Artificial Neural Networks"	1	16	All the main problems arising in working on the project are presented, the method of solution is described in brief, links to information sources are correct
	2	23	All the main problems arising in working on the project; for some problems, the description includes the source code and several solutions, links to information sources are correct
Topic "Mobile Development"	1	8	All the problems described are of current importance, the description is quite detailed, the links provided contain more extended information and solution options
	2	9	All the problems addressed are topical, the description is detailed (include examples of source code), the links provided contain more substantive information and solutions

of the club (using digitalization) and analysis of the problems was multiparameter and extensive. At the same time, the difference between a stream using digitalization and one rejecting it is more striking in "Artificial Neural Networks", which is a more complicated topic from a technological point of view.

After completing work on the projects, the club members were invited to fill out a feedback form. Among the questions was: "Would you like to work again with the same project team?"

The survey results for the "Artificial Neural Networks" club are shown in Fig. 2.

The survey results for "Mobile Development" club are presented in Fig. 3.

From the presented figures, it is impossible to draw a conclusion about the impact of the digitalization techniques under application on the willingness of club members to work again with the same project team. As for this study, most of the club members,

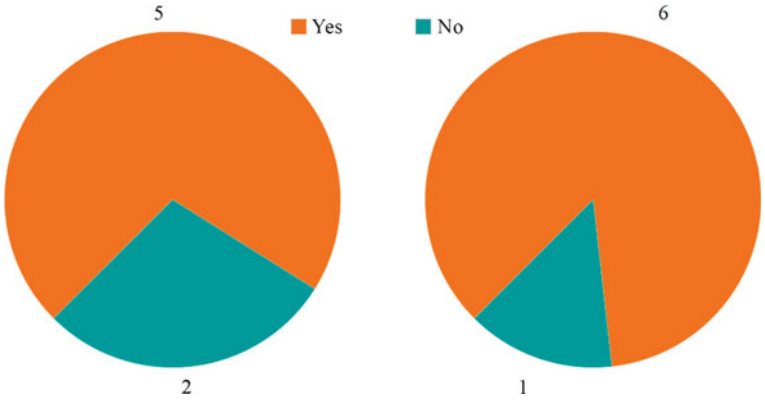

Fig. 2 Survey results for "Artificial Neural Network" club

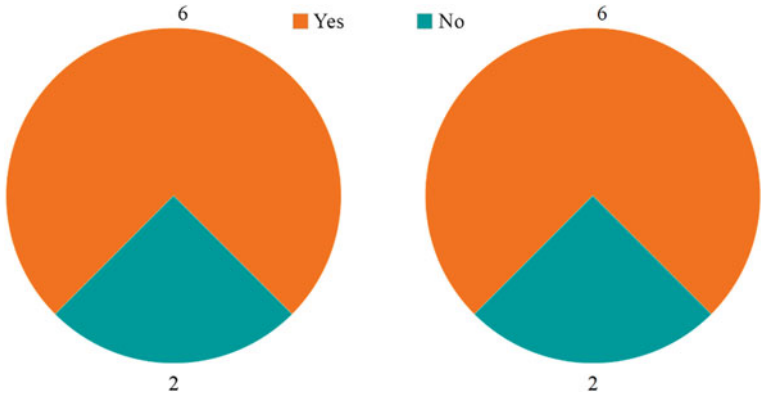

Fig. 3 The survey results for "Mobile Development" club

regardless of topic and stream, showed a willingness to work again with the same project teams.

4 Conclusions

As a result, we can draw several conclusions and recommendations on the introduction of digitalization techniques of agile management in the activities of technology clubs:

1. The more complex the topic of the technology club, the higher the performance of digitalization techniques;
2. The introduction of digitalization techniques is most reasonable in the clubs aimed at generating a real product result that can be useful for partner companies;
3. The introduction of digitalization techniques is viable if the club is intended to get an educational result and draw this result by the members when working on the project.

Allocation of Zones with Accelerated Development in the Region

Irina V. Filimonenko, Zoya A. Vasilyeva, Anastasiya N. Rusina, and Olga V. Karpycheva

Abstract The relevance of identifying accelerated development zones in the region's economy to reduce the gaps between the supply and demand parameters in the labor markets is explained by the need to determine the lists of professional competencies and professions for which there is currently no generated demand from business. To reduce the level of uncertainty in solving the problem, it is advisable to localize the area of the search for the expected changes in the demand for professional competencies of labor resources in those areas of the economy where organizational, technological, marketing and other types of innovations will be introduced. The aim of the study is to develop an algorithm for identifying areas of accelerated development in the region. Based on the content analysis of scientific publications on the study of the structure of the regional economy, the authors divided the concepts of "economy sector" and "accelerated development zone". Characteristics are identified that allow identifying accelerated development zones by spatial distribution in the region, belonging to the type of economic activity, technological efficiency and investment activity. Based on multicriteria selection, the article proposes an algorithm for identifying areas of accelerated development in sectors of the region's economy, the staffing needs of which will be reoriented to new professional competencies. On the example of the Krasnoyarsk Territory, the proposed algorithm was tested, accelerated development zones were established for macro-regions and types of economic activity, quantitative characteristics of labor resources were determined for which changes in business needs with respect to professional competencies are most likely.

1 Introduction

The relevance of the study is due to the priorities of technological, innovative and digital development of the economy, as a result of which the needs of the business are changing in relation to the professional competencies of employees, the uncertainty of forecasting the future needs of the economy in labor resources increases, and the imbalances in supply and demand in regional labor markets increase. Business representatives note that the shortage of specialists with the necessary characteristics is now becoming a mass phenomenon in the economic space of Russia [1–4]. In this trend, qualitative discrepancies in the competencies of the labor force, including soft-skills, to the needs of the business are increasingly being highlighted.

The solution to the problem is complicated by the uneven nature of the development of the economy in the regions of Russia, including spatial development, innovative activity of industries, the occurrence of imbalances between the parameters of demand and supply of professional competencies in labor markets. One of the possible ways to bridge the gaps in the structure of the supply of professional competencies of labor resources and, as a result, meet the needs of business entities is to diagnose the needs of the economy in relation to new and most demanded existing professions, new and priority professional competencies. Diagnostics will help determine the structure of clusters of professional competencies in those sectors and local zones of the economy where business needs change at an accelerated pace. Therefore, the problem of identifying accelerated development zones in the region with the aim of modeling clusters of professional competencies is of particular importance.

The aim of the study is to develop an algorithm for identifying areas of accelerated development in the region.

2 Methodology

To achieve this goal, the authors developed a system-structural approach to the study, which consists in the separation of the concepts of “economic sector” and “zone of accelerated development”; highlighting characteristics that allow identifying a zone with active processes of technological and innovative development; development of identification criteria and an algorithm for identifying areas of accelerated development in the region.

Since current priorities of socio-economic development are based on the transfer of technological innovations or the development and implementation of parent technologies in the sectors of the region's basic specialization, as well as on the development and implementation of new technologies in the innovation sector of the economy, "accelerated development zones" should be identified in these sectors of the economy (high-tech innovative) [5, 6].

Under the sector of the economy refers to the part of economic activity, characterized by certain features that allow you to distinguish it from other parts of economic activity for analytical purposes [7]. The selection of economic sectors for commodity regions is based on the use of statistical data on types of economic activity. Moreover, characteristics (products, prices, technological structure, production factors) were used as criteria, the combination of which allows revealing the main purpose of the sector from the position of market parameters (aggregate supply and demand) used in the international economy [5, 8–10].

As the study showed, the characteristics of the gaps between demand and supply of professional competencies (PC) fundamentally differ by sectors of the region's economy:

- In the traditional sector of the economy, gaps are characterized by a change in the quantitative parameters of demand between existing professions and existing clusters of professional competencies;
- In the high-tech sector, gaps are characterized by a change in the quantitative parameters of demand between existing professions for which clusters of professional competencies change (expanding the list of professional competencies);
- In the innovation sector, gaps are characterized by changes in the quantitative and qualitative parameters of demand as a result of reorientation to new professions and new clusters of professional competencies.

Due to the high differentiation of spatial development in the regions of the Russian Federation, it is impossible to expect that the innovative activity of business and the intensity of development of high-tech industries across groups of enterprises belonging to the same type of economic activity and the economic sector (high-tech, innovative) located in different municipalities of the region will be the same high.

This gives reason to believe that zones of "accelerated development" are formed in the sectors of the region's economy and are distinguished as territories with a high concentration of financial and organizational resources, which allow achieving significant economic results in the implementation of promising areas of regional development. Consequently, in the "zones of accelerated development" are located (or are planned to be placed) production with the latest technologies and technical and economic advantages compared to traditional technologies in the form of economic activity, which changes the needs of the economy and business in relation to the professional competencies of the labor force.

To identify the "zones of accelerated development" in the economy of the region we will use the following characteristics:

- *Location*—the boundary of the location of the macro-district or municipality in whose territory the "zone of accelerated development" is located;
- *Economic affiliation*—affiliation of the zone to the sector of the economy and type of economic activity;
- *Technological efficiency*—belonging to industry enterprises that use technologies that have novelty and technical and economic advantages compared to traditional technologies by type of economic activity in the region;
- *Investment activity*—the presence of investment projects implemented in the zone of "accelerated development".

The intersection of these characteristics will allow us to identify the zone of "accelerated development" in the region, taking into account the coherence according to the criteria of spatial location, economic affiliation and invested activity.

The procedures for identifying "zones of accelerated development" in the region's economy are based on the following criteria:

- technological efficiency (Tef_{ij}) of the group of enterprises of the municipality (i) related to the type of economic activity (j), calculated by the formula:

$$\text{Tef}_{ij} = d_{ij}/k_{ij}, \tag{1}$$

In which d_{ij}—is the proportion of the municipality (i) in the volume of products shipped by type of economic activity (j); k_{ij}—the proportion of the municipality (i) in the number of people employed in the production of products by type of economic activity (j);

- investment activity (Ipr_{ij}) of the enterprises of the municipality (i) related to the type of economic activity (j), determined on the basis of the binary variable model:

$$Ipr_{ij} = \{1, \text{if } Ipr_{ij} > 0;\ 0, \text{if } Ipr_{ij} = 0\}, \tag{2}$$

In which Ipr_{ij} is the number of investment projects accepted for implementation in the municipality (i) by type of economic activity (j).

The algorithm for identifying "zones of accelerated development" in the region's economy includes three stages (Fig. 1):

Stage 1. Diagnostics of sectors in the region's economy (traditional, high-tech, innovative), with the potential to form new requirements in relation to the professional competencies of the workforce.

The procedure for diagnosing sectors in the region's economy uses consistent statistical groupings of the totality of types of economic activity by indicators such as labor productivity; the amount of costs in technological innovation; the amount of costs for information and communication technologies. Based on the identification

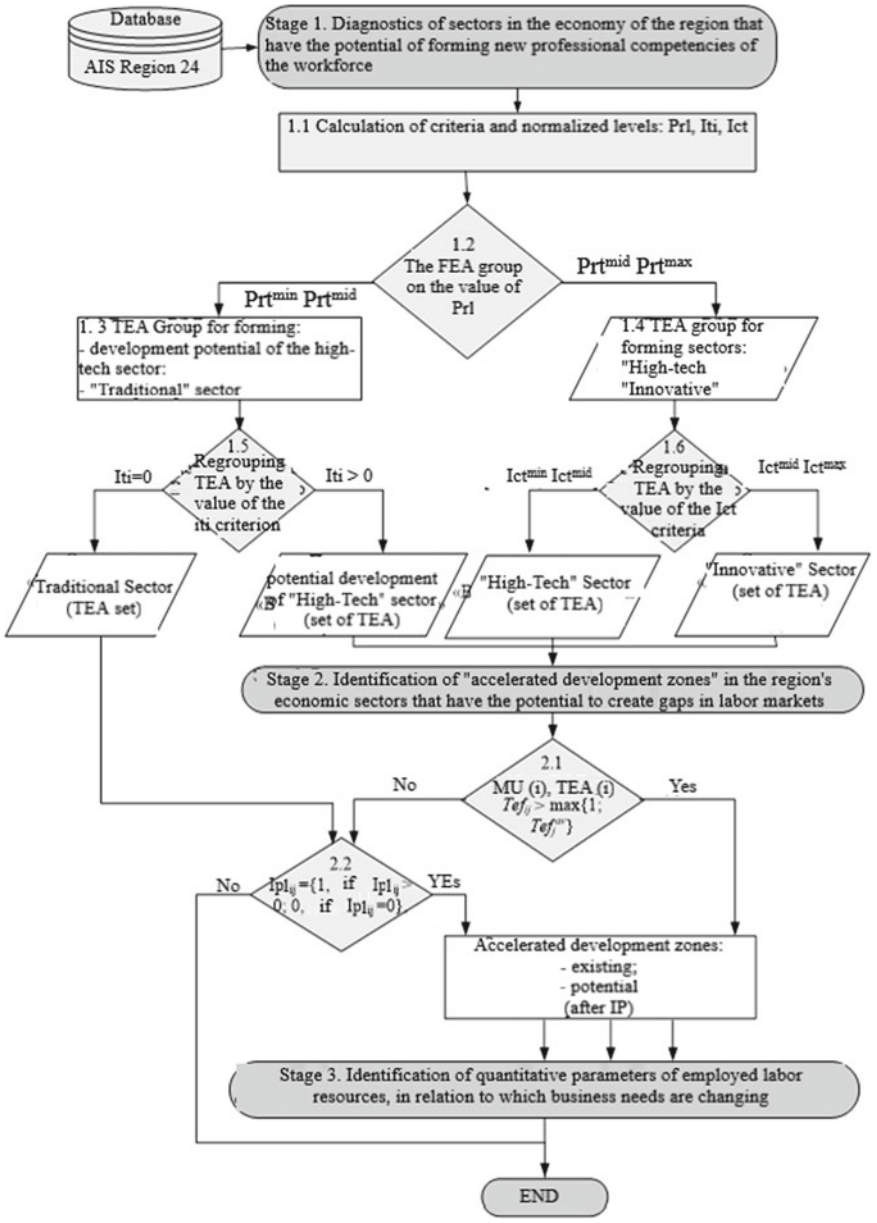

Fig. 1 Algorithm for allocating zones of accelerated development in the region's economy. **Notation Used**: Prl—labor productivity, Iti—investing in technology innovation, Ict—investments in information and communication technologies, IP—investment project, MU—municipal unit, TEA—type of economic activity

of group differences in the values of indicators, taking into account the standard deviation, the composition of sectors is determined by type of economic activity.

Thus, the first stage of the algorithm makes it possible to determine the lists of types of economic activity from the high-tech and innovative sectors of the economy that have the potential to formulate new requirements for the professional competencies of the workforce.

Stage 2. The identification of "zones of accelerated development" in the sectors of the region's economy that have the potential to create gaps in labor markets as a result of changing business needs in relation to the professional competencies of the workforce.

At this stage, the allocation of economic zones and labor markets is carried out at the level of municipalities in the region. For each type of economic activity (j) in the sectors of the region's economy, based on calculations of the structure of volumes of shipped products (d_{ij}) and the structure of the number of employees (k_{ij}), taking into account the spatial distribution of economic resources, the criterion of technological efficiency (Formula 1) and the criterion of investment activity (Formula 2) for each municipality (i). Fulfillment of the conditions (Formula 3) will make it possible to identify "zones of accelerated development" in the sectors of the region's economy:

$$\text{if } Tef_{ij} > \max\{1;\ Tef_j^{av}\} \text{ or } Ipr_{ij} = 1. \tag{3}$$

Since the selected economic zones are characterized by high technological efficiency and/or the presence of investment projects accepted for implementation, this indicates the use of technologies that have novelty and technical and economic advantages compared to traditional technologies used by enterprises by type of economic activity (j) as a whole region. Consequently, in the labor markets of these economic zones, there is a high probability of a change in the business needs for the professional competencies of the workforce and the formation of gaps between the supply and demand parameters. And, therefore, the second stage of the algorithm makes it possible to determine the lists of "zones of accelerated development", in the labor markets of which new requirements are formed in relation to the professional competencies of the workforce.

3. *Identification of quantitative parameters of the employed labor resources, in relation to the professional competencies of which the needs of the business are changing.*

Since, for selected economic zones, spatial (based on municipalities) and economic (based on the type of economic activity) borders are relatively easily established, this allows us to estimate the quantitative parameters of the employed labor resources based on existing statistics, with respect to their professional competencies there is a high probability of changing business needs. The assessment is made on the basis of determining the total share of employed workers (k_{ij}) for "accelerated development zones" corresponding to the type of economic activity (j).

The study of qualitative changes in business needs relative to the professional competencies of the workforce is based on the results of a content analysis of strategic

documents and programs for the socio-economic, technological and innovative development of the region, the punitive need for investment projects; Foresight studies of representatives of business, education and science. As a result, for each "zone of accelerated development", a list of promising and new professional competencies for existing professions is compiled, the development of which is based on existing educational programs, as well as a list of new professional competencies and new professions that require the opening of new educational programs [8, 11].

3 Results

The testing of the algorithm for identifying "zones of accelerated development" in the region was carried out on the basis of the Strategy for the socio-economic development of the Krasnoyarsk Territory until 2030; The industrial policy concept of the Krasnoyarsk Territory until 2030 [12, 13]. The following results are obtained.

1. The lists of types and subspecies of economic activity (in accordance with the Russian National Classifier of Economic Activities 2019) for the sectors of the region's economy for short-term (for 2020) and medium-term (until 2025) development periods are determined.

In 2020, the high-tech sector of the economy of the Krasnoyarsk Territory includes 4 subsections of economic activity, including: B-05: Coal mining; B-06: Crude oil and natural gas production; B-09: Provision of mining services; C-24: Metallurgical industry. In the same period, in the traditional sector - 42 sections and subsections of economic activity.

2. The differences between the high-tech and traditional sectors of the economy in terms of basic indicators are established (Fig. 2).

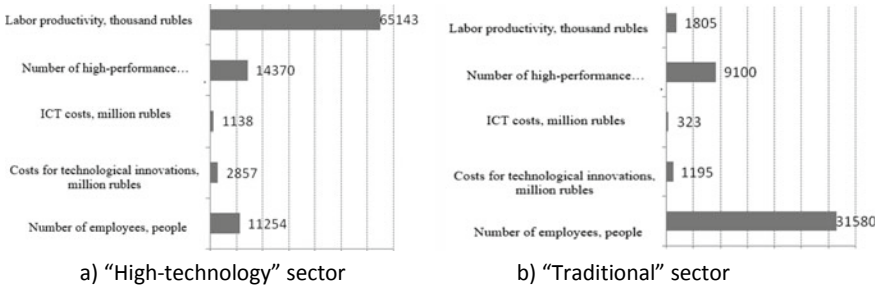

Fig. 2 Key characteristics of the Krasnoyarsk territory's economic sectors in 2019 for diagnostics of promising labor markets

For example, an analysis of differences in the level of *labor productivity* in 2019 showed that the average value of this indicator for the high-tech sector of the economy is 36 times higher than that of the traditional technology sector and twice as high as the economy of the Krasnoyarsk Territory as a whole.

Similar results were found in terms of:

- *Costs of technological innovations* (in the high-tech sector of the economy higher than in the traditional sector by 2.4 times);
- *The cost of information and communication technologies* (in the high-tech sector of the economy is higher than in the traditional sector by 3.5 times);
- *The number of high-tech jobs* (1.6 times higher in the high-tech sector of the economy than in the traditional sector).

At the same time, the number of employees in the high-tech sector of the economy is less than in the traditional sector by 2.8 times.

3. The dynamics of the sectoral composition of the high-tech sector of the economy of the Krasnoyarsk Territory is determined taking into account the investment nature of the costs of technological innovations and the expected return in future periods of development.

4. "Accelerated growth zones" have been identified in the Krasnoyarsk Territory with a high probability of changing business needs for existing professions (professional competencies of the labor force) in the high-tech sector of the economy or with a high potential for the formation of clusters of new professional competencies for new professions of the future in the high-tech and innovative sectors.

In *2019,* the formation of "accelerated development zones" for the Krasnoyarsk territory is associated with the development of raw materials industries:

- Coal mining (districts: Sharypovsky, Partizansky, Rybinsky; Borodino, etc.);
- Production of crude oil and natural gas (Turukhansky district);
- Metallurgical production (Norilsk, Krasnoyarsk);
- The provision of services in the field of mining (Krasnoyarsk, Evenki Autonomous Area).

In 2019, "accelerated development zones" were allocated in 8 municipalities of the Krasnoyarsk Territory. In 2020, development in these zones will continue on the basis of three investment projects: Development of the Yurubcheno-Tokhomskoye field (Evenki AA); Completion of the construction of the rolling complex and the smelting and foundry section of KraMZ LLC (Krasnoyarsk); Construction of the Boguchansky aluminum plant (Boguchansky district).

In the period of 2020–2022 zones of accelerated labor growth will develop in 10 municipalities of the region. Their development is facilitated by the implementation

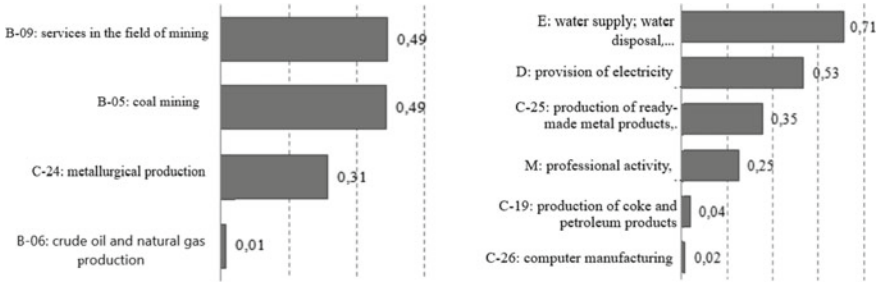

Fig. 3 Specific shares of workers employed in "zones of accelerated development" by TEA of high-tech sectors of the Krasnoyarsk Territory

of investment projects, among which the most significant for the region are: IP Development of the first launch complex of Kuyumbinsky (Evenki Autonomous Area); Hydrocracking and petroleum coke production complex (Bolsheuluysky district); Construction of the third power unit "Berezovskaya state district power station" (Sharypovsky district), etc.

5. The quantitative parameters of the employed labor resources are determined by type of economic activity, with respect to the professional competencies of which changes in business requirements are expected (Fig. 3):

- In 2019, the specific share of labor resources employed in the areas of "accelerated development" of the high-tech sector varied between four types of economic activity from 30 to 50%;
- In 2020–2022. the number of employees in the "zones of accelerated development" will increase due to the expansion of the high-tech sector of the economy due to such foreign economic activities as "Water supply, sanitation, waste collection and disposal" and "Provision of electric energy, gas and steam, air conditioning", etc. labor resources in the "zones of accelerated development" of the high-tech sector of the economy for six types of economic activity will be from 20 to 70%.

4 Conclusion

Thus, the use of the methodology for diagnosing zones of "accelerated development" based on a combination of quantitative and qualitative research methods allows us to identify local zones in the region's economy, on the labor markets of which changes in business requirements are expected with respect to professional competencies of the workforce. These processes are interrelated with the priorities of the socio-economic development of the region and are aimed at the scientific justification and narrowing of research areas to solve the following methodological problems: measuring the

gaps between demand and supply of professional competencies of labor resources; building a risk map of regional labor markets; the formation of clusters of professional competencies of existing and new professions in the sectors of the region's economy.

The results obtained provide the basis for the next stage of research aimed at building a risk map of regional labor markets; measuring the gaps between supply and demand of professional competencies of labor resources; the formation of clusters of professional competencies for priority and new professions in the sectors of the region's economy.

Regional Housing Policy in Enhancing the Growth of the Socio-economic Space of Urban Agglomerations

Sergey A. Korostin and Igor A. Grishin

Abstract **Subject**. The paper examines the impact of regional housing policy on the transformation of urban agglomeration space. **Purpose**. Identification of patterns, forms, methods and features of transformation of housing in the socio-economic space of urban agglomerations. **Methodology**. The research was carried out on the basis of methods of spatial and morphological analysis of regional socio-economic development, logical and graphic modeling. **Results**. In the work, the logic, character and tools of housing policy used to form new growth poles in the area of urban agglomerations were revealed on the basis of systematization of theoretical and practical approaches to the activation of socio-economic development of territories. As a result of the analysis of the mechanism of formation of new centers (cores) of economic activity of the regional space, a graphic model of distribution of centripetal and centrifugal forces of urbanization in relation to housing policy, which stimulates the socio-economic development of urban agglomeration in the process of its growth by building up the regional periphery with modern housing and modernization of the housing stock was constructed. **Conclusion**. The results achieved in this work are part of the organizational and methodological support of housing policy in the region, aimed at modernizing its socio-economic space through targeting polycentric model of urban agglomeration development. The findings, approaches, classifications, algorithms and generalizations obtained, which are considered as efforts to increase the toolkit of housing policy of a region, make it possible to design the development of its space with set parameters, such as: the structure of the region's economy, investment attractiveness, social and economic potential, the level of infrastructure development, the degree of urbanization of the territory, the share of economically active population, the reproduction of human capital, comfort of life, availability and accessibility of housing, and population influx.

1 Introduction

The evolution of the system of state structure, public organization and economic structure at the territorial level is expressed in the change of approaches to the socio-economic development of regional space. Traditionally sustainable production, trade and other cooperative relations that once formed the structure of regional economy and determined the balance of its socio-economic sphere inevitably change under the influence of external and internal factors. In addition to adapting to the direction and rhythms of the region's socio-economic processes, its housing policy updates its implementation methods and tools to improve the availability and quality of housing in the region.

Modernization of the housing sector activates the region's economy directly (stimulation of the housing sector) and indirectly (support of related industries and activities), increasing business activity, improving the investment climate and job growth. Attraction of additional resources in housing construction and related sectors, which determines the territorial development of the business and the increase of the gross regional product, transforms the housing policy into an effective instrument of the regional economic mechanism.

2 Methodology

The methodology of the work is composed of general scientific and specific methods that allow to recognize and systematize the regularities and characteristics of housing development in urban agglomerations. Comparative, logical, morphological, structural and functional analysis, as well as methods of simulation and graphical modeling are used to study the problem field.

3 Results

Regional socio-economic space covering agglomerations (urban and industrial), urban-type settlements, rural settlements, industrial and agricultural lands have various degrees of urbanization that change according to the regional development

vector. Urban settlements forming the socio-economic frame of the region are characterized by their own structure of spatial organization, which is expressed in the historically established type of layout and development [1].

The development of industrial capital has determined the trend of fundamental changes in the spatial organization of the urban environment that occurred during the twentieth century. In its first half, the transition from infill development to urban block planning and zoning was completed, and the second half is associated with the use of the industrial method of housing construction with a great level of walkability of infrastructure objects [2].

A significant increase at the turn of the 20th and twenty-first centuries in the share of the service sector as a sector of the urban economy predetermined the formation of new economic cores as centers of business activity in the regions, related mainly to the sphere of circulation and consumption growth [3]. The influx of population from the rural periphery into the new economic cores has increased the degree of urbanization of the regions and triggered the development of urban agglomerations as the focus of innovation-oriented transformations of the regional economic space [4].

The accumulation of economic resources in the administrative and economic centers of the region inevitably leads to higher development rates in suburbs, often becoming new growth poles. The socio-economic frame of a region built in this way acquires a network structure, especially in the process of joining with other agglomerations or transforming into inter-regional megalopolises [5].

In the process of urban agglomerations' growth and merging, cooperative ties of economic entities turn into integration forms of interaction over time, which increase transport flows caused by business trips, cargo transportation and commuting of the population. The creation of high-tech transport infrastructure increases the attractiveness of the region through improved access to transport corridors, in the direction of which the development of the free regional space has a high economic potential.

Construction of industrial, commercial and residential real estate fills the internal space of the built-up regional frame, feeding the emerging economic cores, concentrating around labor, economic, recreational and other resources. The resulting polycentricity of urban agglomerations rationalizes the placement of factors of production within the borders of socio-economic space, where most of the gross regional product is created, which provides a wide choice of spatial models of development [6].

The analysis of modern practice of regional space development allows to understand adequately the possibilities and level of applicability of the existing models of socio-economic development of the territory: territorial and industrial complexes, growth poles, special economic zones, development of depressed territories, technopoles, clusters [7]. Housing policy as a component of any regional development model is based on its specifics (specialization, infrastructure, economic potential, demography, living standards, location, natural resources, etc.) in order to develop an optimal strategy for providing the population with comfortable housing by increasing housing construction, stimulating the regional real estate market, increasing housing availability.

The growth poles, being a localized and connected common infrastructure group of enterprises of different branches of the regional complex, jointly achieve higher dynamics of development against the regional average due to the effects of agglomeration and urbanization. The main purpose of the growth poles is to "detonate" the urban economy to start its intensification in order to spread this process beyond the previous borders of urban agglomerations and to cover large areas of regional space, creating new growth poles there. The conceptual idea of "growth poles" is based on the diffusion of innovations generated by the most advanced sectors, which are the drivers of the region's economy capable of creating conditions for their own and related sectors' growth with subsequent transition to social and economic progress throughout the regional space [8].

Along with the group of leading enterprises in the region's economy, a localized and economically developed territory with high innovation activity spreading beyond its limits to the economically passive part of the regional space can be considered as a growth pole. Considering both sources of "detonation" of regional economy—the most developed groups of enterprises and localized territories—formation of growth poles in the area of urban agglomerations is imperative. Therefore, it is more reasonable to consider localized enterprises and sectors as "poles", and urban agglomerations or their areas as "centers or cores" of regional economic growth [9].

The heterogeneity of the regional space is a necessary condition for the emergence of poles and growth centers, where the highest socio-economic potential is generated in and around the urban agglomeration centripetal and centrifugal forces that change as they move away from it. Business impulses coming from different growth poles interfere in the regional space, creating zones of urbanization development [10].

The economic aspect of urbanization is clearly expressed through the phenomenon of concentration of enterprises of the leading sectors of the regional economy on the territory of urban agglomerations, and the social aspect is preferable to consider on the example of housing development in the process of formation of regional growth poles. Growing economic activity contributes to job growth and increases demand for labour resources, which leads to an increase in wages and living standards of the population ready to improve their housing conditions by purchasing affordable and comfortable housing built near the new growth poles [11].

The polarization of socio-economic space as a result of the disproportionate regional development is the main reason for the increasing inequality in living standards between relatively small urban agglomerations and the technologically lagging periphery of the region, which acts as a source of resources for urban growth in exchange for the transfer of social innovation. According to the classical model of J. Thuenen, the smaller the radius describing the limits of space around the center (core), the more positive impact this part of periphery receives from urban agglomeration [12].

According to G. Friedman's model, the regional space is structurally divided into cores and peripheries, which interact by moving goods, capital, technology, labour, information [13]. Bilateral flows of factors of production generate the diffusion of innovations needed to regenerate the core and maintain its links with the periphery,

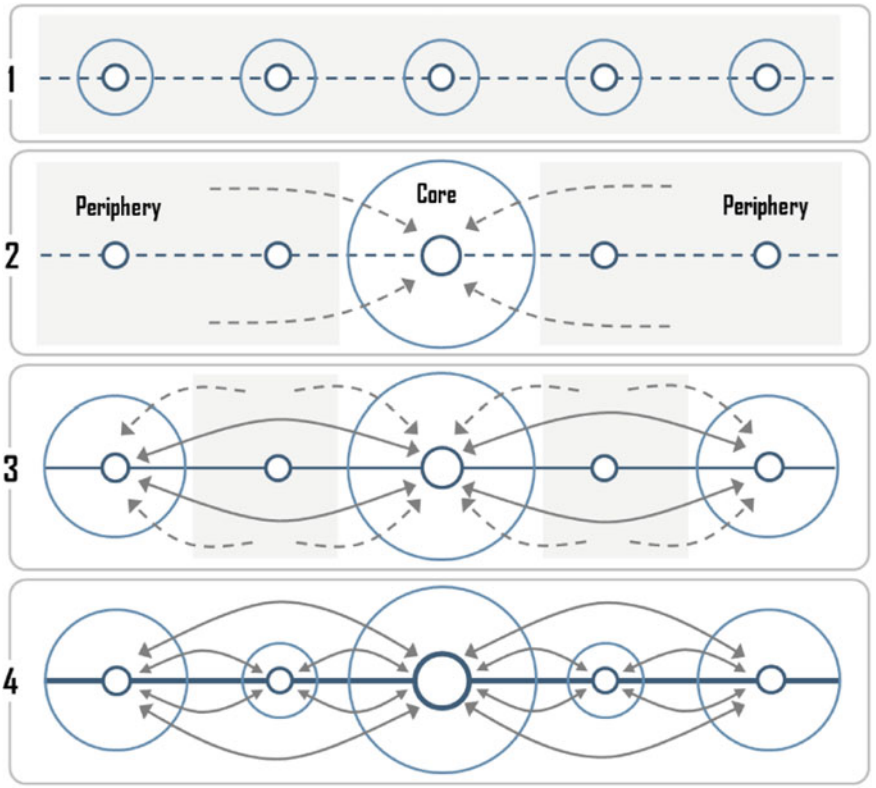

Fig. 1 Stages of development of functionally integrated "core-periphery" system in urban agglomeration [13]

on the basis of which a functionally integrated system of urban agglomeration is built in four stages (Fig. 1).

The pre-industrial stage (1) is a small-scale agricultural production with small community-type settlements fenced off from the outside world. At the early industrialization stage (2), capital is concentrated in the most developed city of the region, and industry, trade, financial and other services are growing. At the industrial stage (3) instead of a single center (core) of economic activity appears several due to the high cost of land in the region's main city and the need to reduce production costs, including labour remuneration. Transport infrastructure is being built between them and connections are being developed. By the post-industrial stage (4) the integration of the system of urban agglomerations, where models of specialization and division of labour are formed, high innovation activity for economic growth is supported [14].

The core-periphery model raises the issue of the availability (cost) of plots of land in urban agglomerations in different ways remote from the center, considered according to the neoclassical model of Alonso-Thuenen (bid rent theory), in which W. Alonso adapted the Thuenen's model to the urban land market in the form of

curves reflecting the behavior of companies and households depending on property prices. Based on it, W. Alonso claimed that the tendency of urban population to move to the suburbs was due to the reduced need to live close to the center because of increased income (the possibility of acquiring large plots in the suburbs) and lower transport costs (improved transport infrastructure) [15].

The Alonso-Thunen model provides a methodological justification for the theories of urban space structuring actively developed during the twentieth century, and the graph of household behavior when applying on its X-axis the concentric zone model of the city, proposed by E. Burgess, allows a new interpretation of the integrated system "core-periphery" by G. Friedman, which explains the process of formation of polycentric urban agglomeration step by step. The Burgess's concentric zones (central business; transitional; labour; residences and mansions; suburban) show the wave pattern of the region's space development impulses spreading from the centers (cores) of urban agglomerations to the regional periphery [16].

For almost one hundred years, the Burgess's urban zone classification has been repeatedly refined and reinterpreted in terms of the number of zones and their functional purpose. Taking this fact into account, this paper suggests the author's interpretation of urban agglomeration zones, which allows systematizing its housing stock by the level of availability and comfort (from the center to the outskirts) in relation to the objectives of the regional housing policy: (1) housing of the central district; (2) unfavorable housing; (3) medium housing; (4) favorable housing; (5) low-rise housing; (6) traditional housing of suburbs; (7) housing of the regional periphery.

Among the seven zones identified, the first five are directly related to urban agglomeration, while the sixth and seventh, being traditionally rural settlements, are more socially and economically attracted to urban agglomeration than to formal administrative (district) centers. The sixth and seventh zones are the main territorial resource for the development of the socio-economic space of the urban agglomeration. In particular, the directly adjacent sixth zone will eventually become part of its structure, and the seventh zone will take the place of the sixth, becoming an "associate member" of the agglomeration, supplying manpower based on commuting.

In order to understand the impact of centripetal and centrifugal forces on housing development in the urban agglomeration, it is advisable to briefly describe the housing stock of each of the seven zones. Housing in the central district (mostly of high quality) is a historical development that expresses the appearance of the city, preserved through modernization and reconstruction. The unfavorable housing zone is the backside of central district housing (often dilapidated and worn out) for low-income households, saving on transportation costs. The medium housing zone is more attractive to the majority of the population because of the better housing stock with a slight increase in price. In a favorable housing zone multi-storey districts are set up in accordance with modern requirements of comfort from class "standard" to "elite" in areas where it is convenient to carry out mass development. Outside it, low-rise housing is being complexly erected, which combines urban comfort with the advantages of country life [17]. In the areas of traditional suburbs and regional peripheries, housing is built individually, mostly as a rural residence, and

there is generally little difference in terms of improvement. But housing of traditional suburbs directly borders with urban development, sometimes intertwined with low-rise complexes, while housing of regional suburbs is at a sufficient distance from urban agglomerations and is located in villages or urban-type settlements.

The mutual impact of centripetal and centrifugal forces in urban agglomerations and the surrounding areas determines the changes in the housing sector in this part of the region as part of its socio-economic space. This paper proposes a model of distribution of centripetal and centrifugal forces in the urban agglomeration, built by transforming the "core-periphery" model of G. Friedman, supplemented by the city's concentric zones in the author's interpretation based on the E. Burgess approach, grouped according to the patterns of household behavior identified by W. Alonso (Fig. 2).

The author's model (scheme) graphically depicts distribution of centripetal and centrifugal forces in polycentric agglomeration formed on the basis of three centers

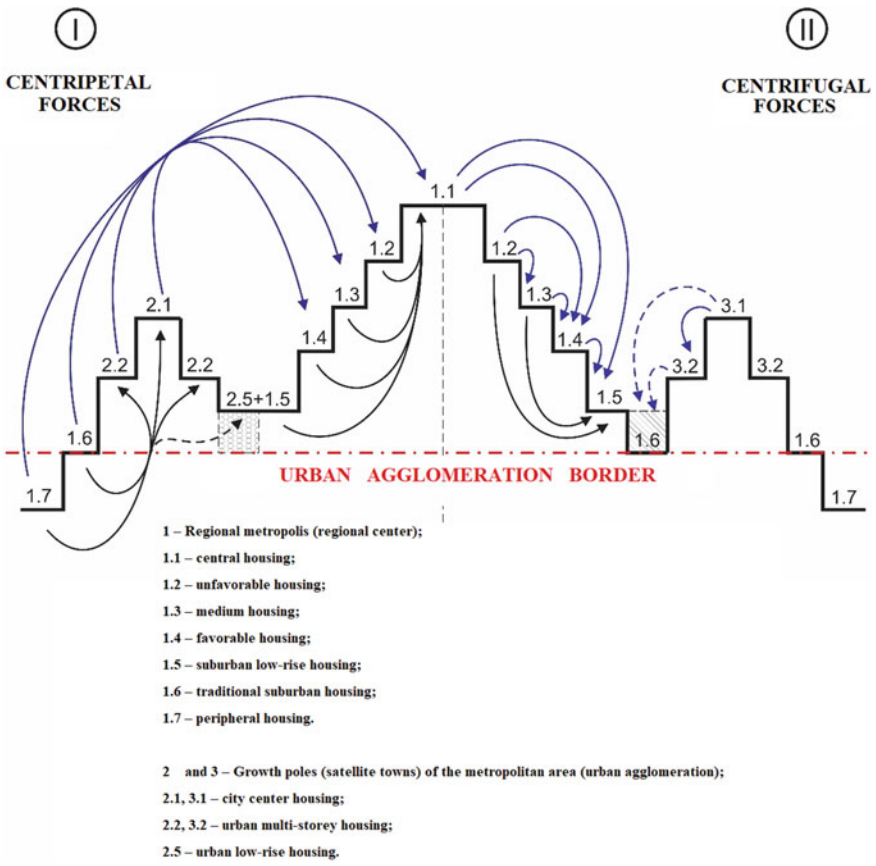

Fig. 2 Graphic model of centripetal and centrifugal forces distribution in urban agglomeration

(cores) of economic activity of the region with characteristic transformation of residential areas. Each of the three cities (1—regional metropole; 2 and 3—its satellites) has its own housing stock zoned according to the criterion of housing quality. The housing stock of the main city of the region (metropolis), which includes seven zones, is more differentiated due to the complexity of the spatial organization and larger size, in the satellite cities there are three zones—housing of the city center, urban multi-storey and low-rise suburban housing.

The left part of the scheme (I) shows how, under the influence of centripetal forces, a new center (core) is connected to a polycentric urban agglomeration by joining their low-rise housing zones (2.5 + 1.5). Agglomeration caused by centrifugal forces is demonstrated in the right part (II), where the metropolis complexly erects modern and comfortable neighborhoods for the population of the urban agglomeration in the zone of traditional suburban housing (1.6), bordering the zone of multi-storey housing of the satellite city (3.2).

Growth of urban agglomeration and increase in the number of centers (cores) of economic activity complicates the structure of housing stock and territorially changes the location of residential zones, expanding the range of choice for households to live more comfortably and stimulating the inflow of economically active population of the regional periphery. By increasing affordability of housing, housing policy provides necessary level of labour mobility, which contributes to the development of social and economic space of the region [18].

4 Conclusion

Regional development as a multi-component and complex process is largely determined by the behavior of urban agglomerations, which absorb the necessary resources from the surrounding space for structural transformation and formation of new centers (cores) of socio-economic growth. Increasing polycentricity of urban agglomerations strengthens the frame of regional space, which enhances their intensifying impact on the entire territory of the region.

Alongside the groups of innovative enterprises of the region's production complex, which are closely located and connected to the general infrastructure, called the poles of economic growth, a similar function is performed by some parts of urban agglomerations, which are considered as centers (cores) of their socio-economic development. The centers (cores) formed on the basis of sustainable interaction of organizations and social groups located within the local community begin to function as a kind of socio-economic clusters, where the level of comfort and infrastructure support of the housing sector is well above the average for the city.

The attractiveness of housing conditions and job growth around the centers (cores) stimulate the inflow of population from other areas of urban agglomeration and regional periphery, giving the construction sector an impulse to increase the volume of commissioning of multi-storey and low-rise housing in undeveloped territories. The growth of housing construction and the incorporation of new buildings into

the "body" of the urban agglomeration involves new contractors and related industries in the technological chain. The resulting multiplier effect serves as a source of greater influence of the growing center (core) of socio-economic activity in the urban agglomeration and enhances its polycentricity.

The regional housing policy, planning the construction of new residential complexes, builds a model of highly organized housing sector of urban agglomerations, which is built into the structure of the region's renewed social and economic space. The growth of the social vector leads to a shift in the strategic balance of territorial and production forces, allowing the housing policy to more actively influence the format of the spatial framework, priorities and intensity of socio-economic development of the region.

The author's graphic model of distribution of centripetal and centrifugal forces proposed in the paper shows the location of residential zones in the process of integration of centers (cores) into a single polycentric structure of urban agglomeration. It also defines the direction and nature of the impact of increasing urbanization in the region, identifying priority areas for housing policy, including the most promising areas of the regional periphery.

Socio-economic Ecosystems, Sustainable Economic Development and Digitalization of the Economy

Svetlana L. Sazanova

Abstract Modern economic science does not yet have a holistic theory explaining how to solve the problem of sustainable development of socio-economic systems in the context of new technologies and digitalization of the economy. In the article, the author explores new forms of business organization—the business ecosystem from the point of view of the role they play in the modern economy, how they affect the activities of economic entities and the sustainable development of the economy. The aim of the article is to study the ecosystem as an economic phenomenon, as a component of the country's socio-economic system, as a possible driver of sustainable economic development in the context of the digitalization of the economy. To achieve this goal, the following tasks are solved in the article: the phenomenon of the ecosystem in the economy is studied from the point of view of various scientific approaches; factors that impede and contribute to sustainable economic development are investigated; explores the role of digital technology in ensuring sustainable economic development. The study is based on the use of general scientific and specific research methods, such as: analysis, synthesis method, method of rational reconstruction of science, comparative analysis method, generalization method and others. The method of comparative analysis revealed differences in views on the essence of economic ecosystems of domestic and foreign scientists; the synthesis method allowed us to identify approaches to the study of economic ecosystems in modern economic science; the method of rational reconstruction of scientific knowledge made it possible to establish differences in relation to knowledge as a factor in economic development in economic studies of eastern and western economic thought; The generalization method has become the basis for the formulation of research results.

1 Introduction

One of the pressing problems of the modern global economy is the problem of sustainable economic development. Despite the development of new technologies, digitalization, artificial intelligence, no country in the world has yet been able to solve the problem of sustainable balanced development based on productivity growth. Actual phenomena of the modern economy that require in-depth research are new forms of business organization, their relationship with other components of the socio-economic system, business entities. One of these new forms of business organization are business ecosystems, entrepreneurial ecosystems, and socio-economic ecosystems that are developing on the basis of digital technologies. In modern economic science, a holistic theory of ecosystems in business has not yet developed, explaining what role they play in the modern economy, how they affect the activities of economic entities. This article fills this gap, which determines its relevance.

The aim of the article is to study the ecosystem as an economic phenomenon, as a component of the country's socio-economic system, as a possible driver of sustainable economic development in the context of the digitalization of the economy. To achieve this goal, the following tasks are solved in the article: the phenomenon of the ecosystem in the economy is studied from the point of view of various scientific approaches; factors that impede and contribute to sustainable economic development are investigated; explores the role of digital technology in ensuring sustainable economic development.

2 Methodology

The study is based on the use of general scientific and specific research methods, such as: analysis, synthesis method, method of rational reconstruction of science, comparative analysis method, generalization method and others. The method of comparative analysis revealed differences in views on the essence of economic ecosystems of domestic and foreign scientists; the synthesis method allowed us to identify approaches to the study of economic ecosystems in modern economic science; the method of rational reconstruction of scientific knowledge made it possible to establish differences in relation to knowledge as a factor in economic development in economic studies of eastern and western economic thought; The generalization method has become the basis for the formulation of research results.

3 Discussion and Results

The theory of socio-economic ecosystems is a relatively young, but gaining popularity, area of research in modern economic science. The rapidly developing methodological and theoretical tools of the theory allows us to study both new forms and methods of organizing and conducting economic activity, and the interaction of social, institutional, economic, cultural subsystems of society, taking into account the spatio-temporal factor. The methodology of the theory of socio-economic ecosystems is based on a combination of interdisciplinary and systemic approaches: the first determines the penetration into the economic analysis of the elements of the methodology of historical, evolutionary, cultural research, and the second allows you to identify the relationships between the components of socio-economic ecosystems, determine dynamics factors and build models for their development with taking into account the space-time factor.

A study of the behavior of business entities in socio-economic ecosystems has led to an increase in scientists' interest in phenomena that were previously outside the boundaries of economic research, such as the mentality of an economic entity, the values of economic activity, economic communications, etc. [1]. However, a holistic concept that reveals the relationship of mental models, values of economic activity and economic communications in socio-economic ecosystems has not yet been formed in domestic or foreign economic science, although the construction of such a concept seems to the author of the article quite relevant.

A great contribution to the development of the theory of socio-economic ecosystems was made by J. Moore, J. Baldwin, R. Adner, M. Jacobides, K. Kennamo, A. Haver, M. Castells, D. Richards, B. Allenby, R. Frosch, G. Kleiner, V. Dementiev, E. Ustyuzhanina, A. Kolesnikov, V. Ermolenko, D. Lanskaya, V. Karpinskaya, N. Smorodinskaya and others. Historically, the first concept of "business ecosystem" was proposed by Moore [2–4], which, in turn, used the concept of "biological ecosystem", introduced into the scientific circulation of A. Tensley. From the point of view of biological science, an "ecosystem" is a combination of compactly existing living organisms in relation to their environment [5], the ecosystem is in constant energy exchange with the surrounding natural environment, that is, it is an open system. A. Tensley, in turn, relied on the work of E. Burge, who proved that the systems of living organisms should be studied on the basis of a holistic methodology. Thus, the methodological holism of the philosopher C. Smuts was realized not only in the studies of the "old" American institutionalists, but also in biological science, and then returned to economic research [1]. According to J. Moore, the economic ecosystem is the economic community, consisting of the company itself, its consumers, suppliers, market intermediaries, channels of movement of goods, owners and other stakeholders, governmental and non-governmental organizations, and even competitors [6]. Later, Moore specified the concept of "entrepreneurial ecosystem" ("business ecosystem"), including in its structure the totality of producers, consumers, markets, products, processes, industry associations and departments, organizations, risks, power, and other aspects [4].

Modern human economic activity is characterized by a growing impact on the natural, social, cultural environment, not only within one country, but also at the international and even global levels. Awareness of this has led the study of economic phenomena and processes beyond the framework of, in fact, economic systems and has opened up great opportunities for interdisciplinary research. Having discovered the existence of the problem of "external effects" (by the example of environmental pollution), A. Pigou laid the foundation for studies of the relationship between economic and environmental systems and subsystems. As you know, A. Pigu proposed to solve the problem of externalities through taxes on producers of goods with negative external effects and subsidies for producers of goods with positive external effects. However, deeper studies have found that it is extremely difficult to create a methodology for evaluating external effects, and therefore the mechanism of such regulation, due to high structural uncertainty and cognitive limitations. Structural uncertainty lies in the fact that neither the parties to the transaction, nor third parties, nor even the courts and the expert community are aware of the likelihood of external effects, and the organic irrationality of economic agents does not allow to specify their content.

The desire to solve the problem of negative external effects, primarily environmental ones, contributed to the expansion and deepening of studies of the impact of industrial and intensive agricultural activities of people on the natural environment and the reverse effect of a changed natural environment on a person and his economic activity. As more and more new aspects and consequences of the interaction of economic and natural systems were revealed, an understanding was formed that this interaction is of a stable systemic nature. D. Richards, B. Allenby, R. Frosch believe that the main problem in the study of ecosystems is the determination of their boundaries, production and consumption methods in order to ultimately create environmentally compatible industrial ecosystems [7]. D. Richards, B. Allenby, and R. Frosch also note that industrial ecology recognizes the unique role of humans in creating complex artifacts and institutions that cause changes in materials and energy flows in both industrial and natural systems. Natural ecosystems, which provide raw materials for economic activity, also serve as sinks of waste products of producers and consumers in industrial activities. They believe that the study of natural ecological systems is important for understanding the interconnected natural and industrial systems. A study of industrial ecosystems provides an opportunity to answer the question of how production and consumption methods in an economy can be changed to create environmentally compatible industrial ecosystems [7]. R. Doshi, U. Divekar, and others draw attention to the fact that the modern practice of the consumption of natural resources is unstable and may ultimately lead to the disappearance of ecosystems. In their view, sustainable ecosystem management is necessary to ensure that the human and environmental needs of the present are met without compromising the ability of future generations to meet their own. They propose solving the problem of sustainable development of interacting industrial and natural ecosystems with the help of a mathematical model of an integrated environmental and economic system representing such sectors of our planet as households, the industrial sector and the energy production sector.

Another relevant aspect of the development of business ecosystems is digital technologies and the opportunities they provide. Digital technologies, platforms and applications expand the scope of communications, change the essence and content of the concepts of "product value", "company value", etc. On the one hand, in the modern world, every organization exists in several business ecosystems, which are dynamic networks of organizations, interacting with each other to create and exchange sustainable value for participants; on the other hand, modern ecosystems are an interdependent group of entities (i.e. people, things, enterprises) that use standardized digital platforms to interact with each other in order to achieve any commercial or civic goal.

Business ecosystems are a more flexible form of business interactions than previously known hybrid forms of business organization [8, 9]; they more quickly enable the creation of value chains, satisfy the market needs for new goods and services, but do not limit their participants in making strategic decisions.
